

JP1 Version 11

**JP1/Performance Management - Remote Monitor
for Platform Description, User's Guide and
Reference**

3021-3-A42-10(E)

Notices

■ Relevant program products

JP1/Performance Management - Manager (for Windows Server 2008 R2, Windows Server 2012, Windows Server 2016):

P-2A2C-AABL JP1/Performance Management - Manager 11-10

The above product includes the following:

P-CC2A2C-5ABL JP1/Performance Management - Manager 11-10

P-CC2A2C-5RBL JP1/Performance Management - Web Console 11-10

JP1/Performance Management - Manager (for CentOS 6 (x64), CentOS 7, Linux 6 (x64), Linux 7, Oracle Linux 6 (x64), Oracle Linux 7, SUSE Linux 12):

P-812C-AABL JP1/Performance Management - Manager 11-10

The above product includes the following:

P-CC812C-5ABL JP1/Performance Management - Manager 11-10

P-CC812C-5RBL JP1/Performance Management - Web Console 11-10

JP1/Performance Management - Manager (for AIX V6.1, AIX V7.1, AIX V7.2):

P-1M2C-AABL JP1/Performance Management - Manager 11-10

The above product includes the following:

P-CC1M2C-5ABL JP1/Performance Management - Manager 11-10

P-CC1M2C-5RBL JP1/Performance Management - Web Console 11-10

JP1/Performance Management - Remote Monitor for Platform (for Windows Server 2008 R2, Windows Server 2012, Windows Server 2016):

P-2A2C-GCBL JP1/Performance Management - Remote Monitor for Platform 11-10

The above product includes the following:

P-CC2A2C-5CBL JP1/Performance Management - Remote Monitor for Platform 11-10

P-CC2A2C-AJBL JP1/Performance Management - Base 11-10

JP1/Performance Management - Remote Monitor for Platform (for CentOS 6 (x64), CentOS 7, Linux 6 (x64), Linux 7, Oracle Linux 6 (x64), Oracle Linux 7, SUSE Linux 12):

P-812C-GCBL JP1/Performance Management - Remote Monitor for Platform 11-10

The above product includes the following:

P-CC812C-5CBL JP1/Performance Management - Remote Monitor for Platform 11-10

P-CC812C-AJBL JP1/Performance Management - Base 11-10

These products include parts that were developed under licenses received from third parties.

■ Trademarks

HITACHI, Cosminexus, HiRDB, JP1, OpenTP1, uCosminexus are either trademarks or registered trademarks of Hitachi, Ltd. in Japan and other countries.

Active Directory is either a registered trademark or a trademark of Microsoft Corporation in the United States and/or other countries.

AMD, AMD Opteron, and combinations thereof, are trademarks of Advanced Micro Devices, Inc.

IBM is trademark of International Business Machines Corporation, registered in many jurisdictions worldwide.

IBM, AIX are trademarks of International Business Machines Corporation, registered in many jurisdictions worldwide.

IBM, AIX 5L are trademarks of International Business Machines Corporation, registered in many jurisdictions worldwide.

IBM, DB2 are trademarks of International Business Machines Corporation, registered in many jurisdictions worldwide.

IBM, WebSphere are trademarks of International Business Machines Corporation, registered in many jurisdictions worldwide.

Intel is a trademark of Intel Corporation in the U.S. and/or other countries.

Internet Explorer is either a registered trademark or trademark of Microsoft Corporation in the United States and/or other countries.

Itanium is a trademark of Intel Corporation in the United States and other countries.

Linux(R) is the registered trademark of Linus Torvalds in the U.S. and other countries.

Microsoft and SQL Server are either registered trademarks or trademarks of Microsoft Corporation in the United States and/or other countries.

Microsoft and Visual C++ are either registered trademarks or trademarks of Microsoft Corporation in the United States and/or other countries.

Microsoft and Visual Studio are either registered trademarks or trademarks of Microsoft Corporation in the United States and/or other countries.

Microsoft is either a registered trademark or a trademark of Microsoft Corporation in the United States and/or other countries. Microsoft Exchange server is a product name of Microsoft Corporation in the U.S. and other countries.

ODBC is Microsoft's strategic interface for accessing databases.

Oracle and Java are registered trademarks of Oracle and/or its affiliates.

Red Hat is a trademark or a registered trademark of Red Hat Inc. in the United States and other countries.

RSA is either a registered trademark or a trademark of EMC Corporation in the United States and/or other countries.

All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc., in the United States and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems, Inc.

SUSE is a registered trademark or a trademark of SUSE LLC in the United States and other countries.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Win32 is either a registered trademark or a trademark of Microsoft Corporation in the United States and/or other countries.

Windows is either a registered trademark or a trademark of Microsoft Corporation in the United States and/or other countries.

Windows Server is either a registered trademark or a trademark of Microsoft Corporation in the United States and/or other countries.

Other company and product names mentioned in this document may be the trademarks of their respective owners.

■ Restrictions

Information in this document is subject to change without notice and does not represent a commitment on the part of Hitachi. The software described in this manual is furnished according to a license agreement with Hitachi. The license agreement contains all of the terms and conditions governing your use of the software and documentation, including all warranty rights, limitations of liability, and disclaimers of warranty.

Material contained in this document may describe Hitachi products not available or features not available in your country.

No part of this material may be reproduced in any form or by any means without permission in writing from the publisher.

■ Microsoft product name abbreviations

This manual uses the following abbreviations for Microsoft product names.

Abbreviation		Full name or meaning
Internet Explorer		Windows(R) Internet Explorer(R)
Visual C++		Microsoft(R) Visual C++(R)
Visual Studio		Microsoft(R) Visual Studio(R)
Win32		Win32(R)
Windows Server 2003	Windows Server 2003 (x64)	Microsoft(R) Windows Server(R) 2003, Enterprise x64 Edition
		Microsoft(R) Windows Server(R) 2003, Standard x64 Edition
		Microsoft(R) Windows Server(R) 2003 R2, Enterprise x64 Edition
		Microsoft(R) Windows Server(R) 2003 R2, Standard x64 Edition
	Windows Server 2003 (x86)	Microsoft(R) Windows Server(R) 2003, Enterprise Edition
		Microsoft(R) Windows Server(R) 2003, Standard Edition
		Microsoft(R) Windows Server(R) 2003 R2, Enterprise Edition
		Microsoft(R) Windows Server(R) 2003 R2, Standard Edition
Windows Server 2008	Windows Server 2008	Microsoft(R) Windows Server(R) 2008 Enterprise
		Microsoft(R) Windows Server(R) 2008 Standard
	Windows Server 2008 R2	Microsoft(R) Windows Server(R) 2008 R2 Datacenter
		Microsoft(R) Windows Server(R) 2008 R2 Enterprise
		Microsoft(R) Windows Server(R) 2008 R2 Standard

Abbreviation		Full name or meaning
Windows Server 2012	Windows Server 2012	Microsoft(R) Windows Server(R) 2012 Datacenter
		Microsoft(R) Windows Server(R) 2012 Standard
	Windows Server 2012 R2	Microsoft(R) Windows Server(R) 2012 R2 Datacenter
		Microsoft(R) Windows Server(R) 2012 R2 Standard
Windows Server 2016		Microsoft(R) Windows Server(R) 2016 Datacenter
		Microsoft(R) Windows Server(R) 2016 Standard
WSFC		Microsoft(R) Windows Server(R) Failover Cluster

Windows Server 2003, Windows Server 2008, Windows Server 2012, and Windows Server 2016 are sometimes referred to collectively as *Windows*.

Summary of amendments

The following table lists changes in this manual (3021-3-A42-10(E)) and product changes related to this manual.

Changes	Location
The following OS is now supported as a monitored OS: <ul style="list-style-type: none"> AIX V7.2 	--
The function to remotely monitor the operating statuses of hosts that support the ICMP protocol (health check monitoring) was added.	<i>1.2.1, 1.2.1(1), 3.1.1(4)(c), 3.1.1(7), 3.1.4(2)(a), 3.1.4(3), 3.1.4(3)(a), 3.1.4(3)(b), 3.1.4(3)(c), 3.1.4(3)(d), 3.1.4(3)(e), 3.2.1(4)(a), 3.2.1(6), 3.2.4(3)(a), 3.2.4(4), 3.2.4(4)(a), 3.2.4(4)(b), 3.2.4(4)(c), 3.2.4(4)(d), 3.2.4(4)(e), 3.6.3(1), 3.6.3(2), Chapter 7, Appendix E.3, Appendix O</i>
The following OSs are now supported: <ul style="list-style-type: none"> Microsoft(R) Windows Server(R) 2016 Datacenter Microsoft(R) Windows Server(R) 2016 Standard 	<i>3.1.1(1), 3.1.1(4)(c), 3.1.1(5)(a), 3.1.1(5)(d), 3.1.5(1)(b), 3.1.5(2), 3.1.5(3), 3.1.5(4), 5.3.1(1)(a), 5.3.4(16)</i>
An explanation was added about the port numbers used for WMI.	<i>Appendix D.2(1)(a)</i>
The following property was added to the instance environment setting items for PFM - RM for Platform (for Windows): <ul style="list-style-type: none"> Use_Processor_Information_Object 	<i>Appendix E.2, Appendix J.1(9)</i>
An explanation was added about the action to take when the following problem occurs: <ul style="list-style-type: none"> The message KAVL17016-W Performance data was not saved to the Store database because it is the same as previous performance data. is output to the common message log. If the OS of the monitored host is UNIX, a timeout occurs when collecting performance data. 	<i>8.4, 9.2.3(3), 9.2.5</i>

Legend:

--: Not applicable

In addition to the above changes, minor editorial corrections were made.

Preface

This manual describes the functions of JP1/Performance Management - Remote Monitor for Platform and the records that are collected by it.

■ Intended readers

This manual describes JP1/Performance Management - Remote Monitor for Platform. The manual is intended for the following readers:

- Users who are interested in designing or building an operation monitoring system
- Users who are interested in defining conditions for collecting performance data
- Users who are interested in defining reports and alarms
- Users who are interested in referencing performance data that is collected for the purpose of monitoring a system
- Users who are interested in developing and evaluating corrective measures to take for a system based on monitoring results, or users who are interested in directing the implementation of such measures

This manual assumes that the reader is knowledgeable about the operation of the monitored systems and is familiar with their operating systems.

For details about setting up and operating a system that uses JP1/Performance Management, also see the following manuals:

- *JP1/Performance Management Planning and Configuration Guide*
- *JP1/Performance Management User's Guide*
- *JP1/Performance Management Reference*

■ Organization of this manual

This manual is organized into the following parts.

This manual is applicable to both Windows and UNIX operating systems (OSs). Any information specific to one of the OSs only is indicated as such in the manual.

PART 1: Overview

PART 1 provides an overview of JP1/Performance Management - Remote Monitor for Platform.

PART 2: Setup and Operation

PART 2 explains how to install and set up JP1/Performance Management - Remote Monitor for Platform, as well as how to uninstall and unsetup JP1/Performance Management - Remote Monitor for Platform. It also explains how to back up and restore files, how to collect process operating status information, and how to operate JP1/Performance Management - Remote Monitor for Platform in a cluster system.

PART 3: Reference

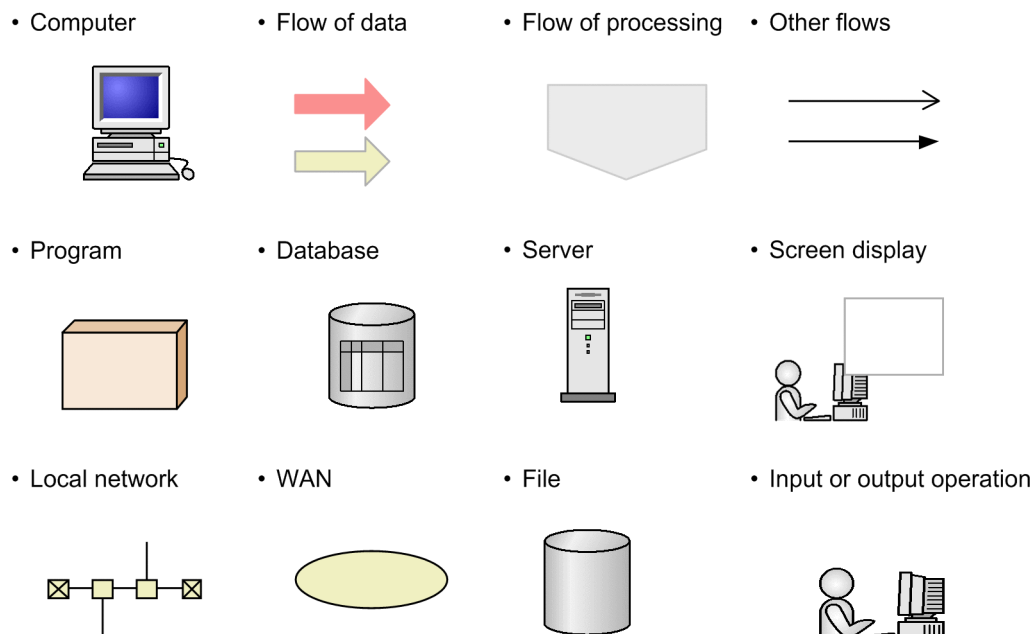

PART 3 describes the monitoring templates, records, and messages for JP1/Performance Management - Remote Monitor for Platform.

PART 4: Troubleshooting

PART 4 describes the procedures for handling problems in JP1/Performance Management - Remote Monitor for Platform.

■ Conventions: Diagrams

This manual uses the following conventions in diagrams:

■ Conventions: Fonts and symbols

The following table explains the text formatting conventions used in this manual:

Text formatting	Convention
Bold	<p>Bold characters indicate text in a window, other than the window title. Such text includes menus, menu options, buttons, radio box options, or explanatory labels. For example:</p> <ul style="list-style-type: none">• From the File menu, choose Open.• Click the Cancel button.• In the Enter name entry box, type your name.
<i>Italic</i>	<p>Italic characters indicate a placeholder for some actual text to be provided by the user or system. For example:</p> <ul style="list-style-type: none">• Write the command as follows: <code>copy source-file target-file</code>• The following message appears: <code>A file was not found. (file = file-name)</code> <p>Italic characters are also used for emphasis. For example:</p> <ul style="list-style-type: none">• Do <i>not</i> delete the configuration file.
Monospace	<p>Monospace characters indicate text that the user enters without change, or text (such as messages) output by the system. For example:</p> <ul style="list-style-type: none">• At the prompt, enter <code>dir</code>.• Use the <code>send</code> command to send mail.

Text formatting	Convention
Monospace	<ul style="list-style-type: none"> The following message is displayed: The password is incorrect.

The following table explains the symbols used in this manual:

Symbol	Convention
	In syntax explanations, a vertical bar separates multiple items, and has the meaning of OR. For example: A B C means A, or B, or C.
{ }	In syntax explanations, curly brackets indicate that only one of the enclosed items is to be selected. For example: { A B C } means only one of A, or B, or C.
[]	In syntax explanations, square brackets indicate that the enclosed item or items are optional. For example: [A] means that you can specify A or nothing. [B C] means that you can specify B, or C, or nothing.
. . .	In coding, an ellipsis (. . .) indicates that one or more lines of coding have been omitted. In syntax explanations, an ellipsis indicates that the immediately preceding item can be repeated as many times as necessary. For example: A, B, B, . . . means that, after you specify A, B, you can specify B as many times as necessary.
()	Parentheses indicate the range of items to which the vertical bar () or ellipsis (. . .) is applicable.

Conventions for mathematical expressions

This manual uses the following symbols in mathematical expressions:

Symbol	Meaning
×	Multiplication sign
÷	Division sign

■ Conventions: Version numbers

The version numbers of Hitachi program products are usually written as two sets of two digits each, separated by a hyphen. For example:

- Version 1.00 (or 1.0) is written as 01-00.
- Version 2.05 is written as 02-05.
- Version 2.50 (or 2.5) is written as 02-50.
- Version 12.25 is written as 12-25.

The version number might be shown on the spine of a manual as *Ver. 2.00*, but the same version number would be written in the program as 02-00.

Contents

Notices	2
Summary of amendments	6
Preface	7

Part 1: Overview

1	Overview of PFM - RM for Platform	17
1.1	Purposes of performance monitoring using PFM - RM for Platform	18
1.1.1	Finding the causes of system overload and identifying its effects on the system resources	18
1.1.2	Monitoring to see if the system is running normally	19
1.2	Features of PFM - RM for Platform	20
1.2.1	Monitoring multiple hosts remotely	20
1.2.2	Collecting performance data by attribute	22
1.2.3	Storing performance data	22
1.2.4	Using collected performance data effectively	23
1.2.5	Integrating monitoring and analysis of performance data for multiple monitored hosts	24
1.2.6	Easy setting of alarms and reports	25
1.2.7	Applicable to cluster systems	25
2	Functions of PFM - RM for Platform	27
2.1	Collecting and managing performance data	28
2.1.1	Flow of performance data collection	28
2.2	How to monitor performance	31
2.2.1	Example of monitoring a processor	31
2.2.2	Example of monitoring memory	36
2.2.3	Example of monitoring the disk	39
2.2.4	Example of monitoring the network	41
2.2.5	Example of monitoring processes and services	43

Part 2: Setup and Operation

3	Installation and Setup	47
3.1	Installation and setup of the Windows edition	48
3.1.1	Issues to consider before installing the Windows edition	48
3.1.2	Flow of installation and setup for the Windows edition	60
3.1.3	Installation procedure for the Windows edition	61
3.1.4	Setup procedure for the Windows edition	63

3.1.5	WMI connection setting method (when both the PFM - RM host and the monitored host are running Windows)	85
3.1.6	SSH connection setting method for Windows (when the PFM - RM host is running Windows and the monitored host is running UNIX)	91
3.1.7	Notes about installation and setup of the Windows edition	98
3.2	Installation and setup of the UNIX edition	101
3.2.1	Issues to consider before installing the UNIX edition	101
3.2.2	Flow of installation and setup for the UNIX edition	108
3.2.3	Installation procedure for the UNIX edition	109
3.2.4	Setup procedure for the UNIX edition	111
3.2.5	SSH (for UNIX) connection setting method	128
3.2.6	Notes about installation and setup of the UNIX edition	135
3.3	Uninstallation and unsetup of the Windows edition	137
3.3.1	Issues to consider before uninstalling and canceling the setup for the Windows edition	137
3.3.2	Procedure for canceling the setup for the Windows edition	138
3.3.3	Procedure for uninstalling the Windows edition	140
3.4	Uninstallation and unsetup of the UNIX edition	142
3.4.1	Issues to consider before uninstalling and canceling the setup for the UNIX edition	142
3.4.2	Procedure for canceling the setup for the UNIX edition	142
3.4.3	Procedure for uninstalling the UNIX edition	145
3.5	Changing the PFM - RM for Platform system configuration	147
3.6	Changing the PFM - RM for Platform operation method	148
3.6.1	Changing performance data storage locations	148
3.6.2	Updating an instance environment	149
3.6.3	Updating a monitoring target	153
3.7	Backing up and restoring PFM - RM for Platform	158
3.7.1	Backing up	158
3.7.2	Restoring	159
3.8	Settings for using a Web browser to reference manuals	161
3.8.1	Setup for referencing manuals	161
3.8.2	How to view manuals	162

4 Collecting Process Operation Status Information 163

4.1	Setup for collecting process operation status information	164
4.1.1	Setup using the Agents tree	164
4.1.2	Setting up monitoring targets in the Agents tree	164
4.1.3	Deleting monitoring target settings in Agents tree	171
4.1.4	Using an application definition template in the Agents tree	171
4.1.5	Setting up collection in Services	175
4.1.6	Setting up a monitoring target in Services	175
4.1.7	Checking or modifying the settings for monitoring targets in Services	180
4.1.8	Deleting the settings for monitoring targets in Services	180

4.1.9	Setup using non-interactive commands	181
4.1.10	Using commands to set up monitoring targets	181
4.1.11	Using commands to delete settings for a monitoring target	183
4.1.12	Specifying whether process or service names to be used as monitoring targets will be case-sensitive	185
4.2	Example of the procedure to follow when an alarm is issued during the collection of process operation status information	187
5	Operation in a Cluster System	189
5.1	Configuration of PFM - RM for Platform in a cluster system	190
5.2	Processing when a failover occurs	192
5.2.1	Failover when an error occurs at the PFM - RM host	192
5.2.2	Effects of PFM - Manager shutdown and the action to take	193
5.3	Installation and setup in a cluster system (for Windows)	195
5.3.1	Items to be checked before installing in a cluster system (for Windows)	195
5.3.2	Flow of installation and setup in a cluster system (for Windows)	199
5.3.3	Installation procedure in a cluster system (for Windows)	200
5.3.4	Setup procedure in a cluster system (for Windows)	200
5.3.5	WMI connection setting method (when both the PFM - RM host and the monitored host are running Windows) in a cluster system	207
5.3.6	SSH connection setting method in a cluster system (when the PFM - RM host is running Windows and the monitored host is running UNIX) (for Windows)	207
5.4	Installation and setup in a cluster system (for UNIX)	208
5.4.1	Items to be checked before installing in a cluster system (for UNIX)	208
5.4.2	Flow of installation and setup in a cluster system (for UNIX)	211
5.4.3	Installation procedure in a cluster system (for UNIX)	213
5.4.4	Setup procedure in a cluster system (for UNIX)	213
5.4.5	SSH connection setting method in a cluster system (for UNIX)	220
5.5	Uninstallation and unsetup in a cluster system (for Windows)	221
5.5.1	Flow of uninstallation and unsetup in a cluster system (for Windows)	221
5.5.2	Unsetup procedure in a cluster system (for Windows)	222
5.5.3	Uninstallation procedure in a cluster system (for Windows)	226
5.6	Uninstallation and unsetup in a cluster system (for UNIX)	227
5.6.1	Flow of uninstallation and unsetup in a cluster system (for UNIX)	227
5.6.2	Unsetup procedure in a cluster system (for UNIX)	228
5.6.3	Uninstallation procedure in a cluster system (for UNIX)	233
5.7	Changing the PFM - RM for Platform system configuration	234
5.8	Changing the PFM - RM for Platform operation method in a cluster system	235
5.8.1	Updating an instance environment in a cluster system	235
5.8.2	Updating a monitoring target in a cluster system	236
5.8.3	Importing and exporting the logical host environment definition file in a cluster system	237

Part 3: Reference

6 Monitoring Template 239

Overview of the monitoring template	240
Format of alarm explanations	241
List of alarms	242
Application Status	245
Available Memory	247
CPU Usage	248
Disk Busy %	249
Disk Free Size	251
Disk Service Time	253
Disk Space	254
I/O Wait Time	255
Kernel CPU	256
Network Received	257
Page Faults	259
Pagescans	260
Process Existence	261
Processor Queue	263
Run Queue	264
Service Stop	265
Service Stop(dsp nm)	267
Swap Outs	269
Target Host Status	270
Used Swap Mbytes	271
User CPU	273
Format of report explanations	274
Organization of report directories	275
List of reports	277
Application Process Count (historical report indicating the operation status of each process and service of an application)	279
Application Process Status (real-time report indicating the operation status of each process and service of an application)	280
Application Status (real-time report indicating the operation status of an application)	281
Avg Disk Time Status (real-time report indicating the average I/O time for the physical disk)	282
Avg Disk Time Status (historical report indicating the average I/O time for the physical disk)	283
CPU Per Processor Status (real-time report indicating the processor usage rate for each processor)	284
CPU Used Status (real-time report indicating the CPU usage status)	285
CPU Used Status (historical report indicating the CPU usage status (1 month))	287
CPU Used Status (historical report indicating the CPU usage status (1 hour))	288
CPU Used Status (Multi-Agent) (historical report indicating the CPU usage status in multiple systems (1 month))	289
CPU Used Status (Multi-Agent) (historical report indicating the CPU usage status in multiple systems (1 day))	290
Free Megabytes - Logical Disk (real-time report indicating the available area on the logical disk)	291
Free Megabytes - Logical Disk (historical report indicating the available area on the logical disk)	292

Memory Paging Status (real-time report indicating information about memory and paging)	293
Memory Paging Status (historical report indicating information about memory and paging (1 day))	295
Memory Paging Status (historical report indicating information about memory and paging (1 hour))	297
Memory Used Status (real-time report indicating the physical memory usage status in the system)	299
Memory Used Status (historical report indicating the physical memory usage status in the system (1 day))	301
Memory Used Status (historical report indicating the physical memory usage status in the system (1 hour))	303
Memory Used Status (Multi-Agent) (historical report indicating the physical memory usage status in multiple systems (1 month))	305
Memory Used Status (Multi-Agent) (historical report indicating the physical memory usage status in multiple systems (1 day))	306
Network Data (real-time report indicating the status of communication between networks)	307
Network Data (historical report indicating the status of communication between networks)	308
Physical Disk Busy Status (real-time report indicating the length of time the disk was busy)	309
Physical Disk Busy Status (historical report indicating the length of time the disk was busy)	310
Pool Nonpaged Status (real-time report indicating the size of physical memory in the system that cannot be paged out)	311
Pool Nonpaged Status (historical report indicating the size of physical memory in the system that cannot be paged out)	313
System Overview (real-time report indicating the system operation status)	315
System Overview (historical report indicating the system operation status)	317
Target Host Status (historical report indicating the status of the connection to the monitored host and information about the OS of the monitored host)	319

8.1	Message format 374
8.1.1	Format of output messages 374
8.1.2	Format of message explanations 375
8.2	Message output destinations 377
8.3	List of messages output to the Windows event log and syslog 380
8.4	Messages 381

Part 4: Troubleshooting

9	Error Handling Procedures 393
9.1	Error handling procedures 394
9.2	Troubleshooting 395
9.2.1	The Remote Monitor Collector service of PFM - RM does not start 395
9.2.2	Failure Audit (Event ID: 4625 or 4776) is recorded in the Windows security event log. 396
9.2.3	PFM - RM for Platform was started, but no performance data is being collected 396
9.2.4	Alarms related to process monitoring are not reported as intended 402
9.2.5	The message "KAVL17016-W Performance data was not saved to the Store database because it is the same as previous performance data." is output to the common message log 402
9.2.6	Troubleshooting other problems 404
9.3	Log information to be collected for troubleshooting 405
9.3.1	Types of log information to be collected 405
9.3.2	Log files and directories to check 406
9.4	Data to be collected for troubleshooting 412
9.4.1	Data to be collected from a Windows environment 412

Overview of PFM - RM for Platform

This chapter provides an overview of PFM - RM for Platform.

1.1 Purposes of performance monitoring using PFM - RM for Platform

This section describes the purposes of using PFM - RM for Platform to monitor performance.

PFM - RM for Platform remotely monitors the performance of application servers. Performance monitoring is indispensable for maintaining stable system operations.

Specifically, performance monitoring involves the following tasks:

- Finding the causes of system overloading and identifying the effects of overloading on the system resources
- Monitoring the system to see whether it is running normally

By installing PFM - RM for Platform and monitoring your system's performance, you can identify the causes of system overloads and identify their effects on the system resources.

To use PFM - RM for Platform, you need PFM - Manager, PFM - Base, and PFM - Web Console. However, if you install PFM - RM for Platform on the same host as for PFM - Manager, there is no need to install PFM - Base.

1.1.1 Finding the causes of system overload and identifying its effects on the system resources

If the system load is high for specific reasons, you must restore the system to its normal status in order to minimize adverse effects on the entire system. Therefore, finding the causes of system overloads and identifying their effects on the system resources are important tasks for maintaining stable system operation.

If a performance problem arises, resulting in high system loading, possible causes are as follows:

- There is a memory shortage.
- A program is monopolizing use of specific resources.
- A subsystem has failed or is configured incorrectly.
- There is fluctuation in loading among subsystems.

Obtaining the statuses of the following system resources will assist in correcting these causes:

- Processor
- Memory
- Disk
- Network

PFM - RM for Platform can identify the system resources that are linked to the causes of system overloads by changing various conditions of performance monitoring (such as the number of users that are connected concurrently) and monitoring performance continuously.

Identifying the status of system resources is also useful for evaluating future system operation, such as when you change or adjust the system configuration or when you plan to upgrade the system's resources.

1.1.2 Monitoring to see if the system is running normally

To maintain stable system operation, it is important not only to correct the causes of system overloads but also to check routinely to see if the system is running normally.

You can check whether the system is running normally by monitoring the following operations:

- System-provided processes
- Invalid system processes
- Services required by the system

1.2 Features of PFM - RM for Platform

The following are the principal features of PFM - RM for Platform:

- Monitors multiple hosts remotely
- Collects and manages performance data by attribute
- Stores performance data
- Uses the collected performance data effectively
- Integrates monitoring and analysis of performance data for multiple monitored hosts
- Easy setting of alarms and reportsIs applicable to cluster systems

The subsections below describe these features.

1.2.1 Monitoring multiple hosts remotely

PFM - RM for Platform can be used to monitor performance remotely.

Remote monitoring is a function for monitoring the operation status of remote servers from a local host without having to install an agent at each application server.

This function enables you to monitor performance data without having to change the system configuration of the monitored application servers (hosts), because there is no need to install PFM - RM for Platform at the application servers. A single PFM - RM for Platform can collect and manage performance data for multiple hosts, and multiple instances of PFM - RM for Platform can collect and manage performance data for the same host.

In Performance Management, a host that is monitored by PFM - RM for Platform is called a *monitored host*.

PFM - RM for Platform running in a Windows environment can remotely monitor hosts running in a Windows or UNIX environment. However, PFM - RM for Platform running in a UNIX environment can remotely monitor hosts running in a UNIX environment only.

For details about the OS environments in which PFM - RM for Platform supports monitoring, see [3.1.1 Issues to consider before installing the Windows edition](#) or [3.2.1 Issues to consider before installing the UNIX edition](#).

You can also make the host on which PFM - RM for Platform is running the monitored host.

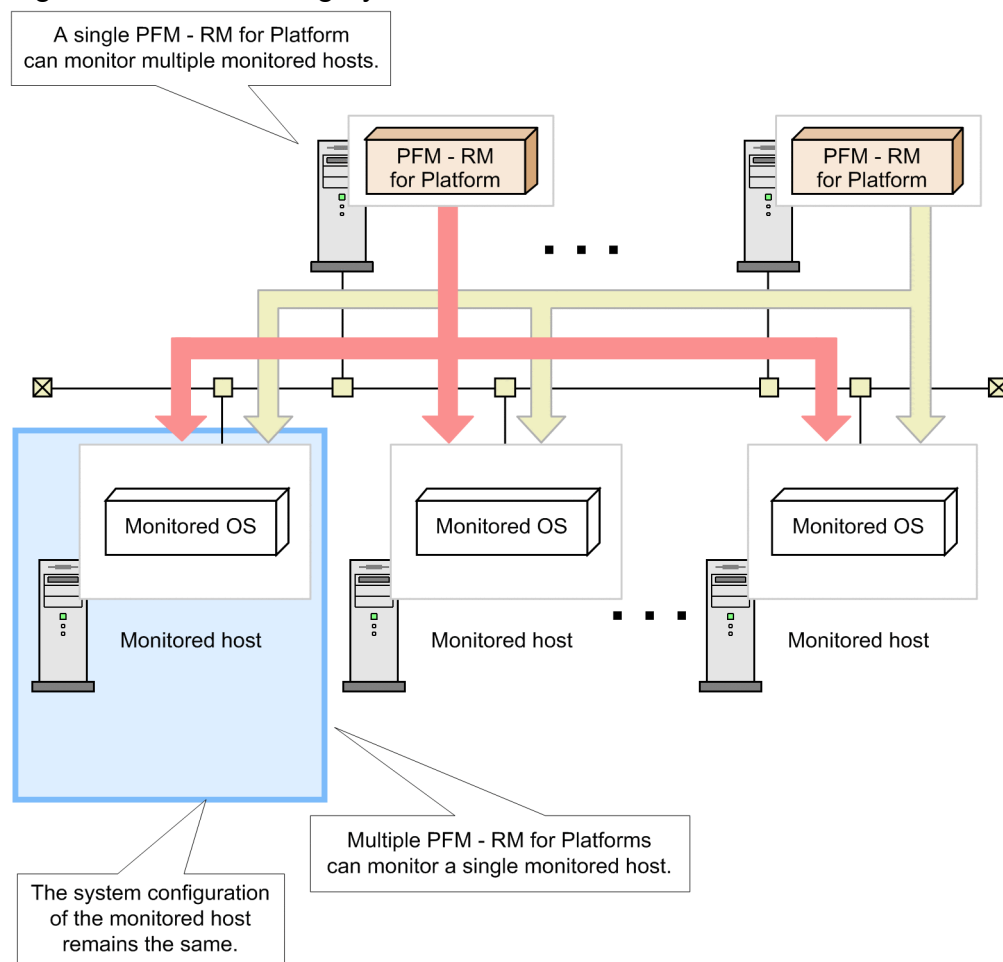

Furthermore, the use of the health check function of Performance Management enables you to remotely monitor the operating statuses of hosts and hardware equipment that support the ICMP protocol (can communicate through the `ping` command) (*health check monitoring*). Health check monitoring remotely monitors the operating status of the monitored host through a health check agent on the connection-target PFM - Manager.

Note that health check monitoring does not collect performance data.

For details about the health check function, see the chapter that describes the detection of failures in the *JPI/Performance Management User's Guide*.

The following figure illustrates monitoring of multiple monitored hosts by multiple instances of PFM - RM for Platform.

Figure 1–1: Monitoring by PFM - RM for Platform

Legend:

➡ and ➡ : Indicate performance monitoring.

(1) Common account information that enables multiple instance environments and monitoring targets to be centrally managed

PFM - RM for Platform uses the account information set up on the PFM - RM host to connect to monitoring targets remotely. Account information used by PFM - RM for Platform is classified into two types. The first is account information that is managed separately for each instance environment or monitoring target. The second is account information that is common to multiple instance environments and monitoring targets. Centrally managing common account information[#] is more efficient. For example, when changing the passwords for instance environments and monitoring targets, you only need to change the common account information that is centrally managed.

#

In health check monitoring, the common account information cannot be used. (Even if the common account information is set up, it is ignored.)

Account information used by PFM - RM for Platform (individual account information and common account information)

Remote connection by PFM - RM for Platform needs account information for instance environments (for Windows) and for monitoring targets within the instance environments.

To use individual account information, set up account information separately for each instance environment and for each monitoring target.

To use common account information, set up account information common to all instance environments and monitoring targets (for Windows and UNIX). You can specify whether to use common account information when setting up an instance environment or monitoring target.

Important

As common account information is used for all monitoring targets, there is a risk of greater negative impact if it is leaked. To avoid such a risk, determine whether to use common account information after considering security measures and information management.

1.2.2 Collecting performance data by attribute

In PFM - RM for Platform, performance data is collected in a format called *records*. A record is a unit for storing collected performance data in a database.

The types of performance data that can be collected have already been defined in PFM - RM for Platform. You use PFM - Web Console to select the records you wish to have collected. For details about how to use PFM - Web Console to select the records to be collected, see the chapter that describes management of operation monitoring data in the *JPI/Performance Management User's Guide*.

Records are classified into two types, according to the characteristics of the performance data to be collected.

- Product Interval record type

For records of the Product Interval record type, the system collects performance data for a specified interval, such as the CPU usage rate over 5 minutes. You can use these records to analyze changes or trends in the system status over time.

The Product Interval record type is referred to hereafter as the *PI record type*.

- Product Detail record type

For records of the Product Detail record type, the system collects performance data that indicates the system status at a specific point in time, such as detailed information about a host that is currently being monitored. You can use these records to obtain a snapshot of the system status at a particular time.

The Product Detail record type is referred to hereafter as the *PD record type*.

Each record is further divided into smaller units called *fields*. In Performance Management, records and fields are referred to collectively as a *data model*. For details about each record, see [7. Records](#).

1.2.3 Storing performance data

Collected performance data is stored in PFM - RM for Platform's database in the format of records. This database is called the *Store database*. You can use the performance data stored in the Store database to analyze trends in the operation status of the monitored hosts over time, such as from a point in the past up to the current time.

You use PFM - Web Console to set how performance data stored in the Store database is to be managed. For details about using PFM - Web Console to manage performance data, see the chapter that describes management of operation monitoring data in the *JPI/Performance Management User's Guide*.

1.2.4 Using collected performance data effectively

PFM - RM for Platform enables you to use the performance data collected from monitored hosts effectively, such as for analyzing and identifying trends and the host's operation status.

(1) Graphically displaying the operation status at monitored hosts

By using PFM - Web Console, you can process and display in a graphical format various types of performance data collected by PFM - RM for Platform, such as the CPU usage rate. Because this feature enables you to check trends and changes in collected and summarized performance data graphically, you can easily analyze the operation status of multiple hosts.

In Performance Management, data that is processed and displayed in a graphical format is called a *report*. There are two types of reports:

- *Real-time reports*

A real-time report indicates the current status of monitored hosts.

This type of report is used to check the current status of the system and for possible problems. Performance data that is current at the time when such a report is displayed is depicted in a real-time report.

- *Historical reports*

A historical report indicates the status of monitored hosts over a period of time, such as from some point in the past up to the present.

This type of report is used to analyze trends in the operation status of the system. Collected performance data stored in PFM - RM for Platform's Store database is used to display historical reports.

(2) Taking appropriate action in the event of an operational problem at a monitored host

In the event of a problem at a monitored host, such as insufficient system resources, you can take appropriate action on the basis of judgment conditions and threshold values set by PFM - RM for Platform.

For example, you could define that a 90% usage rate of the physical CPU is to be set as the threshold value for a failure condition and that an email notification is to be sent when the threshold value is reached. Whenever this failure condition occurs, the system administrator will be notified of the problem in a timely manner.

If you set a judgment condition, as in this example, the appropriate action is taken automatically, thereby enabling the problem to be resolved at an early stage.

In Performance Management, the operation that is to be taken when a specified threshold value is reached is called an *action*. The following types of actions can be set:

- Sending an email
- Executing a command
- Issuing an SNMP trap
- Issuing a JPI event

Defining a threshold together with an action constitutes an *alarm*. You use PFM - Web Console to set the alarms for the various type of performance data. For details about how to set alarms, see the chapter that describes operation monitoring by alarms in the *JPI/Performance Management User's Guide*.

When PFM - Web Console is used to set alarms, a table of the individual alarms is associated with PFM - RM for Platform. This table is called an *alarm table*; the association of an alarm table to PFM - RM for Platform is called *binding*.

Once an alarm table has been bound to PFM - RM for Platform, then whenever an item of performance data collected by PFM - RM for Platform reaches a threshold defined as an alarm, the defined action is executed.

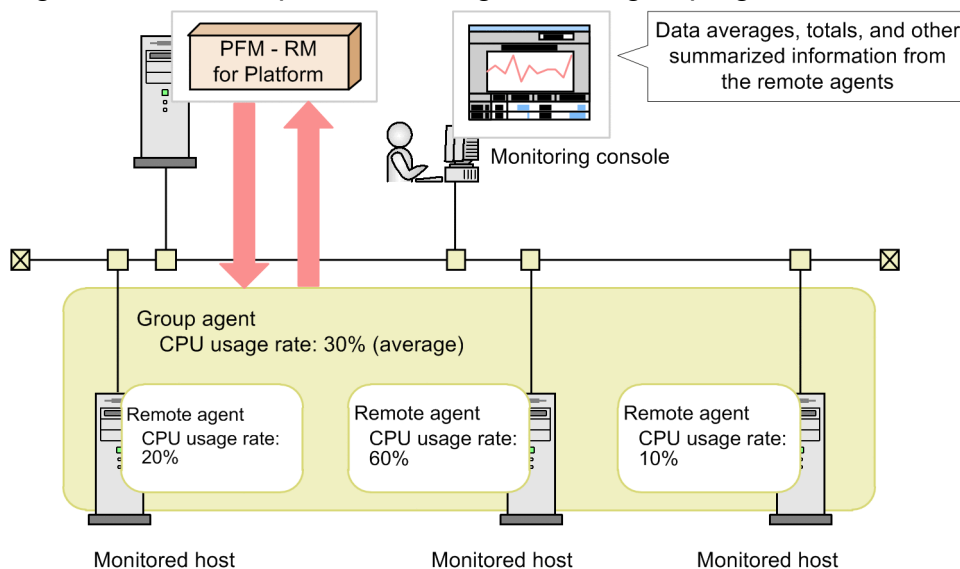

1.2.5 Integrating monitoring and analysis of performance data for multiple monitored hosts

PFM - RM for Platform can not only monitor and analyze performance data for each monitored host, but it can also monitor and analyze the performance data for all monitored hosts in an integrated manner.

PFM - RM for Platform treats each monitored host as a *remote agent*; the integration of remote agents is called a *group agent*.

The following figure shows the concept of remote agents and group agents.

Figure 1–2: Concept of remote agents and group agents

Legend:

 and  : Concept in Performance Management

 : Monitoring and collecting data

The information that is collected as a group agent includes performance data values for multiple monitored hosts, such as averages, totals, maximums, and minimums.

The remote agents that can be integrated as a group agent must belong to the same instance. Therefore, to integrate performance data, you must set the applicable monitored hosts in the same instance environment. For example, if you set instances as described below, you can visually analyze information for all the integrated monitored hosts:

- Setting, in the same instance, multiple guest OSs running in a virtual environment
- Setting, in the same instance, multiple servers that are operated for load distribution purposes

For details about remote agents and group agents, see the chapter that describes management of PFM - RM agents in the *JP1/Performance Management Planning and Configuration Guide*.

1.2.6 Easy setting of alarms and reports

In order to use reports and alarms and to analyze and obtain the operation status and trends of hosts, you must first define the required monitoring items. In Performance Management, this definition is called a *monitoring template*, and it is provided by PFM - RM for Platform.

A monitoring template enables you to easily prepare for monitoring of the operation status of monitored hosts without having to create complex definitions. For details about the monitoring template, see [6. Monitoring Template](#).

1.2.7 Applicable to cluster systems

You can also use PFM - RM for Platform in a cluster system.

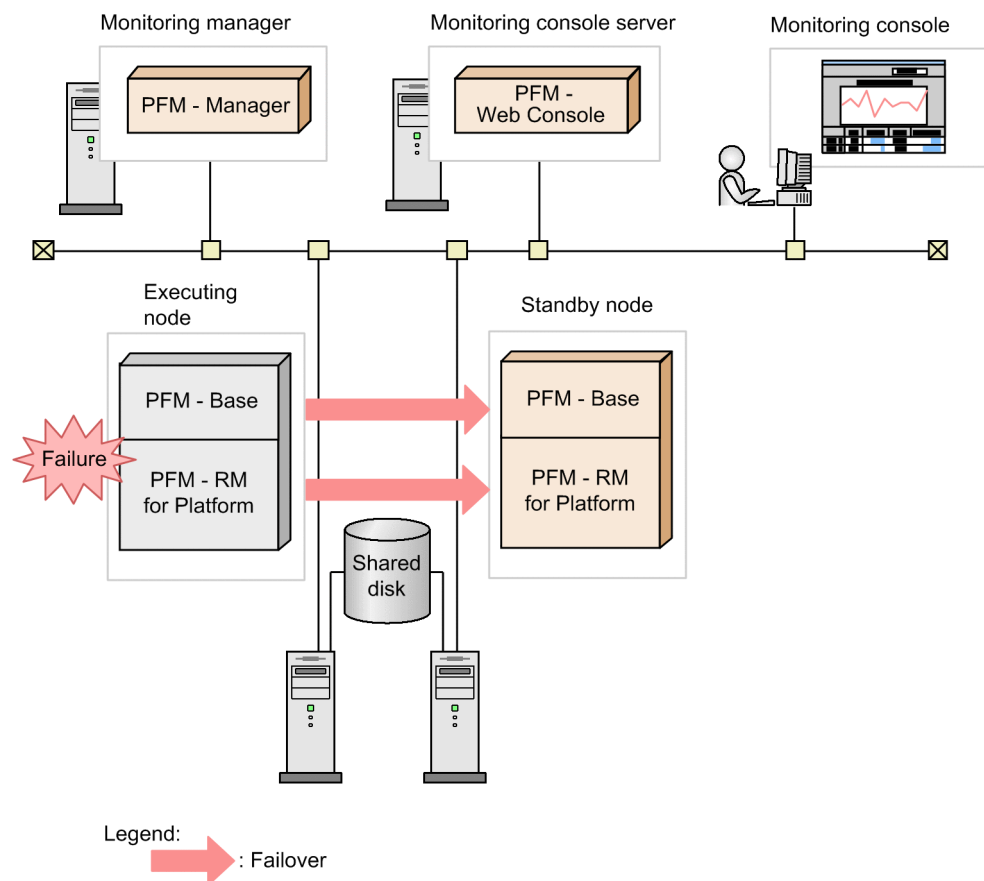

A cluster system links multiple server systems so that they can be run collectively as a single system.

You can run PFM - RM for Platform with a High Availability (HA) cluster system configuration.

Use of a cluster system enables you to configure a highly reliable system that is able to continue to operate, even in the event of a system problem. This enables you to achieve 24-hour/day operation and monitoring by Performance Management.

The following figure shows an example of the operation of Performance Management in the event of a problem on a monitored host in a cluster system.

Figure 1–3: Example of operation in the event of a problem on a monitored host in a cluster system

This example configures two environments with the same settings. It includes an *executing node* as the host used for normal operation and a *standby node* as the host used in the event of a failure.

For details about PFM - RM for Platform operation in a cluster system, see [5. Operation in a Cluster System](#).

2

Functions of PFM - RM for Platform

This chapter explains the functions of PFM - RM for Platform.

2.1 Collecting and managing performance data

This section describes the collection and management of performance data.

The performance data collected by PFM - RM for Platform is stored in records of either the PI record type or the PD record type, depending on the characteristics of the data to be collected.

The record type determines the collection and management methods, such as when performance data is collected and whether the performance data is stored in the Store database. For details about the collection and management methods for each record type, see the chapter that describes the Performance Management functions in the *JPI/Performance Management Planning and Configuration Guide*.

You use PFM - Web Console to set the performance data management methods. For details about setting the methods, see the chapter that describes management of operation monitoring data in the *JPI/Performance Management User's Guide*.

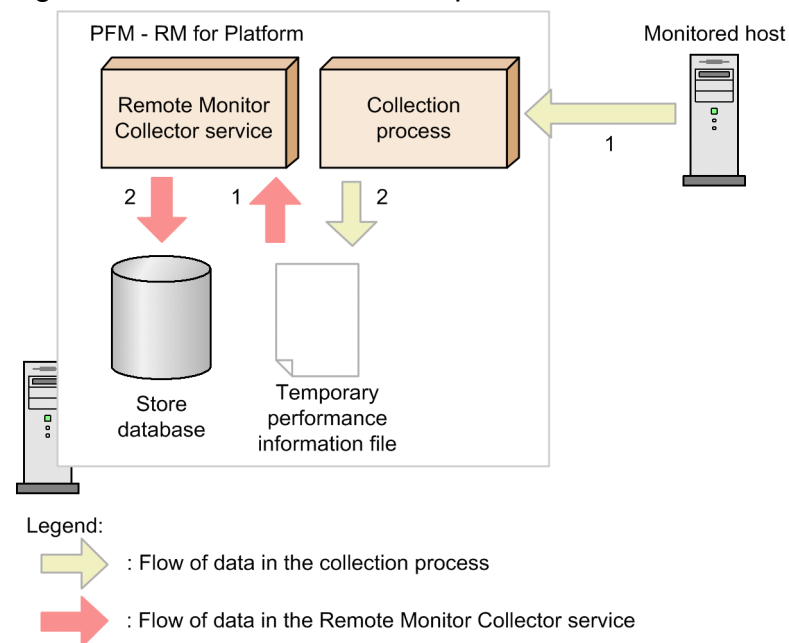

2.1.1 Flow of performance data collection

This subsection explains the flow of data and processing when PFM - RM for Platform collects performance data.

(1) Flow of data during performance data collection

The following figure shows the flow of data when performance data is collected.

Figure 2–1: Flow of data when performance data is collected

- Flow of data in the collection process
 1. Connects to the monitored host and collects its performance data.
 2. Outputs the collected performance data to the temporary performance information file.
- Flow of data in the Remote Monitor Collector service
 1. Loads the temporary performance information file that was output by the collection process.

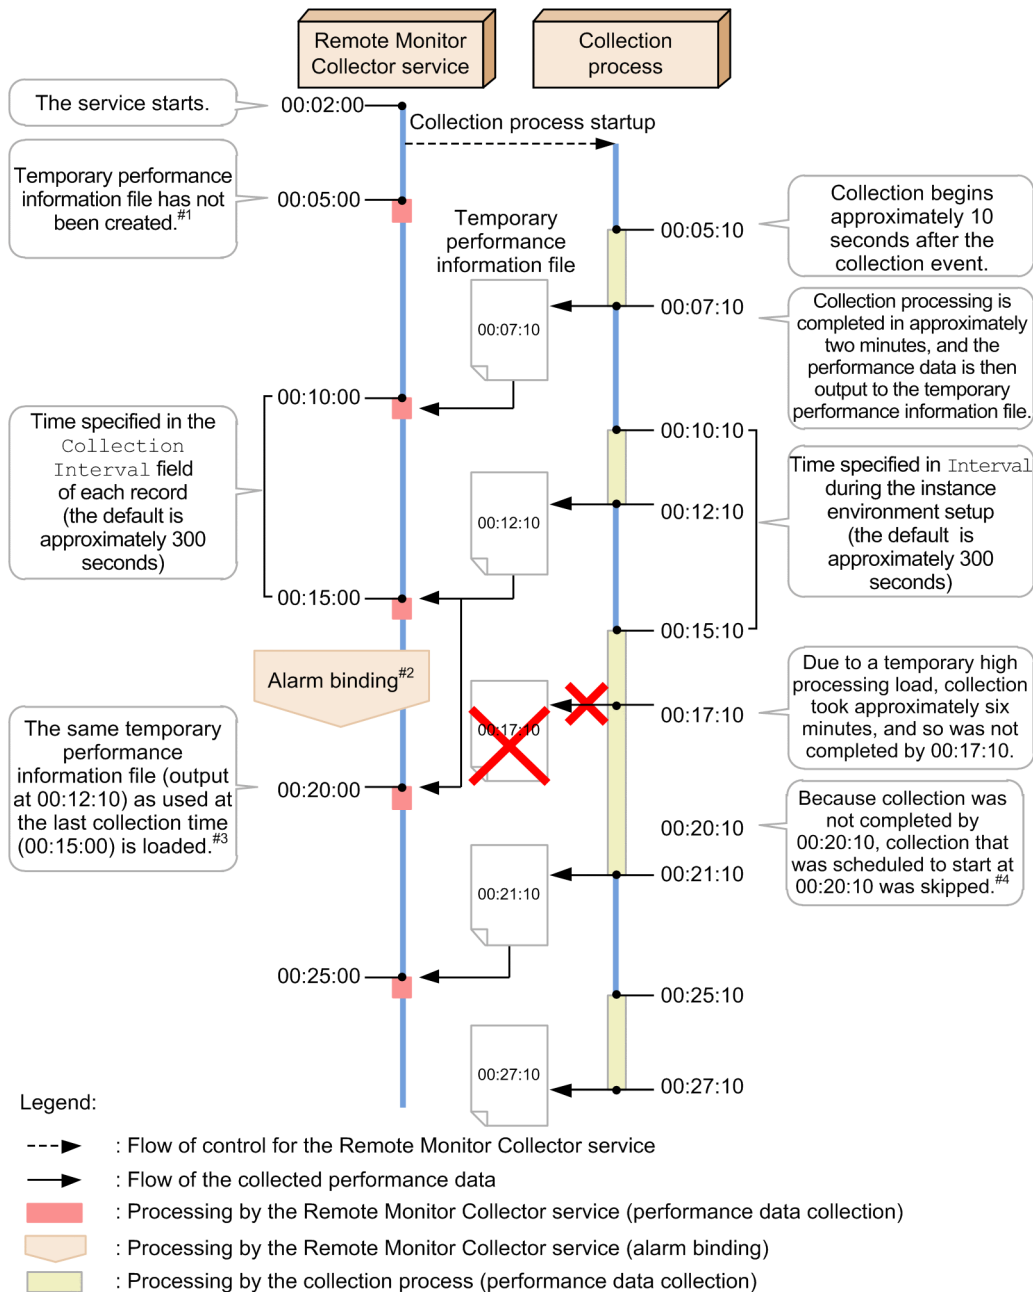

2. Stores the loaded performance data as records in the Store database.

The Remote Monitor Collector service and the collection processes operate separately, each on its own schedule.

(2) Flow of processing during performance data collection

The following figure shows an example of the flow of processing when performance data is collected.

Figure 2–2: Flow of processing when performance data is collected

#1

Because a temporary performance information file has not been created, data is not collected by collection processing at 00:05:00. The message KAVL17017-W is displayed.

#2

Consider the case when an alarm is bound between 00:15:00 and 00:20:00 during collection processing. This alarm might be evaluated at the 00:20:00 collection processing event (which is the first collection processing event after the alarm is bound). This depends on whether log information was collected in the record the alarm was bound to.

- The alarm is not evaluated if log information was collected.
- The alarm is evaluated if log information was not collected.

#3

As with collection processing at 00:15:00, the temporary performance information file output at 00:12:10 is loaded at the 00:20:00 collection processing.

If log information is being collected or if an alarm is to be evaluated, no performance data is collected. The message KAVL17016-W is displayed.

For collection processing based on real-time reports, the content of the temporary performance information file that was output at 00:12:10 is displayed, as was done at 00:15:00 of collection processing.

#4

Because the collection processing that started at 00:15:10 was not completed by 00:20:10, the collection processing that was scheduled to start at 00:20:10 is skipped.

Note

- When log information is stored in the Store database as performance data, the content being collected was actually created before the time of storage. The approximate time it takes from the collection of performance data to its storage in the Store database is at most the time specified in `Interval` during the instance environment setup (the default is approximately 300 seconds).
- The real-time report displays the content of the temporary performance information file that is in effect at the time the display operation is executed. If you refresh PFM - Web Console while a real-time report is being displayed, the content of the temporary performance information file that is in effect when you refreshed PFM - Web Console is displayed.
- Depending on the number of monitored hosts and the amount of data being collected, collection processing might lag.
- When you evaluate an alarm, the evaluation is performed on the performance data that was collected before the evaluation time. The approximate time it takes from the collection of performance data to the evaluation of an alarm is at most the time specified in `Interval` during the instance environment setup (the default is approximately 300 seconds).

If you bind an alarm that uses a record that has not collected log information, the evaluation might be performed on the performance data that was collected farther back in the past depending on factors such as the timing of alarm binding and the lag in collection processing.

2.2 How to monitor performance

This section describes how to monitor performance.

Performance Management monitors the system operation status using baseline values as threshold values. The *baseline* is the performance data values that are assumed to be free of problems for system operation. Before you start monitoring performance, you must select a baseline on the basis of measurement results.

You should select an appropriate baseline by measuring system performance as follows:

- Measure system performance when the system is operating at peak status.
We recommend that you select the baseline by measuring system performance when there are heavy loads in the operating environment.
- When you change system resources or the operating environment, measure the baseline again.
The baseline might be affected significantly by the system configuration. When you change the system configuration, you should measure the baseline again.

The subsections below present examples of monitoring the performance of the following system resources:

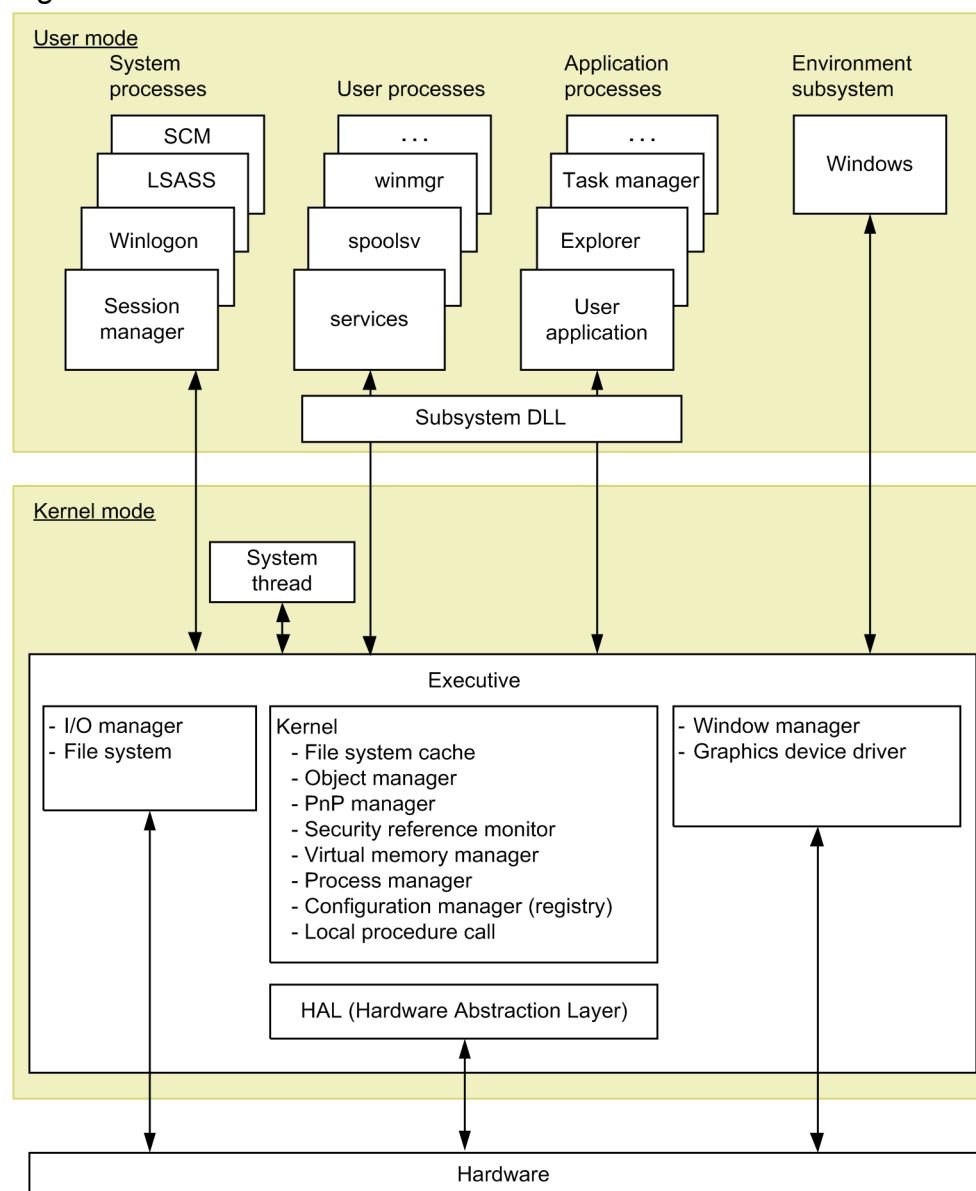

- Processor
- Memory
- Disk
- Network

2.2.1 Example of monitoring a processor

By monitoring processes, you can determine performance trends over the entire system.

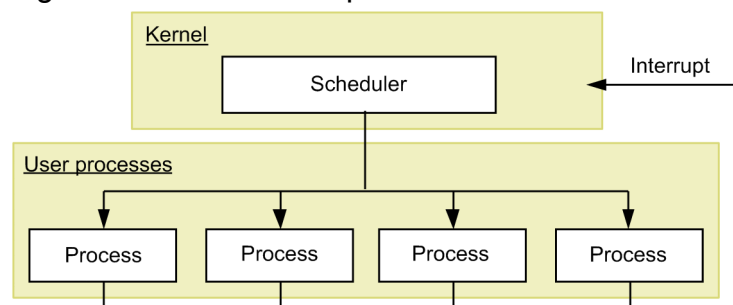

Windows processes consist of two types of processor access modes, called the user mode and the kernel mode. The following figure provides an overview of the Windows architecture.

Figure 2–3: Overview of the Windows architecture

UNIX processes consist of operations by kernel processes and operations by user processes. The following figure shows the relationship between the UNIX kernel and processes.

Figure 2–4: Relationship between the UNIX kernel and processes

(1) Overview of processor monitoring

Execution of jobs such as processes involves scheduling by the OS and allocation to the CPU. The queue request count that indicates the number of jobs waiting for CPU allocation tends to be proportional to the volume of loading in the entire system. Therefore, in general, you can obtain the processor usage status by monitoring the CPU usage rate and queue request count.

The following table lists and describes the records and fields that are used by PFM - RM for Platform for monitoring the processor.

Table 2–1: Records and fields used for processor monitoring

No.	Record	Field	Description of value	Interpretation of value
1	PI	Processor Queue Length	Queue request count	When this value continuously exceeds the threshold value, the processor might be busy.
2		Run Queue Avg 5 min	Average number of threads waiting in the execution queue	When this value is large, there might be a problem with processor utilization efficiency.
3		CPU %	CPU usage rate	When this value continuously exceeds the threshold value, the processor might be responsible for a system bottleneck.
4		System %	CPU usage rate in the kernel mode	When this value is large and the CPU % field of the PI record continuously exceeds the threshold value, there might be problems in a specific application process, such as a service or a system process.
5		User %	CPU usage rate in the user mode	When this value is large and the CPU % field of the PI record continuously exceeds the threshold value, there might be problems in a specific application process, such as a service.
6		Idle %	CPU idle rate	When this value is high, there might be no load on the CPU.
7		Interrupt Counts/sec	Hardware interrupt count (per second)	When the value of this field has increased greatly while the system workload is light, there might be a hardware interrupt problem, such as a slow device resulting in processor overloading.
8	PI_CPU#	CPU %	A processor's CPU usage rate	When this value continuously exceeds the threshold value, the processor might be responsible for a system bottleneck.
9		System %	CPU usage rate for a processor executed in the kernel mode	When this value is large and the CPU % field of the PI_CPU record continuously exceeds the threshold value, there might be problems in a specific application process, such as a service or a system process.
10		User %	CPU usage rate for a processor executed in the user mode	When this value is large and the CPU % field of the PI record continuously exceeds the threshold value, there might be problems in a specific application process, such as a service.
11		Interrupt Counts/sec	Hardware interrupt count (per second) for a processor	When the value of this field has increased greatly while the system workload is light, there might be a hardware interrupt problem, such as a slow device resulting in processor overloading.

#

Each field of the PI_CPU record is used to monitor the performance of one processor.

In a multiprocessor environment, the average value of all CPU usage rates is treated as the CPU usage rate for the system. Therefore, to obtain an accurate CPU usage rate, check the value for each CPU. To identify a process causing a bottleneck, check the CPU usage rate for each process.

You must use PFM - Agent for Platform to check the CPU usage rate for each process. For details about how to monitor processes, see the manual *JP1/Performance Management - Agent Option for Platform* (for Windows systems), or *JP1/Performance Management - Agent Option for Platform* (for UNIX systems).

(2) Example of a monitoring template for monitoring a processor

This subsection describes an example of alarms and reports that are provided as a monitoring template for monitoring a processor.

PFM - RM for Platform provides alarms and reports, such as the CPU Usage alarm and the CPU Used Status (Multi-Agent) report. To obtain more detailed performance information for a processor, you must monitor various aspects of the processor.

(a) Alarms

The following table lists and describes the processor-related alarms.

Table 2–2: Examples of alarms related to processor monitoring

No.	Alarm	Record	Field	Abnormal condition	Warning condition	Interpretation of value
1	CPU Usage	PI	CPU %	≥ 90	≥ 80	<p>A processor usage rate of 80% or higher is treated as the warning or abnormal status.</p> <p>When this value becomes greater than the threshold value set in the warning or abnormal condition, the process might be causing a system bottleneck.</p> <p>If you find a process that makes excessive use of the processor, you must check the status of the process, and then take appropriate action. If there is no process that is using the processor excessively, you might need to consider upgrading the processor or adding a new processor.</p>
2	Kernel CPU	PI	System %	> 75	> 50	<p>A CPU usage rate in the kernel mode of higher than 50% is treated as the warning or abnormal status.</p> <p>When this value becomes greater than the threshold value set in the warning or abnormal condition, there might be a problem in the OS or system operating procedures.</p> <p>Check to see if more processes than the kernel scheduling can overcome have been created or deleted in a short period of time, or if there is a process that uses the processor excessively, and then take appropriate action.</p> <p>If there is no process that is using the processor excessively, you might need to consider upgrading the processor or adding a new processor.</p>

No.	Alarm	Record	Field	Abnormal condition	Warning condition	Interpretation of value
3	Processor Queue	PI	Processor Queue Length	≥ 10	≥ 2	<p>A consecutive queue request count of 2 or greater is treated as the warning or abnormal status.</p> <p>When this value becomes greater than the threshold value set in the warning or abnormal condition, the process might be causing a system bottleneck.</p> <p>If you find a process that makes excessive use of the processor, you must check the status of the process and take appropriate action. If there is no process that is using the processor excessively, you might need to consider upgrading the processor or adding a new processor.</p>
4	Run Queue	PI	Run Queue Avg 5 min	> 8	> 4	<p>An average thread count greater than 4 in the execution queue is treated as the warning or abnormal status.</p> <p>When this value becomes greater than the threshold value set in the warning or abnormal condition, there might be a problem in the OS or system operating procedures or with a specific application.</p> <p>Check to see if more processes than the kernel scheduling can overcome have been created or deleted in a short period of time, or if there is a process that uses the processor excessively, and then take appropriate action.</p> <p>If there is no process that is using the processor excessively, you might need to consider upgrading the processor or adding a new processor.</p>
5	User CPU	PI	User %	> 85	> 65	<p>A CPU usage rate higher than 65% in the user mode is treated as the warning or abnormal status.</p> <p>When this value becomes greater than the threshold value set in the warning or abnormal condition, there might be a problem with a specific application.</p> <p>Check to see if more processes than the kernel scheduling can overcome have been created or deleted in a short period of time, or if there is a process that uses the processor excessively, and then take appropriate action.</p> <p>If there is no process that is using the processor excessively, you might need to consider upgrading the processor or adding a new processor.</p>

(b) Reports

The following table lists and describes the processor-related reports.

Table 2–3: Examples of reports related to processor monitoring

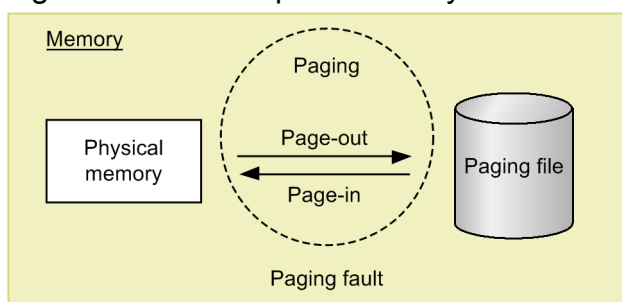

No.	Report name	Information displayed in the report
1	CPU Used Status (Multi-Agent)	Displays the CPU usage status in multiple systems.
2	CPU Used Status	Displays the CPU usage status in the system.
3	CPU Per Processor Status	Displays the processor usage status for each processor.

2.2.2 Example of monitoring memory

By monitoring memory, you can detect a shortage of physical memory or illegal operations by processes.

In Windows, memory consists of a physical memory and a paging file. The following figure shows the concept of memory in Windows.

Figure 2–5: Concept of memory in Windows

In UNIX, memory consists of a physical memory and a swap file. The following figure shows the concept of memory in UNIX.

Figure 2–6: Concept of memory in UNIX

(1) Overview of memory monitoring

In general, if there is a memory shortage in the physical memory and paging file (swap file), which use physical areas in RAM, the entire system's performance is affected adversely. However, a memory shortage alone is not always the cause of a bottleneck in the system.

Of the large amount of memory referenced by programs, the areas that are not accessed for more than a specific amount of time are saved in the paging file and loaded into the physical memory as needed. Because the speed of accessing this paging file (swap file) is much lower than the speed of accessing the physical memory, the efficiency of memory utilization is compromised.

Therefore, paging and page faults can be the cause of impaired system processing speed.

- *Paging and swapping*

Paging and swapping refer to the movement of codes and data between the physical memory and the paging file (swap file). Loading data from the paging file (swap file) into the physical memory is called *page-in*, and saving data from the physical memory into the paging file (swap file) is called *page-out*.

- *Page faults*

Page faults refers to accessing an area that does not exist in the physical memory.

We recommend that you monitor the efficiency of memory utilization, such as paging and page faults, as well as the memory usage. Note that paging occurs even during normal processing. Measure the baseline during stable system operation to determine an appropriate threshold value.

The following table lists and describes the records and fields that are used for monitoring the memory.

Table 2–4: Records and fields used for monitoring the memory

No.	Record	Field	Description of value	Interpretation of value
1	PI	Paging Pages/sec	Paging count (per second)	When the threshold value is exceeded continuously, the memory might be causing a system bottleneck due to frequent paging. Exceeding the threshold value temporarily is acceptable.
2		Page Fault Counts/sec	Number of page faults (per second)	When the threshold value is exceeded continuously, the memory might be causing a system bottleneck due to frequent page faults.
3		Total Mem Mbytes	Capacity of physical memory	Check the capacity of the physical memory.
4		Free Mem Mbytes	Free physical memory capacity	Check the free physical memory space.
5		Used Mem Mbytes	Amount of physical memory used	When this value is high, a large amount of physical memory might be in use.
6		Used Mem %	Physical memory usage rate	When this value is high, a large amount of physical memory might be in use.
7		Total Swap Mbytes	Capacity of virtual memory	Check the capacity of virtual memory.
8		Free Swap Mbytes	Free virtual memory capacity	Check the free virtual memory space.
9		Used Swap Mbytes	Amount of virtual memory used	When the threshold value is exceeded continuously, you might need a larger physical memory.
10		Used Swap %	Virtual memory usage rate	When the threshold value is exceeded continuously, you might need to expand the paging file.

A memory shortage can also occur due to defective programs.

Take appropriate action as necessary, such as identifying a process that unnecessarily uses a large amount of memory or whose memory usage increases continuously without limit, or monitor each process's memory usage.

You must use PFM - Agent for Platform to monitor each process's memory usage. For details about how to monitor processes, see the manual *JPI/Performance Management - Agent Option for Platform* (for Windows systems), or *JPI/Performance Management - Agent Option for Platform* (for UNIX systems).

(2) Example of a monitoring template for monitoring memory

This subsection describes an example of alarms and reports that are provided as a monitoring template for monitoring memory.

PFM - RM for Platform provides alarms and reports, such as the Available Memory alarm and the Memory Used Status (Multi-Agent) report. To obtain more detailed performance information for the memory, you must monitor various aspects of the memory.

(a) Alarms

The following table lists and describes the memory-related alarms.

Table 2–5: Examples of alarms related to memory monitoring

No.	Alarm	Record	Field	Abnormal condition	Warning condition	Interpretation of value
1	Available Memory	PI	Free Mem Mbytes	< 3	< 4	Free physical memory capacity below 4 is treated as the warning or abnormal status. When this value becomes smaller than the threshold value set in the warning or abnormal condition, a shortage of physical memory might have occurred. If you find a process that makes excessive use of the memory, you must check the status of the process, and then take appropriate action. If there is no process that is using the memory excessively, you must take an action such as expanding the memory.
2	Page Faults		Page Fault Counts/sec	>= 5	>= 4	A page fault count of 4 or greater per second is treated as the warning or abnormal status. When this value becomes greater than the threshold value set in the warning or abnormal condition, a memory shortage might have occurred.
3	Pagescans		Page Scan Counts/sec	> 150	> 100	A page scan count per second that exceeds 100 is treated as the warning or abnormal status. When this value becomes greater than the threshold value set in the warning or abnormal condition, a memory shortage might have occurred.
4	Swap Outs		Swapped-Out Pages/sec	> 200	> 100	If more than 100 pages are swapped out per second by swap-out processing, the system treats it as the warning or abnormal status. When this value becomes greater than the threshold value set in the warning or abnormal condition, a memory shortage might have occurred.
5	Used Swap Mbytes		Used Swap Mbytes	>= 1024 ^{#1}	>= 1024 ^{#2}	If the amount of virtual memory used exceeds the value of the Total Swap Mbytes field, the system treats it as the warning or abnormal status.

No.	Alarm	Record	Field	Abnormal condition	Warning condition	Interpretation of value
5	Used Swap Mbytes	PI	Used Swap Mbytes	≥ 1024 ^{#1}	≥ 1024 ^{#2}	When this value becomes greater than the threshold value set in the warning or abnormal condition, a memory shortage might have occurred.

#1

Set a value that is about 90% of the value of the Total Swap Mbytes field.

#2

Set the same value as for the Total Mem Mbytes field.

(b) Reports

The following table lists and describes the memory-related reports.

Table 2–6: Examples of reports related to memory monitoring

No.	Report name	Information displayed in the report
1	Memory Used Status (Multi-Agent)	Displays the status of physical memory usage in multiple systems.
2	Memory Used Status	Displays the status of physical memory usage in the system.
3	Pool Nonpaged Status	Displays the size of physical memory that cannot be paged out.
4	System Overview	Displays the operation status of the system.

2.2.3 Example of monitoring the disk

By monitoring the disk, you can detect a shortage of disk resources and identify a bottleneck caused by the disk. If you monitor the disk continuously, you can also identify trends in increasing disk usage, which can help you determine the system configuration and the timing of expansion.

(1) Overview of disk monitoring

The disk stores programs and the data used by the programs. If a shortage of free space occurs on the disk, not only does the system's response become slower but problems such as data loss also occur. A shortage of free disk space might also lead to other types of performance deterioration, such as a reduction in process response speed.

If there is not enough free disk space, a response wait status might occur when programs input data from the disk and output data to the disk. If the disk is suspected of being responsible for a bottleneck, such as because of a shortage of free disk space, first check if the disk has become fragmented. Next, check if an unreasonably large amount of disk space is being used by invalid files and if sufficient free space has been allocated.

The following table lists and describes the records and fields that are used for monitoring the disk.

Table 2–7: Records and fields used for disk monitoring

No.	Record	Field to be used	Description of value	Interpretation of value
1	PI_PDSK	Busy %	Disk busy rate	When the threshold value is exceeded continuously, there might be a concentration of processing that uses the disk.

No.	Record	Field to be used	Description of value	Interpretation of value
2	PI_PDSK	Avg Disk Time	Average disk I/O operation time	When the threshold value is exceeded continuously, there might be a concentration of processing that uses the disk.
3		Total MBytes/sec	Number of bytes transferred between disks (per second)	When this value is high, the system is considered to be running efficiently.
4	PI_LDSK	Free Mbytes %	Free disk space percentage	When this value is low, there might be a shortage of disk capacity.
5		Free Mbytes	Free disk space	When this value is low, there might be a shortage of disk capacity.

(2) Example of a monitoring template for monitoring the disk

This subsection describes examples of alarms and reports that are provided as a monitoring template for monitoring the disk.

PFM - RM for Platform provides alarms and reports, such as the Disk Busy % alarm and the Avg Disk Time Status report. To obtain more detailed performance of the disk, you must monitor various aspects of the disk.

(a) Alarms

The following table lists and describes the disk-related alarms.

Table 2–8: Examples of alarms related to disk monitoring

No.	Alarm	Record	Field	Abnormal condition	Warning condition	Interpretation of value
1	Disk Busy %	PI_PDSK	ID	<> _Total	<> _Total	A disk busy rate of 80% or higher is treated as the warning or abnormal status. When this value becomes greater than the threshold value set in the warning or abnormal condition, disk access might be busy.
2			Busy %	>= 90	>= 80	
3	Disk Service Time	PI_PDSK	Avg Disk Time	> 0.1	> 0.06	An average disk I/O operation that exceeds 0.06 second is treated as the warning or abnormal status. When this value becomes greater than the threshold value set in the warning or abnormal condition, a very large I/O operation might have occurred.
4	Disk Space	PI_LDSK	Free Mbytes %	< 5	< 15	A free disk space percentage rate that is less than 15% is treated as the warning or abnormal status. When this value becomes less than the threshold value set in the warning or abnormal condition, a shortage of free disk space might have occurred. You need to take an appropriate action, such as deleting unneeded files, compressing files, optimizing the disk, or expanding the disk.
5	I/O Wait Time	PI	Wait %	> 80	> 60	A disk I/O wait time that exceeds 60% is treated as the warning or abnormal status.

No.	Alarm	Record	Field	Abnormal condition	Warning condition	Interpretation of value
5	I/O Wait Time	PI	Wait %	> 80	> 60	When this value becomes greater than the threshold value set in the warning or abnormal condition, a delay in I/O operations might have occurred, such as a delay in database update processing.
6	Disk Free Size	PI_LDSK	ID	< _Total	< _Total	<p>Unused disk space of less than 10,240 megabytes is treated as the warning or abnormal status.</p> <p>When this value becomes less than the threshold value set in the warning or abnormal condition, a shortage of unused disk space might have occurred.</p> <p>You need to take an appropriate action, such as deleting unneeded files, compressing files, optimizing the disk, or expanding the disk.</p>
7			Free Mbytes	< 5120	< 10240	

(b) Reports

The following table lists and describes the disk-related reports.

Table 2–9: Examples of reports related to disk monitoring

No.	Report name	Information displayed in the report
1	Avg Disk Time Status	Displays the average I/O operation time for the physical disk.
2	Free Megabytes - Logical Disk	Displays information about the logical disk space being used.
3	Physical Disk Busy Status	Displays the percentage of time during which the disk was busy.

2.2.4 Example of monitoring the network

By monitoring network information, you can check the status of response speeds for system-provided functions. Also, continuous monitoring of the network, such as of the amount of data transfer in the network, can assist in evaluating the network configuration and planning for future expansion.

(1) Overview of network monitoring

Identifying a bottleneck in the network requires examination of various factors, such as hardware, client operations, and data transfer rates between servers and clients.

PFM - RM for Platform provides alarms and reports, such as the Network Received alarm and the Network Data report. To obtain more detailed information on network performance, you must monitor various aspects of the network.

The following table lists and describes the records and fields that are used for monitoring the network.

Table 2–10: Records and fields used for network monitoring

No.	Record	Field	Description of value	Interpretation of value
1	PI_NET	Total Bytes/sec	Amount of data transferred (per second)	If NIC is always used to transfer data and this value is often equal to or less than the threshold value, NIC might be causing the bottleneck. When this value is typically

No.	Record	Field	Description of value	Interpretation of value
1	PI_NET	Total Bytes/sec	Amount of data transferred (per second)	greater than the threshold value, a large amount data can be transferred successfully.
2		Rcvd Bytes/sec	Amount of data received (per second)	If NIC is always used to receive data and this value is often equal to or less than the threshold value, NIC might be causing the bottleneck. When this value is typically greater than the threshold value, a large amount data can be received successfully.
3		Sent Bytes/sec	Amount of data sent (per second)	If NIC is always used to send data and this value is often equal to or less than the threshold value, NIC might be causing the bottleneck. When this value is typically greater than the threshold value, a large amount data can be sent successfully.

(2) Example of a monitoring template for monitoring the network

This subsection describes an example of using the alarms and reports that are provided as a monitoring template for monitoring the network.

PFM - RM for Platform provides alarms and reports, such as the Network Received alarm and the Network Data report.

(a) Alarms

The following table lists and describes the network-related alarms.

Table 2–11: Examples of alarms related to network monitoring

No.	Alarm	Record	Field	Abnormal condition	Warning condition	Interpretation of value
1	Network Received	PI_NET	Rcvd Bytes/sec	≥ 50000 ^{#1}	≥ 50000 ^{#2}	When the amount of data received per second exceeds about 50% of the NIC bandwidth, the system treats it as the warning or abnormal status. When this value becomes greater than the threshold value set in the warning or abnormal condition, you need to take appropriate action, such as upgrading NIC or the physical network.

#1

Set a value that is about 70% of the NIC bandwidth.

#2

Set a value that is about 50% of the NIC bandwidth.

(b) Reports

The following table lists and describes the network-related reports.

Table 2–12: Examples of reports related to network monitoring

No.	Report name	Information displayed in the report
1	Network Data	Displays the status of communication between networks.

2.2.5 Example of monitoring processes and services

By monitoring processes and services, you can check whether the system is running normally.

(1) Overview of process and service monitoring

A system functions based on individual processes and services. Therefore, knowing the operating statuses of these processes and services is essential for stable system operation.

If the processes or services that provide the system's functionality terminate abnormally, the system will stop, resulting in serious adverse effects on operations. Therefore, it is important to monitor the initiation, termination, and startup status of processes and services, and to detect any errors quickly so that you develop corrective measures.

Using PFM - RM for Platform, you can collect the process operation status information from multiple monitored hosts and monitor it from PFM - Web Console. You specify the collection of process operation status information interactively using PFM - Web Console or by using commands.

PFM - RM for Platform monitors processes by collecting information from them. Therefore, note that even when processes and services are being monitored, their statuses are only reported when PFM - RM for Platform collects information from them, and not when their statuses actually change.

If collection processing that uses WMI or SSH is treated as a separate process (a core collection process) and this core collection process does not terminate within the specified time, performance information cannot be collected from a monitored target having the same instance for which collection has not been completed. A time-out occurs.

The following table lists and describes the records and fields that are used for monitoring the processes and services.

Table 2–13: Records and fields used for monitoring processes and services

No.	Record	Field to be used	Description of value	Interpretation of value
1	PD_APP2	Application Exist	Status of the application specified as a monitoring target	If this value is <code>ABNORMAL</code> , either all processes and services being monitored on a per-application basis are stopped, or more processes and services than necessary are running.
2		Application Status	Status of the application specified as a monitoring target	
3	PD_APS	Command Line	Command line for executing programs	If no records have been collected, the process might be stopped.
4		Program Name	Program name	
5	PD_ASVC	Display Name	Name used by the user interface program to identify a service	In all cases except when the application service (process) is running, the service might be stopped.
6		Service Name	Name of the service being used by the service control manager database	
7		State	Status of a service when data is being collected	

You can use PFM - RM for Platform to collect process operation status information by using one of the following methods:

- Collecting the status on a per-process or per-service basis

- Collecting the status on a per-application basis by grouping multiple processes or services

The following table shows the records used for each of these methods.

Table 2–14: Records used for collecting process operation status information (on a per-process or per-service basis)

No.	Record	Monitoring target	Information to be stored	Collection method
1	PD_APS	Processes in a Windows or UNIX environment	Stores performance data indicating the status of the monitored host's process at a given time.	Real-time
2	PD_ASVC	Services in a Windows environment	Stores performance data indicating the status of an application service registered in the monitored host's service control manager (SCM), such as a Win32 process.	Real-time

Table 2–15: Records used for collecting process operation status information (on a per-application basis)

No.	Record	Monitoring target	Information to be stored	Collection method
1	PD_APP2	<ul style="list-style-type: none"> Processes in a Windows or UNIX environment Services in a Windows environment 	Stores performance data that summarizes the records stored in the Application Process Overview (PD_APS) or Application Service Overview (PD_ASVC) record in the status, at a given point in time, on a per-application basis.	<ul style="list-style-type: none"> Real-time History
2	PD_APPC		Stores as performance data the records stored in the Application Process Overview (PD_APS) or Application Service Overview (PD_ASVC) record in the status, at a given point in time, on each process and service being monitored, on a per-application basis.	
3	PD_APPD		Stores performance data that summarizes the records stored in the Application Process Overview (PD_APS) or Application Service Overview (PD_ASVC) record in the status, at a given point in time, on each process and service being monitored, on a per-application basis. This stored performance data is more detailed than the Application Process Count (PD_APPC) records.	Real-time

The relationships between the process name, program name, program path, and command line used for setting up process status monitoring are explained below using examples.

When the monitored host is Windows

When the monitored host is UNIX

(2) Usage example of templates related to monitoring of processes and services

This subsection shows a usage examples of alarms and reports, which are provided as monitoring templates, related to process and service monitoring.

PFM - RM for Platform provides templates such as the Process Existence alarm and the Application Status report.

(a) Alarms

The following table lists and describes alarms related to monitoring of process and service statuses.

Table 2–16: Usage examples of alarms related to monitoring of process and service statuses

No.	Alarm	Record used	Field used	Error condition	Warning condition	Interpretation of value
1	Application Status	PD_APP2	Application Exist	Application Name = * AND	Application Name = * AND	Either one of the processes or services being monitored on a per-application basis is stopped, or more processes and services than necessary are running.
2			Application Name	Application Exist =	Application Exist = NORMAL	
3			Application Status	ABNORMAL AND Application Status = ABNORMAL	AND Application Status = ABNORMAL	
4	Process Existence	PD_APS	Program Name	Program Name <> jpcsto.exe ^{#1}	Program Name <> jpcsto.exe ^{#1}	If no records have been collected, a warning or error state has occurred.
5	Service Stop	PD_ASVC	Service Name State	Service Name = JP1PCAGT_7S ^{#2} AND State <> Running	Service Name = JP1PCAGT_7S ^{#2} AND State <> Running	If the monitoring-target service has not started, a warning or error state has occurred.
6	Service Stop(dsp nm)	PD_ASVC	Display Name State	Display Name = PFM - Remote Monitor for Platform ^{#3} AND State <> Running	Display Name = PFM - Remote Monitor for Platform ^{#3} AND State <> Running	If the monitoring-target service has not started, a warning or error state has occurred.

#1

Specify the name of the program to be monitored.

#2

Specify the name of the service to be monitored.

#3

Specify the display name of the service to be monitored.

(b) Reports

The following table lists and describes the reports related to monitoring of process and service statuses.

Table 2–17: Usage examples of reports related to monitoring of process and service statuses

No.	Report name	Displayed content of the report
1	Application Process Count	Operating state of the processes or services being monitored on a per-application basis
2	Application Process Status	
3	Application Status	Operating state of an application

3

Installation and Setup

This chapter explains how to install and set up PFM - RM for Platform. For details about how to install and set up the entire Performance Management system, see the chapter that describes installation and setup in the *JP1/Performance Management Planning and Configuration Guide*.

3.1 Installation and setup of the Windows edition

This section describes the procedures for installing and setting up PFM - RM for Platform in a Windows environment.

3.1.1 Issues to consider before installing the Windows edition

This subsection describes issues to be considered before you install PFM - RM for Platform.

(1) Prerequisite OS

PFM - RM for Platform can run on the following operating system (OS):

- Windows Server 2008
- Windows Server 2012
- Windows Server 2016

(2) Setting up a network environment

To use Performance Management to run PFM - RM for Platform, you must set up a network environment, such IP addresses and port numbers.

(a) Setting IP addresses

You must set up the environment for PFM - RM for Platform in such a way that it can resolve an IP address from a host name. PFM - RM for Platform will not start in an environment in which an IP addresses cannot be resolved.

In Performance Management, a host such as a PFM - RM for Platform host that is used in the Performance Management system is called a *monitoring host*.

You use one of the following methods to set host names and IP addresses:

- `jpchosts` file (Performance Management's host information configuration file)
- `hosts` file
- DNS

For the monitoring host name, use either the real host name or the alias name.

- Using the real host name

In a Windows environment, specify the name in such a way that the IP address can be resolved from a host name that can be checked with the execution results of the `hostname` command.

Note that Performance Management supports DNS, but not FQDN. This means that when you set the IP address, you must use the host name obtained by the `hostname` command without the domain name.

- Using an alias name

Set up the environment in such a way that the IP address can be resolved from a specified alias name.

For details about setting the name of the monitoring host, see the chapter that describes installation and setup in the *JP1/Performance Management Planning and Configuration Guide*.

Note that the IP address specified in the `jpchosts` file is not used for IP address resolution with the monitored host.

Notes about setting IP addresses

- If you use Performance Management in multiple LAN environments, use the `jpchosts` file to set IP addresses. For details about using the `jpchosts` file to set IP addresses, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.
- Performance Management will not run on a host where IP addresses are assigned dynamically by DHCP. You must set fixed IP addresses for all monitoring hosts.

(b) Settings for using IPv6

Performance Management supports both IPv4 and IPv6 network environments. Therefore, you can run Performance Management even in a network environment where IPv4 and IPv6 coexist.

PFM - RM for Platform can use IPv6 to communicate with PFM - Manager. However, this applies only when the OS of the host on which PFM - RM for Platform and PFM - Manager are installed is Windows or Linux. For details about the applicable scope of communication in the IPv4 and IPv6 environments, see [L. Communication in IPv4 and IPv6 Environments](#).

To communicate using IPv6, you must enable the use of IPv6 on both the PFM - Manager host and the PFM - RM host. Before installing PFM - RM for Platform, you must also enable the use of IPv6 on the PFM - RM host. To configure this setting, execute the `jpccconf ipv6 enable` command. If the use of IPv6 is already enabled, there is no need to configure this setting. To check whether the use of IPv6 is enabled, execute the `jpccconf ipv6 display` command.

For details about the `jpccconf ipv6 enable` and `jpccconf ipv6 display` commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*. For details about the conditions and timing for executing the `jpccconf ipv6 enable` command, see the chapter that describes an example of a network configuration that includes an IPv6 environment in the *JPI/Performance Management Planning and Configuration Guide*.

When PFM - RM for Platform will use IPv6 to communicate with monitored hosts, specify a monitored host name that can be resolved.

PFM - RM for Platform uses a resolvable IP address to communicate with a monitoring target. When PFM - RM for Platform communicates with a monitoring target in an environment where IPv4 and IPv6 coexist, PFM - RM for Platform will not try to communicate using another IP address if communication using a resolvable IP address fails.

For example, if a connection attempt using IPv4 fails, PFM - RM for Platform will not retry using IPv6. Similarly, if a connection attempt using IPv6 fails, PFM - RM for Platform will not retry using IPv4. Therefore, make sure that connection can be established before starting PFM - RM.

(c) Setting port numbers

You must assign a port number to each service of the programs used in Performance Management. Set up the network in such a manner that the port numbers assigned to PFM - RM for Platform can be used for communication.

The table below lists and describes the default port number assigned to various services. For other services, an unused port number is assigned automatically each time the service starts.

Table 3–1: Default port numbers for services (for Windows)

No.	Supported function	Service name	Parameter	Port number	Description
1	Service configuration information management function	Name Server	<code>jp1pcnsvr</code>	22285	Port number used by PFM - Manager's Name Server service.

No.	Supported function	Service name	Parameter	Port number	Description
1	Service configuration information management function	Name Server	jplpcnsvr	22285	This port number is set at all hosts of Performance Management.
2	Service status management function	Status Server	jplpcstatsvr	22350	Port number used by the Status Server service of PFM - Manager and PFM - Base. This port number is set at the host where PFM - Manager and PFM - Base are installed.
3	Monitoring console communication function	View Server	jplpcsvr	22286	Port number used by the View Server service of PFM - Manager. This port number is set at the host where PFM - Manager is installed.
4	Web service function	Web Service	--	20358	Port number used by the Web Service service of PFM - Web Console.
5	Web container function	Web Console	--	20359 20360	Port number used by the Web Console service of PFM - Web Console.
6	JP1/SLM linkage facility	JP1/ITSMLM	--	20905	Port number specified in JP1/SLM.

Legend:

--: Not applicable

When you use Performance Management in an environment that includes a firewall, you must use fixed port numbers. For details about how to use fixed port numbers, see the chapter that describes installation and setup in the *JP1/Performance Management Planning and Configuration Guide*.

(3) OS user permissions required for installation

When you install PFM - RM for Platform, make sure that you use an account that has Administrator permissions.

(4) Prerequisite programs

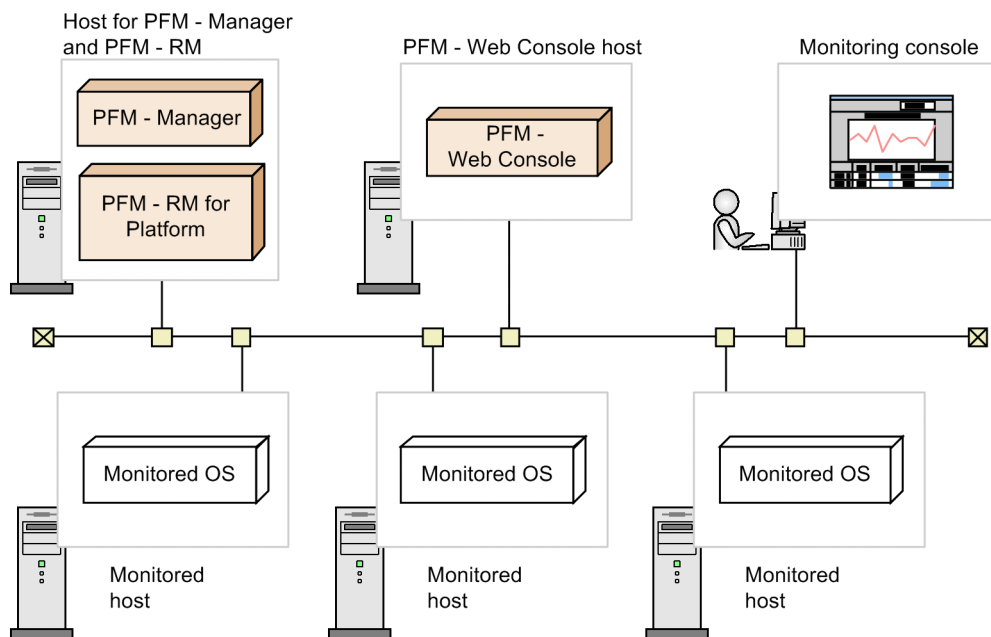

This subsection describes the configuration of programs required in order to install PFM - RM for Platform.

There are two major types of program configurations, as described below. Evaluate the program configurations from the perspective of your system environment.

(a) When installing PFM - RM for Platform on the PFM - Manager host

With this program configuration, PFM - RM for Platform is installed on the same host as PFM - Manager. The following figure shows the program configuration.

Figure 3–1: Program configuration (when PFM - RM for Platform and PFM - Manager are installed on the same host (for Windows))

Legend:

 : Program provided by Performance Management

 : Required program

(b) When installing PFM - RM for Platform on a host other than the PFM - Manager host

With this program configuration, PFM - RM for Platform is installed on a host other than the PFM - Manager host. If you use this program configuration, you must install PFM - Base on the same host as for PFM - RM for Platform. The following figure shows the program configuration.

Figure 3–2: Program configuration (when PFM - RM for Platform and PFM - Base are on the same host (for Windows))

(c) Prerequisite OSs for monitored hosts

A monitored host must be using one of the following OSs:

- Windows Server 2003
- Windows Server 2008
- Windows Server 2012
- Windows Server 2016
- HP-UX
- Solaris
- AIX
- Linux

Note that health check monitoring can monitor hosts and hardware equipment, even not running the prerequisite OSs listed above, that support the ICMP protocol (can communicate through `ping` command).

(d) Prerequisite programs for Performance Management

PFM - Manager or PFM - Base must be available on the host where PFM - RM for Platform is installed.

If you install PFM - RM for Platform on a host where PFM - Manager is available, PFM - Base is not required. If you install multiple PFM - RMs on a host where PFM - Base is available, you need only one PFM - Base.

You also need PFM - Web Console in order to use PFM - RM for Platform to monitor the operation of monitored hosts.

(5) Environment settings required for collecting performance data (when both the PFM - RM host and the monitored hosts are running Windows)

PFM - RM for Platform uses WMI to collect performance data from monitored hosts when these hosts are running Windows. Performance data cannot be collected if WMI connection settings have not been specified. Therefore, you must specify WMI settings at the PFM - RM host as well as at the monitored hosts.

The following describes the required WMI settings.

(a) Setting the user accounts

To use WMI, you need a local user account or domain account for the PFM - RM host, and a local user account for the monitored host.

PFM - RM for Platform collects information using the account that is specified for connection in WMI's name space.

- PFM - RM host account

To set up the host account, specify the values appropriate to the `RMHost_User`, `RMHost_Password`, and `RMHost_Domain` settings shown in [Table 3-10 Instance environment setting items and values for PFM - RM for Platform \(for Windows\)](#). You specify this account when you set up an instance.

If you run PFM - RM for Platform in a cluster system, set up the account for the PFM - RM host so that it is possible to log on to both the executing system and the standby system by specifying the same user name and password.

When the PFM - RM host itself is the monitoring target, the specified account also affects the WMI connection. The type of records that can be collected differs depending on the account type. The following table shows various account types and whether records can be collected.

Table 3–2: PFM - RM host account types and whether records can be collected (when the monitored host is the local host and is running Windows)

Account type	Can records be collected?	
	Records that stores process operation status information ^{#1}	Records that stores information other than process operation status ^{#2}
Administrator (Built-in Administrator)	Y	Y
Administrators group member (UAC enabled)	N	N
Administrators group member (UAC disabled)	Y	Y
Performance Log Users group member	N	Y
Performance Monitor Users group member	N	Y

Legend:

Y: Can be collected.

N: Cannot be collected.

#1

Applies to `PD_APS`, `PD_ASVC`, `PD_APP2`, `PD_APPC`, and `PD_APPD` records.

#2

Applies to `PI`, `PI_CPU`, `PI_LDSK`, `PI_NET`, `PI_PDSK`, and `PD` records.

- Monitored host accounts

To set up a monitored host account, specify the values appropriate to the `User`, `Password`, and `Domain` settings shown in [Table 3-17 Setting items and values for a monitored host in PFM - RM for Platform](#). You specify such an account when you set up each monitoring target.

Note that a monitored host account must be set as a member of the Administrators, Performance Log Users, or Performance Monitor Users group.

You need permissions to perform operations such as Windows security audits.

The type of records that can be collected differs depending on the account type. The following table shows various account types and whether records can be collected.

Table 3–3: Account types and whether records can be collected (when the monitored host is running Windows Server 2003)

Account type	Can records be collected?	
	Records that stores process operation status information ^{#1}	Records that stores information other than process operation status ^{#2}
Administrator (Built-in Administrator)	Y	Y
Administrators group member	Y	Y
Performance Log Users group member	N	Y
Performance Monitor Users group member	N	Y

Legend:

Y: Can be collected.

N: Cannot be collected.

#1

Applies to PD_APS, PD_ASVC, PD_APP2, PD_APPC, and PD_APPD records.

#2

Applies to PI, PI_CPU, PI_LDSK, PI_NET, PI_PDSK, and PD records.

Table 3–4: Account types and whether records can be collected (when the monitored host is running Windows Server 2008 or later)

Account type		Can records be collected?	
		Record that stores process operation status information ^{#1}	Record that stores information other than process operation status ^{#2}
Local account	Administrator (Built-in Administrator)	Y	Y
	Administrators group member (UAC enabled and LocalAccountTokenFilterPolicy not specified)	N	N
	Administrators group member (UAC enabled and LocalAccountTokenFilterPolicy specified)	Y	Y
	Administrators group member (Local host not monitored, UAC enabled, and LocalAccountTokenFilterPolicy specified)	Y	Y
	Performance Log Users group member	N	Y
	Performance Monitor Users group member	N	Y
Domain account	Administrator (Built-in Administrator)	Y	Y
	Administrators group member (UAC enabled)	Y	Y
	Administrators group member (UAC disabled)	Y	Y
	Performance Log Users group member	N	Y

Account type		Can records be collected?	
		Record that stores process operation status information ^{#1}	Record that stores information other than process operation status ^{#2}
Domain account	Performance Monitor Users group member	N	Y

Legend:

Y: Can be collected.

N: Cannot be collected.

#1

Applies to PD_APS, PD_ASVC, PD_APP2, PD_APPC, and PD_APPD records.

#2

Applies to PI, PI_CPU, PI_LDSK, PI_NET, PI_PDSK, and PD records.

(b) Setting the WMI service

Set the WMI service startup option for monitored hosts to a value other than **Disabled**. If it is set to **Disabled**, performance data will not be collected.

(c) WMI connection settings

Specify the WMI connection settings at both the PFM - RM host and the monitored hosts. For details about the WMI connection settings, see [3.1.5 WMI connection setting method \(when both the PFM - RM host and the monitored host are running Windows\)](#).

(d) Setting up WMI remote connection that uses UAC

In Windows, the UAC function restricts the permissions granted to local users who have Administrator permissions (except for the Administrator user who is created after OS installation). For details, see [3.1.5\(4\) Setting up UAC](#).

Consequently, if WMI remote connection to monitored servers running Windows Server 2008 or later is executed as a local user who has Administrator permissions, a problem might occur. That is, because the connection attempt will be made with ordinary user permissions instead of Administrator permissions, the access might be refused, resulting in an error. To avoid this, take one of the following steps if UCA is enabled:

- For the user to be used for authentication, use the Administrator user who is created during OS installation.
- Execute the following command with Administrator permissions to update the registry value to make UAC permit remote connection.

You can take this step only when the local host is not to be monitored.

```
reg add HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System /v LocalAccountTokenFilterPolicy /t REG_DWORD /d 1 /f
```

To cancel the remote connection permitted by UAC, execute the following command:

```
reg delete HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System /v LocalAccountTokenFilterPolicy /f
```

If UAC is disabled, use a member of the Administrator group as the user to be used for authentication. You must also take the following steps to set up local security policies:

1. Select **Control Panel, Administrative Tools**, and then **Local Security Policy**.
2. Select **Security Settings, Local Policies**, and then **Security Options**.

(6) Environment settings required for collecting performance data (when the PFM - RM host is running Windows and the monitored hosts are running UNIX)

PFM - RM for Platform uses SSH to collect performance data from monitored hosts when these hosts are running UNIX. To use SSH, you must install PuTTY and ActivePerl on the PFM - RM host. Performance data cannot be collected if SSH connection settings have not been specified. Because SSH authentication uses the public key authentication method, you must specify public key authentication settings. You might also need to install other appropriate software and packages on the PFM - RM host and the monitored hosts because OS commands are used to collect performance data.

Notes on installing PuTTY and ActivePerl

- To perform the installation, you must use an account that has Administrators permissions.
- Do not install into a folder whose path name includes a multi-byte character.

(a) User account settings

To use SSH, both PFM - RM host and monitored host accounts are required.

- **PFM - RM host account**

To set up an account, specify the values using the settings for `RMHost_User`, `RMHost_Password`, and `RMHost_Domain` in [Table 3-10 Instance environment setting items and values for PFM - RM for Platform \(for Windows\)](#). The account that is set up must be specified during instance setup.

If you run PFM - RM for Platform in a cluster system, specify the same user and password for the PFM - RM host account at both the active server and the standby server so that the account can log on to both servers.

- **Monitored host account**

If the OS of the connection-target monitored host is AIX and a user other than `root` user is to collect information, that user must belong to both the `adm` group and the `system` group; otherwise, some information will not be collected.

To ensure that the user belongs to both groups (`adm` and `system`), execute the following command at the connection-target monitored host:

```
$ id
uid=xxx(xxx) gid=x(xxx) groups=0(system),4(adm)
```

For details about the information that is not collected, see [7. Records](#). If the OS of the monitored host is not AIX, this user limitation is not applicable.

(b) Installing software and packages

■ Software required for the PFM - RM host

For details about the software required when the PFM - RM host is running Windows and the monitored host is running UNIX, see the *Release Notes* for this product.

■ Packages required for monitored hosts (SSH)

The set of packages (SSH) required for a monitored host depends on the OS of the monitored host. For details, see the *Release Notes* for this product.

■ Packages required for monitored hosts (commands)

You can determine which packages are required for a monitored host by executing the appropriate command shown in the following table.

Table 3–5: Commands for determining the required packages and file sets

No.	OS	Command execution format
1	HP-UX	<code>/usr/sbin/swlist -l file grep {command-name}</code>
2	Solaris 10	<code>/usr/sbin/pkgchk -l -p {command-name}</code>
3	Solaris 11 or later	<code>/usr/bin/pkg search -l -H -o pkg.name {command-name}</code>
4	AIX	<code>/usr/bin/lslpp -w {command-name}</code>
5	Linux	<code>/bin/rpm -q --whatprovides {command-name}</code>

The commands to be used and the packages are described below.

The following table lists the commands required for the records to be collected.

Table 3–6: Commands required for the records to be collected

No.	Record name	Command name			
		HP-UX	Solaris	AIX	Linux
1	<ul style="list-style-type: none"> Application Process Count (PD_APPC) Application Process Detail (PD_APPD) Application Process Overview (PD_APS) Application Service Overview (PD_ASVC) Application Summary (PD_APP2) 	<ul style="list-style-type: none"> date ps 	<ul style="list-style-type: none"> date ps 	<ul style="list-style-type: none"> date ps 	<ul style="list-style-type: none"> date ps
2	Logical Disk Overview (PI_LDSK)	<ul style="list-style-type: none"> date df 	<ul style="list-style-type: none"> date df 	<ul style="list-style-type: none"> date df 	<ul style="list-style-type: none"> date df
3	Network Interface Overview (PI_NET)	<ul style="list-style-type: none"> date netstat 	<ul style="list-style-type: none"> date netstat 	<ul style="list-style-type: none"> date netstat 	<ul style="list-style-type: none"> date netstat
4	Physical Disk Overview (PI_PDSK)	<ul style="list-style-type: none"> date iostat sar 	<ul style="list-style-type: none"> date iostat 	<ul style="list-style-type: none"> date sar 	<ul style="list-style-type: none"> date iostat
5	Processor Overview (PI_CPU)	<ul style="list-style-type: none"> date sar 	<ul style="list-style-type: none"> date mpstat 	<ul style="list-style-type: none"> date mpstat sar 	<ul style="list-style-type: none"> date mpstat
6	System Status (PD)	<ul style="list-style-type: none"> date uname 	<ul style="list-style-type: none"> date uname 	<ul style="list-style-type: none"> date uname 	<ul style="list-style-type: none"> date uname

No.	Record name	Command name			
		HP-UX	Solaris	AIX	Linux
7	System Summary (PI)	<ul style="list-style-type: none"> • crashconf • date • sar • swapinfo • uptime • vmstat 	<ul style="list-style-type: none"> • date • mpstat • prtconf • sar • swap • uptime • vmstat 	<ul style="list-style-type: none"> • date • mpstat • pstat • sar • uptime • vmstat 	<ul style="list-style-type: none"> • date • free • mpstat • sar • uptime • vmstat

For details about the packages required for collecting records, see the *Release Notes* for this product.

(c) SSH connection settings

Specify the SSH connection settings on both the PFM - RM host and the monitored hosts. For details about the SSH connection settings, see [3.1.6 SSH connection setting method for Windows \(when the PFM - RM host is running Windows and the monitored host is running UNIX\)](#).

(7) Environment settings required for monitoring the operating status (when health check monitoring is used)

To use health check monitoring, the health check function must be set up so that it can monitor the operating statuses of monitored hosts. The following describes the required health check monitoring settings.

(a) Setting the connection-target PFM - Manager

The health check function must be enabled on the connection-target PFM - Manager.

For details about the setting method of the health check function, see the chapter that describes the settings of the health check function in the *JP1/Performance Management User's Guide*.

(b) Setting at the PFM - RM host

The following settings must be enabled on the PFM - RM host:

- Status management function
For details about the setting method of the status management function, see the chapter that describes the settings of the status management function in the *JP1/Performance Management User's Guide*.
- Monitored host polling
Set the Health Check for Target Hosts property to Yes in the Remote Monitor Collector service of PFM - RM for Platform.

(c) Setting health check monitoring

Set the `TargetType` property for the PFM - RM for Platform remote agent to `icmp`. Health check monitoring can monitor the operating statuses of hosts and hardware equipment that support the ICMP protocol (can communicate through ping command).

For details about the settings of health check monitoring, see [3.1.4\(3\) Setting the monitored host](#).

(8) Prerequisite when setting the process operation monitoring condition to 4,096 bytes

When using version 10-00 or later of PFM - Manager and PFM - Web Console, you can set the monitoring condition to be used for monitoring performance to a maximum of 4,096 bytes.

When installing PFM - Base or PFM - Manager on the PFM - RM host, use version 10-00 or later.

(9) Preparing to collect information when an error occurs

When a problem occurs, you might have to collect information such as memory dumps and user-mode process dumps. If you want to collect these types of information when a problem occurs, enable the output of memory dumps and user-mode process dumps before starting PFM - RM.

(a) Memory dump output settings

1. From **Control Panel**, double-click **System**.
2. Under the **Advanced** tab, choose **Startup and Recovery**, and then click **Settings**.
3. Under **Write debugging information**, choose **Kernel memory dump**, and then specify an output destination file.

Note:

The memory dump size varies according to the size of the physical memory. If a large amount of physical memory is installed, the memory dump size will be large. Therefore, allocate a disk area that is large enough for collecting the memory dump. For details, see the documentation for the OS.

(b) Output settings for user-mode process dump

By entering the following registry, you can instantly collect user-mode process dump for investigation purposes if an application program terminates abnormally:

```
\HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\Windows Error Reporting  
\LocalDumps
```

Specify the following registry values in the registry key:

- DumpFolder : REG_EXPAND_SZ <dump-output-destination-folder-name>
(You must have permissions to write data to the output destination folder.)
- DumpCount : REG_DWORD <number-of-dumps-to-be-saved>
- DumpType : REG_DWORD 2

Note:

- Setting up this registry entry enables you to output user-mode process dumps in JP1 as well as other application programs. Be aware of this point when deciding to output user-mode process dump.
- When a user-mode process dump is output, it uses disk space. Therefore, when you decide to output user-mode process dump, make sure that sufficient disk space is allocated to the specified dump output destination folder.

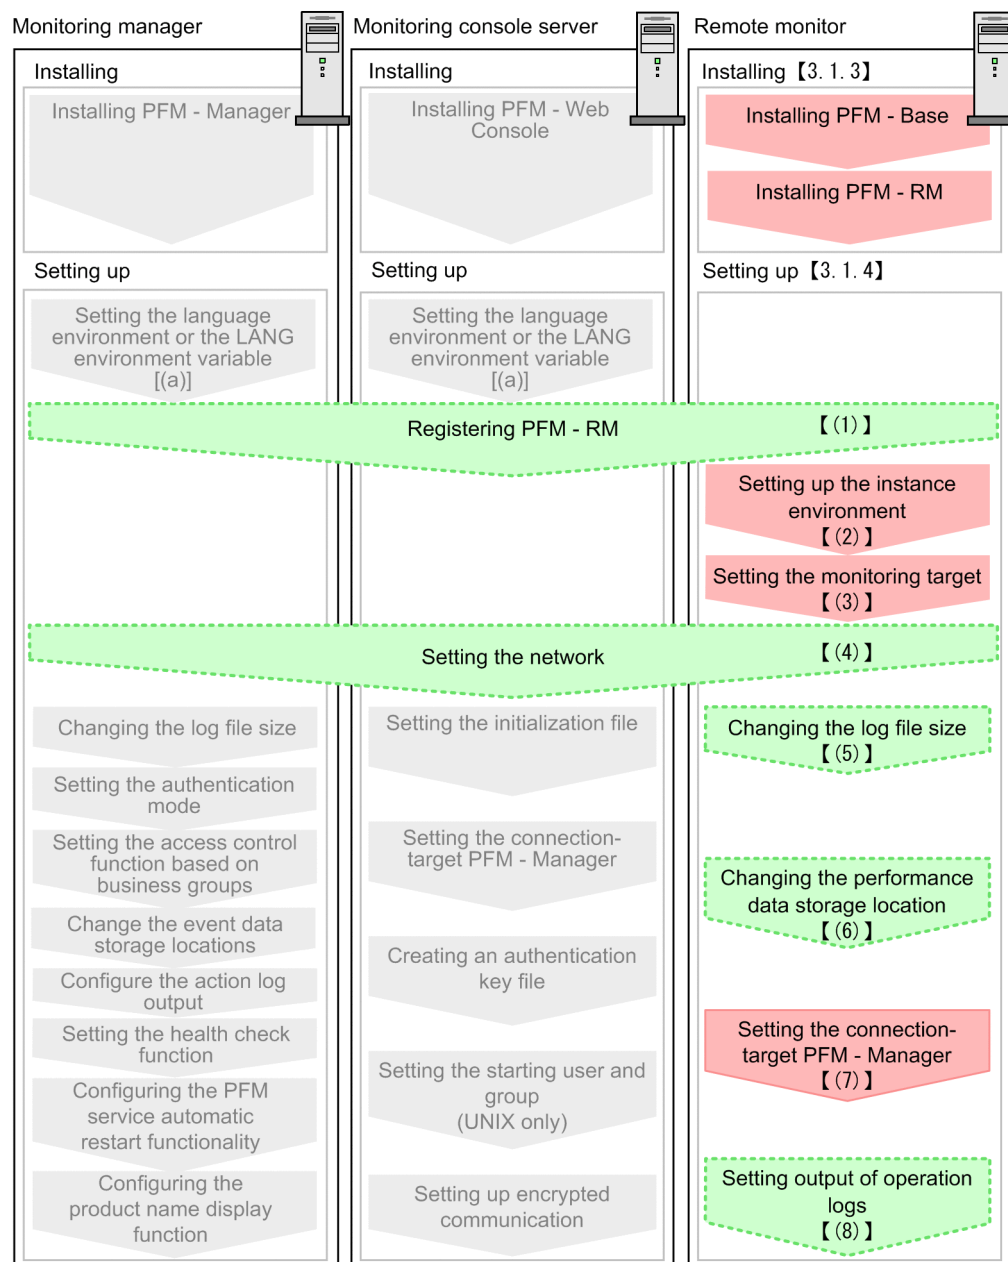

3.1.2 Flow of installation and setup for the Windows edition

This subsection describes the procedures for installing and setting up PFM - RM for Platform.

For details about how to install and set up PFM - Manager and PFM - Web Console, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

The following figure shows the procedures for installing and setting up PFM - RM for Platform.

Figure 3–3: Installation and setup procedures (for Windows)

Note:

These procedures are applicable when PFM - RM for Platform is installed on a host other than the PFM - Manager host.

For setup commands that require a user input, you can choose whether to execute the commands in the interactive or non-interactive mode.

When a command is executed in the interactive mode, the user must enter a value by following the instruction from the command.

When a command is executed in the non-interactive mode, no user input is required because an option specification or a definition file replaces the input step required during command execution. Furthermore, batch processing or remote execution can automate the setup procedure, thereby reducing the workload on the administrator and the cost of operations.

For details about commands, see the manual *JP1/Performance Management Reference*.

3.1.3 Installation procedure for the Windows edition

This subsection describes how to install PFM - RM for Platform in a Windows environment.

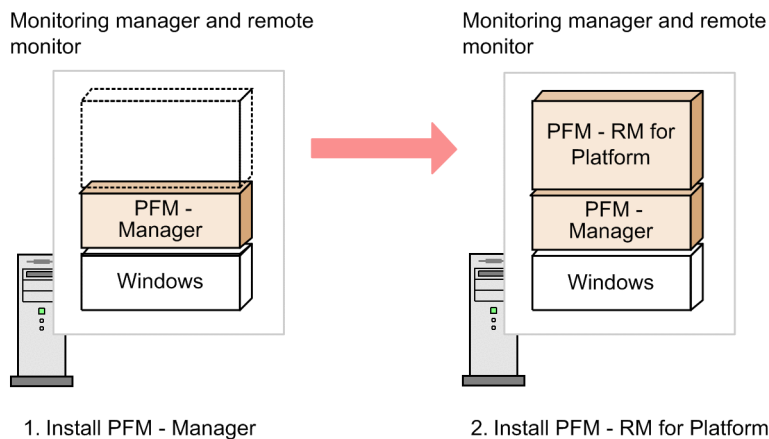

(1) Program installation sequence

This subsection describes the order in which PFM - RM for Platform and its prerequisite programs are to be installed.

When installing PFM - RM for Platform on the PFM - Manager host

Install PFM - Manager first, and then install PFM - RM for Platform.

Figure 3–4: Program installation sequence (when PFM - RM for Platform and PFM - Manager are on the same host (for Windows))

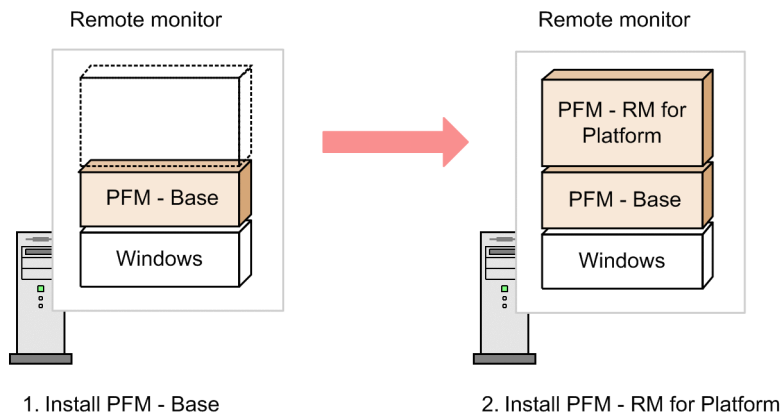

Legend:

-  : Program provided by Performance Management
-  : Required program

When installing PFM - RM for Platform on a host other than the PFM - Manager host

Install PFM - Base first, and then install PFM - RM for Platform.

Figure 3–5: Program installation sequence (when PFM - RM for Platform and PFM - Base are on the same host (for Windows))

Legend:

 : Program provided by Performance Management

 : Required program

If you install multiple PFM - RMs on the same host, you can install the individual PFM - RMs in any order.

(2) Installation procedure

This subsection describes how to install PFM - RM for Platform.

There are two ways to install PFM - RM for Platform in a Windows environment: by using the distribution media or by using JP1/Software Distribution for remote installation. For details about the method that uses JP1/Software Distribution, see the *JP1/Software Distribution Administrator's Guide Volume 1*, for Windows systems.

! Important

If user account control functionality (UAC) is enabled on the operating system, the User Account Control dialog box might be displayed during installation. If this dialog box is displayed, click the **Continue** button to continue installation, or click the **Cancel** button to cancel installation.

To install from the distribution media:

1. At the host where PFM - RM for Platform is to be installed, log on as a user with Administrator permissions.
2. Stop any Performance Management services running on the local host.
You must stop all Performance Management services running on physical and logical hosts. For details about how to stop services, see the chapter that describes starting and stopping Performance Management in the *JP1/Performance Management User's Guide*.
3. Insert the distribution media into the appropriate drive, and execute the installer.
Proceed with the installation in accordance with the instructions given by the installer that has been started.
You can view the following items that were specified when PFM - Manager or PFM - Base was installed:
 - User information
 - Installation folder

- Program folder

4. Click the **Install** button to start the installation.

3.1.4 Setup procedure for the Windows edition

This subsection describes how to set up PFM - RM for Platform.

 indicates the following setup items:

- Setup item required depending on the environment in use
- Setup item for changing a default setting

(1) Registering PFM - RM for Platform

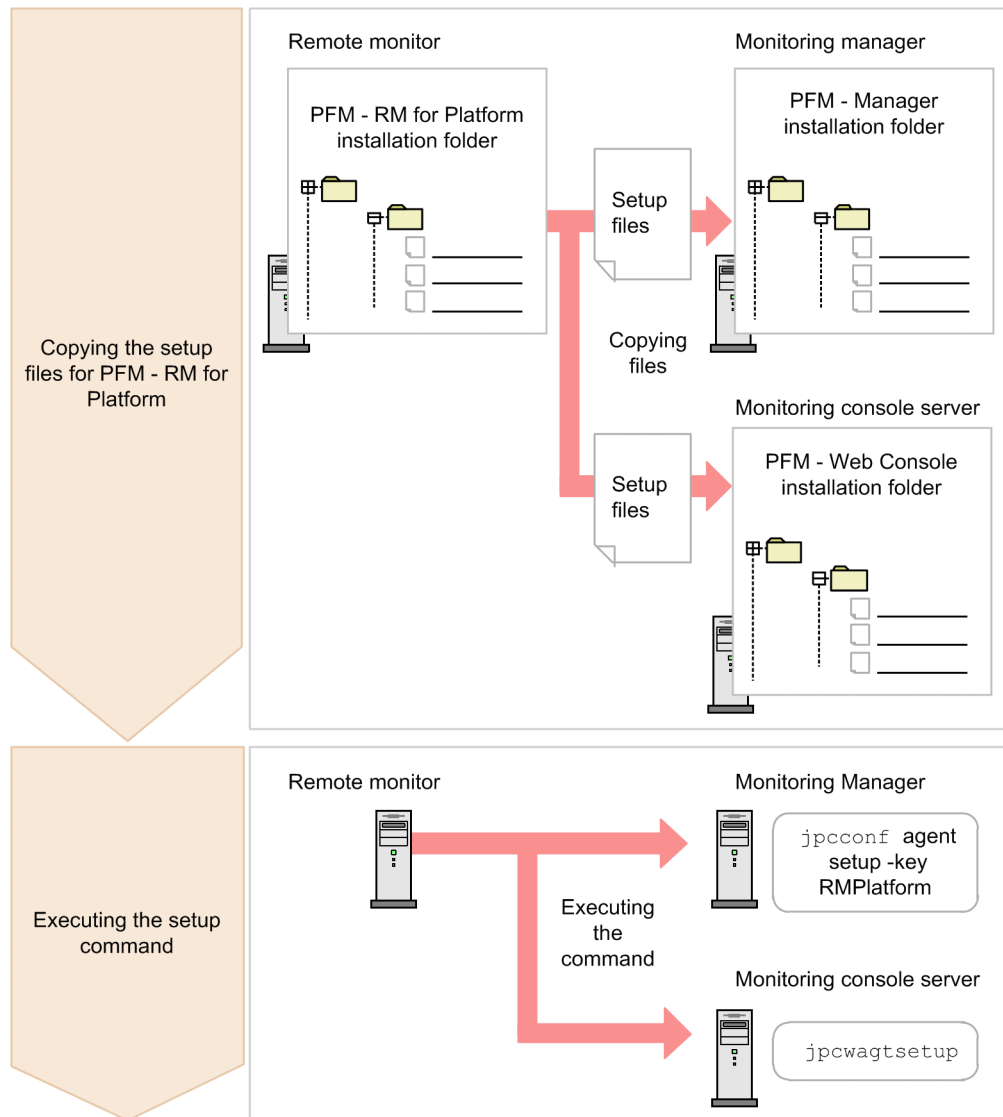

To achieve central management of PFM - RM for Platform in the Performance Management system, you must register PFM - RM for Platform into PFM - Manager and PFM - Web Console.

You must register PFM - RM for Platform at the following times:

- Whenever you add a new PFM - RM for Platform to the Performance Management system.
Note: If a PFM - RM for Platform has already been registered and you are adding a new PFM - RM for Platform of the same version, there is no need to register the new PFM - RM for Platform.
- When you update the Data model version for the registered PFM - RM for Platform.

The following figure shows the procedure for registering PFM - RM for Platform.

Figure 3–6: Procedure for registering PFM - RM for Platform (for Windows)

Notes about registering PFM - RM for Platform

- Register PFM - RM for Platform before you set up an instance environment.
- If you install different versions of PFM - RM for Platform on separate hosts, set up old versions before you set up new versions.
- If you install PFM - RM for Platform on the same host as where PFM - Manager is installed, the `jpcconf agent setup` command executes automatically.
- When PFM - RM for Platform is registered, folders named `RMPlatform` are created on the **Reports** and **Alarms** pages of PFM - Web Console. If you have already created a folder or file named `RMPlatform` on the **Reports** page, you must rename it before starting the registration procedure.

The following subsections describe how to register PFM - RM for Platform.

(a) Copying the setup files for PFM - RM for Platform

Copy the setup files from the PFM - RM host to the hosts where PFM - Manager and PFM - Web Console are installed.

To copy the setup files:

1. Stop PFM - Web Console.

If PFM - Web Console is running, stop it.

2. Copy the setup files in the binary mode.

Copy the files from the PFM - RM host to the PFM - Manager and PFM - Web Console hosts.

The following table lists the source file storage locations and the copy destination locations.

Table 3–7: Setup files to be copied (for Windows)

No.	Source (setup files for PFM - RM for Platform)	Target		
		Program name	OS	Target folder
1	<i>installation-folder\setup\jpcagt7w.EXE</i>	PFM - Manager	Windows	<i>PFM-Manager-installation-folder\setup</i>
2	<i>installation-folder\setup\jpcagt7u.Z</i>		UNIX	<i>/opt/jp1pc/setup/</i>
3	<i>installation-folder\setup\jpcagt7w.EXE</i>	PFM - Web Console	Windows	<i>PFM-Web-Console-installation-folder\setup</i>
4	<i>installation-folder\setup\jpcagt7u.Z</i>		UNIX	<i>/opt/jp1pcwebcon/setup/</i>

(b) Executing the setup command at the PFM - Manager host

At the PFM - Manager host, execute the setup command for PFM - RM for Platform.

Execute the following command:

```
jpcconf agent setup -key RMPlatform
```

This example shows execution in the interactive mode, but you can also execute the `jpcconf agent setup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

Notes about executing the command

Before you execute the command, stop all Performance Management programs and services. An error might occur if the `jpcconf agent setup` command is executed before all Performance Management programs and services have stopped completely. If an error has occurred, re-execute the `jpcconf agent setup` command.

After you have executed the setup command at the PFM - Manager host, you might delete the setup files for PFM - RM for Platform that were copied to the PFM - Manager.

(c) Executing the setup command at the PFM - Web Console host

At the PFM - Web Console host, execute the setup command for PFM - RM for Platform.

Execute the following command:

```
jpcwagtsetup
```

After you have executed the setup command at the PFM - Web Console host, you might delete the setup files for PFM - RM for Platform that were copied to the PFM - Web Console.

(2) Setting up an instance environment

Set up an instance environment for PFM - RM for Platform on the PFM - RM host. To set up multiple instance environments, repeat this procedure. With PFM - RM for Platform, you can define a maximum of 50 monitoring targets in a single instance environment.

Monitored hosts running Windows and those running UNIX can coexist within a single instance.

Using common account information in an instance environment

If you specify `Y` for the `UseCommonAccount` instance environment setting item, common account information (pfmhost) that was created beforehand for the instance environment is used.

The following table lists the correspondence between instance environment setting items and common account information setting items.

Table 3–8: Correspondence between instance environment setting items and common account information setting items

Instance environment setting item	Common account information (pfmhost) setting item	Description
RMHost_User	User	User name
RMHost_Password	Password	Password
RMHost_Domain	Domain	Domain name

Note 1:

Common account information must be created on the PFM - RM host beforehand. Use the `jpccconf acc setup` command to create common account information. For details about the `jpccconf acc setup` command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

Note 2:

The settings and precautions required for creating common account information (pfmhost) are the same as for the corresponding instance environment setting items. See the corresponding instance environment setting items in [Table 3-10](#).

Notes about setting up instance environments

- Before you set up an instance environment, make sure that the applicable procedure described in one of the following sections has been completed and the correct environment has been set up:
 - [3.1.1\(5\) Environment settings required for collecting performance data \(when both the PFM - RM host and the monitored hosts are running Windows\)](#)
 - [3.1.1\(6\) Environment settings required for collecting performance data \(when the PFM - RM host is running Windows and the monitored hosts are running UNIX\)](#)
- Even if an invalid value is specified in the instance environment settings, the command for generating an instance environment terminates normally. However, if you begin collecting records with invalid settings, performance data is not collected. For details about troubleshooting when performance data is not collected, see [9.2.3 PFM - RM for Platform was started, but no performance data is being collected](#).

(a) Instance environment setting items that must be specified depending on what is monitored in the instance

The instance environment setting items that must be specified differ depending on what is monitored in the instance. The following table lists and describes the instance environment setting items that must be specified for each monitoring target in the instance.

Table 3–9: Instance environment setting items that must be specified for each monitoring target in the instance

Item name	What is monitored in the instance		
	Windows environment	UNIX environment	Health check monitoring
UseCommonAccount	D	D	D
Interval	D	D	T
Std_Category	D	D	T
Disk_Category	D	D	T
Network_Category	D	D	T
Ps_Category	D	D	T
RMHost_User	Y	Y	Y
RMHost_Password	Y	Y	Y
RMHost_Domain	D	D	D
SSH_Client	N	Y	N
Perl_Module	N	Y	N
Log_Size	D	D	D

Legend:

Y: Specification is required.

D: Specification is required if the default value is to be changed.

T: There is no need to change the default value.

N: Specification is not required.

(b) Instance environment setting items and values

The table below lists and describes the instance environment setting items and values. Check this information before you start operations.

Use the `jpcconf inst setup` command to set up an instance environment.

For details about how to execute the `jpcconf inst setup` command, see [\(d\) Execution in the interactive mode](#) and [\(e\) Execution in the non-interactive mode](#).

For details about the `jpcconf inst setup` command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

Table 3–10: Instance environment setting items and values for PFM - RM for Platform (for Windows)

No.	Item name ^{#1}	Description	Setting	Default
1	UseCommonAccount	Specifies whether to use common account information.	Specify one of the following values: • Y: Use • N: Do not use	N
2	Interval	Specifies a collection interval for the collection process.	Specify a value in the range from 60 to 3,600 (seconds).	300

No.	Item name ^{#1}	Description	Setting	Default
3	Std_Category ^{#2}	Specifies whether the collection process is to collect basic information (PI and PI_CPU records).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	Y
4	Disk_Category ^{#2}	Specifies whether the collection process is to collect disk information (PI_PDSK and PI_LDSK records).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	Y
5	Network_Category ^{#2}	Specifies whether the collection process is to collect network information (PI_NET record).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	Y
6	Ps_Category ^{#2}	Specifies whether the collection process is to collect process information (PD_APS, PD_ASVC, PD_APP2, PD_APPC, and PD_APPD records).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	Y
7	RMHost_User ^{#3}	Specifies the user account ^{#4} used on the PFM - RM host.	From 1 to 256 bytes of characters can be specified. The tab character cannot be used.	--
8	RMHost_Password	Specifies the password for the account used on the PFM - RM host. The characters entered in this item are not displayed on the screen. If you specify this password, you are prompted to confirm the password by entering it again.	From 1 to 256 bytes of characters can be specified. The tab character cannot be used.	--
9	RMHost_Domain ^{#5}	Specifies the domain name to which the account used on the PFM - RM host belongs. There is no need to specify this item if the account belongs to a workgroup.	From 0 to 256 bytes of characters can be specified. The tab character cannot be used.	No domain name is specified.
10	SSH_Client ^{#5}	Specifies an absolute path for the execution module (plink.exe) of the SSH client (PuTTY). Even if the file path contains a space, there is no need to enclose the file path in double quotation marks ("). There is no need to specify this item if all of the monitored hosts in the instance are only running Windows.	From 0 to 256 bytes of characters can be specified. The tab character cannot be used.	No SSH client execution module is specified.
11	Perl_Module ^{#5}	Specifies an absolute path for the execution module (perl.exe) of Perl (ActivePerl). Even if the file path contains a space, there is no need to enclose the file path in double quotation marks ("). There is no need to specify this item if all of the monitored hosts in the instance are only running Windows.	From 0 to 256 bytes of characters can be specified. The tab character cannot be used.	No Perl execution module is specified.
12	Log_Size	Specifies the maximum size of one agent log file. ^{#7}	Specify a value in the range from 1 to 32 (megabytes).	3

Legend:

--: No default is set.

#1

When the `jpcconf inst setup` command is executed in the non-interactive mode, this item name is used as a product-specific label in the definition file. For details about commands in the non-interactive mode, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

#2

The settings for `Std_Category`, `Disk_Category`, `Network_Category`, and `Ps_Category` are given higher priority than the collection settings for the individual records.

For example, if you set `Std_Category` to `N` (do not collect), a PI record is handled as follows:

- The PI record information is not recorded in the Store database.
- If an attempt is made to display a real-time report based on PI records from the PFM - Web Console, the KAVJS5001-I error message is displayed.
- If an alarm is bound to a PI record, that alarm does not function.

#3

PFM - RM for Platform starts the collection process by using the user account specified in `RMHost_User`. When adding or modifying an instance environment, you need to create a new user account and specify it for `RMHost_User`. However, if a profile for the newly created user account already exists, collection of performance data might fail. In such a case, log on to Windows again by using the newly created user account.

If the system is being run with enhanced file permissions, the user specified for `RMHost_User` must belong to the PFM operation group. For details about operations with enhanced file permissions, see the chapter that describes file permission enhancement in the *JP1/Performance Management Planning and Configuration Guide*.

To specify the local host as a monitored host when the user account control functionality (UAC) is enabled on the PFM - RM host, specify the local account's Built-in Administrator for `RMHost_User` in the instance settings.

Note that the following check boxes in the **General** tab of the **Administrator Properties** window must not be selected:

- **User must change password at next logon**
- **Account is disabled**

These notes also apply when `User` in common account information (`pfmhost`) is used. In this case, read these notes with `User` replacing `RMHost_User` in common account information (`pfmhost`).

#4

If you run PFM - RM for Platform in a cluster system, specify an account that can log on to both the active node and the standby node by using the same user name and password.

This also applies when `User` is used in the common account information (`pfmhost`).

#5

If both of the following conditions are met when the local host is monitored, specify the local host name for `RMHost_Domain`:

- The PFM - RM host is running Windows
- The PFM - RM host is a participant in a domain.

#6

You must specify this item if the instance includes a monitored host running UNIX. Additionally, when operating PFM - RM for Platform in a cluster system, specify a file path that can be accessed from both the active server and the standby server.

#7

Use the following formula for estimating the agent log size:

$$\text{agent-log-size (megabytes)} = ((a \times 24 \times 3,600) / b \times 4) / (4 \times 1,024)$$

Legend:

a: Number of days to retain the agent log

b: Instance interval value

In the agent log, a maximum of $(16 + \text{number-of-monitoring-targets} \times 4)$ files are collected per instance.

If the hard disk does not have sufficient free space, the agent log generates an output error. For details about the agent log, see [9.3 Log information to be collected for troubleshooting](#).

(c) Instance environment setting items that are not displayed

Instance environment setting items are usually displayed by executing a command, but some might not be displayed depending on the contents of other setting items or for some other reason. The table below lists and describes conditions that prevent instance environment setting items from being displayed. It also shows the input values that are used in such cases.

Table 3–11: Conditions that prevent instance environment setting items from being displayed, and input values that are used

Item name	Conditions that prevent instance environment setting items from being displayed, and input values that are used
RMHost_User	These items are not displayed when Y is specified for UseCommonAccount. Input value: The value in the corresponding common account information is used as the input value. For details about the corresponding common account information, see Table 3-8 .
RMHost_Password	
RMHost_Domain	

(d) Execution in the interactive mode

1. Execute the `jpccconf inst setup` command.

The following example sets up an instance environment using `inst1` as the instance name:

```
jpccconf inst setup -key RMPlatform -inst inst1
```

2. Set up an instance environment for PFM - RM for Platform.

Enter each instance environment setting item for PFM - RM for Platform according to the instructions given by the command. For details about each instance environment setting item, see [Table 3-10](#). After you input each setting item, press the **Enter** key. To use a displayed default value, simply press the **Enter** key.

The following is a setting example in which the instance includes a monitored host running UNIX:

```
C:\Program Files\Hitachi\jplpc\tools>jpccconf inst setup -key RMPlatform -
inst inst1
UseCommonAccount      [N]                      :<Enter>
Interval               [300]                    :<Enter>
Std_Category           [Y]                      :<Enter>
Disk_Category          [Y]                      :<Enter>
Network_Category       [Y]                      :<Enter>
Ps_Category            [Y]                      :<Enter>
RMHost_User#1          :rmuser<Enter>
RMHost_Password#1      :rmpass#2<Enter>
Re-enter#1             :rmpass#2<Enter>
RMHost_Domain#1        []                       :<Enter>
SSH_Client              [] :C:\Program Files\PuTTY\plink.exe#3<Enter>
Perl_Module            [] :C:\Perl\bin\perl.exe#3<Enter>
Log_Size (MB)          [3]                      :<Enter>
KAVE05080-I The instance environment is now being created.
(servicekey#4=RMPlatform, inst=inst1)
KAVE05081-I The instance environment has been created.
(servicekey#4=RMPlatform, inst=inst1)
```

#1

This item is not displayed when Y is specified for UseCommonAccount.

#2

Re-entry of the password is prompted. The entered password is not displayed on the screen.

#3

Enter this line if the instance includes monitored hosts running UNIX. There is no need to enter this line if all monitored hosts in the instance are running Windows.

If the PFM - Manager's product name display function is disabled, agt7 is displayed for servicekey.

(e) Execution in the non-interactive mode

1. Execute the `jpccconf inst setup` command to create a definition file template.

Execute the command as follows:

```
jpccconf inst setup -key RMPlatform -noquery -template definition-file-name
```

Sections and labels that correspond to the instance environment setting items are output to a definition file. Note that the label of the Instance Definitions section is left blank.

2. Edit the definition file template created in step 1.

Edit the setting values as required for the instance environment.

For details about the product-specific labels to be specified in the definition file, see [Table 3-10](#).

Shown below is an example of a definition file for an instance environment in which the instance includes monitored hosts running UNIX. Specify values for the labels in the Instance Definitions section as required for the instance environment.

```
[Common Definitions]
Definition File Version=0001

[Product Information]
Product ID=7

[Instance Definitions]
UseCommonAccount=
Interval=
Std_Category=
Disk_Category=
Network_Category=
Ps_Category=
RMHost_User#1=rmuser
RMHost_Password#1=rmpass
RMHost_Domain#1=
SSH_Client= C:\Program Files\PuTTY\plink.exe#2
Perl_Module= C:\Perl\bin\perl.exe#2
Log_Size=
```

#1

There is no need to specify values for these items if Y is specified for UseCommonAccount.

#2

Enter this line if the instance includes monitored hosts running UNIX. There is no need to enter this line if all monitored hosts in the instance are running Windows.

3. Execute the `jpccconf inst setup` command to set up an instance environment for PFM - RM for Platform.

The following example sets up an instance environment using `inst1` as the instance name. For the `-input` option, specify the definition file edited in step 2.

```
jpccconf inst setup -key RMPlatform -inst inst1 -noquery -input definition-file-name
```

Note:

If the definition file contains confidential information such as passwords, save the definition file in a secure location, and delete it after you have used it. If you want to transfer the definition file between hosts, we recommend that you use a secure file transfer protocol, such as Secure File Transfer Protocol (SFTP), which is FTP over an SSH tunnel.

When all of the settings have been completed, an instance environment can be built. The following table shows the folder structure of an instance environment.

Table 3–12: Folder structure of an instance environment (for Windows)

No.	Storage folder	File name	Description
1	<i>installation-folder</i> ^{#1} \agt7\agent\ <i>instance-name</i>	jpcagt.ini	Service startup initialization file of Remote Monitor Collector
2		jpcagt.ini.lock	Lock file for the service startup initialization file of Remote Monitor Collector (for each instance)
3		jpcagt.ini.model ^{#2}	Sample of a service startup initialization file of Remote Monitor Collector
4		status.dat	Intermediate file for internal processing
5		tstatuses.dat	Virtual Agent status information ^{#3}
6		targetlist.ini	List of monitoring targets
7		grouplist.ini	List of groups
8		GARULES.DAT	Grouping rule description file
9		targets	Storage folder for remote agent
10		groups	Storage folder for group agent
11		log	Storage folder for log files
12	<i>installation-folder</i> ^{#1} \agt7\store\ <i>instance-name</i>	*.DB	Performance data file
13		*.IDX	Index files for performance data files
14		*.LCK	Lock files for performance data files
15		jpcsto.ini	Service startup initialization file of Remote Monitor Store
16		jpcsto.ini.model ^{#2}	Model file for the service startup initialization file of Remote Monitor Store
17		status.dat	Intermediate file for internal processing
18		*.DAT	Definition file for a data model
19		dump	Export folder
20		backup	Backup folder
21		partial	Partial backup folder
22		import	Import folder
23		log	Storage folder for log files

^{#1}

If you run a logical host, replace *installation-folder* with *environment-folder*\jp1pc. An environment folder is a folder on the shared disk that is specified when the logical host is created.

#2

Use these sample files when you want to restore the settings to their initial values from when the instance environment was configured.

#3

Created when the health check function is enabled.

To change an instance environment, re-execute the `jpccconf inst setup` command, and then update each instance environment setting. For details about updating the instance environment settings, see [3.6.2 Updating an instance environment](#).

You can change some settings by using PFM - Web Console to edit properties. For details about the information that can be changed by editing properties, see [E.1 List of properties of the Remote Monitor Store service](#).

In an instance environment, the service IDs and Windows service names are as follows:

Service IDs in an instance environment

- For the Remote Monitor Collector service
`7Ainstance-number instance-name [host-name]`
- For the Remote Monitor Store service
`7Sinstance-number instance-name [host-name]`
- For the Group Agent service
`7Ainstance-number instance-name [All@host-name]`

In PFM - RM for Platform, the instance name specified in the `jpccconf inst setup` command is displayed.

If the host name of the PFM - RM host is `host1`, and `inst1` is specified as the instance name, the service IDs will be as follows:

- For the Remote Monitor Collector service
`7A1inst1[host1]`
- For the Remote Monitor Store service
`7S1inst1[host1]`
- For the Group Agent service
`7A1inst1[All@host1]`

For details about the service IDs, see the naming rules provided in the appendix in the *JPI/Performance Management Planning and Configuration Guide*.

Windows service names in an instance environment

- For the Remote Monitor Collector service
PFM - RM for Platform *instance-name*
- For the Remote Monitor Store service
PFM - RM Store for Platform *instance-name*

If `inst1` is specified as the instance name, the service names will be as follows:

- For the Remote Monitor Collector service
PFM - RM for Platform `inst1`
- For the Remote Monitor Store service
PFM - RM Store for Platform `inst1`

For details about the Windows service names, see the naming rules provided in the appendix in the *JPI/Performance Management Planning and Configuration Guide*. For details about the Windows service names when a logical host

is used for operation, see the chapter that describes cluster system configuration and operation in the *JP1/Performance Management User's Guide*.

You cannot set up an instance environment by using PFM - Web Console's facility to distributing agent-specific properties.

(3) Setting the monitored host

Set information about the monitored host for the instance specified in (2) *Setting up an instance environment*. You can set a maximum of 50 monitored hosts for a single instance. To set multiple monitored hosts, repeat this procedure. However, if the number of monitored hosts is large, the desired performance might not be achieved depending on the machine's performance and environment. In such a case, reduce the number of monitored hosts. Carefully validate performance before starting operations.

For PFM - RM 11-00 or later, you can specify logical hosts as monitored hosts. Note, however, that you can specify logical hosts only when monitoring whether processes or services are running. For other monitoring, we recommend that you specify physical hosts.

Important

If you specify a logical host as a monitored host for any purpose other than monitoring whether processes or services are running, correct values will not be stored for the first performance data when the machine is switched.

Using common account information for monitored hosts

If Y is set for `UseCommonAccount` in the setting items for the monitored host, common account information[#] (wmi or ssh) that is created beforehand for the monitored host is used.

#

In health check monitoring, the common account information cannot be used.

The type of the common account information to be used differs depending on whether the OS of the monitored host is Windows or UNIX. The following table lists the correspondence between the OS of the monitored host and the type of common account information.

Table 3–13: Correspondence between the OS of the monitored host and the type of common account information

OS of the monitored host	Type of common account information
Windows	wmi
UNIX	ssh

The following tables list the correspondence between the setting items for the monitored host and those for common account information.

Table 3–14: Correspondence between the setting items for the monitored host and those for common account information (when the OS of the monitored host is Windows)

Setting items for the monitored host	Setting items for common account information (wmi)	Description
User	User	User name
Password	Password	Password
Domain	Domain	Domain name

Table 3–15: Correspondence between the setting items for the monitored host and those for common account information (when the OS of the monitored host is UNIX)

Setting items for the monitored host	Setting items for common account information (ssh)	Description
User	User	User name
Private_Key_File	Private_Key_File	Private key file name

Note 1:

Common account information must be created on the PFM - RM host beforehand. Use the `jpccconf acc setup` command to create common account information. For details about the `jpccconf acc setup` command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

Note 2:

The settings and precautions required for creating common account information (wmi or ssh) are the same as for the corresponding monitoring target setting items. See the corresponding monitoring target setting items in [Table 3-17](#).

Important

To use common account information, you need to unify the account information settings so that you can connect to multiple monitoring targets by using a single set of account information. For this reason, there is a risk of greater negative impact if common account information is leaked. To avoid such a risk, determine whether to use common account information after considering security measures and information management.

Notes about setting a monitored host

- Before you set up a monitored host, make sure that the applicable procedure in one of the following sections has been completed and the correct environment has been set up:
 - [3.1.1\(5\) Environment settings required for collecting performance data \(when both the PFM - RM host and the monitored hosts are running Windows\)](#)
 - [3.1.1\(6\) Environment settings required for collecting performance data \(when the PFM - RM host is running Windows and the monitored hosts are running UNIX\)](#)
- Even if an invalid value is specified in the monitored host settings, the command for generating a monitoring target terminates normally. However, if you begin collecting records with invalid settings, performance data will not be collected. For details about troubleshooting when performance data is not collected, see [9.2.3 PFM - RM for Platform was started, but no performance data is being collected](#).

(a) Monitoring target setting items that must be specified depending on what is monitored

The monitoring target setting items that must be specified differ depending on what is monitored. The following table lists and describes these monitoring target setting items that must be specified for each monitoring target.

Table 3–16: Monitoring target setting items that must be specified for each monitoring target

Item name	What is monitored		
	Windows environment	UNIX environment	Health check monitoring
Target Host	Y	Y	Y
UseCommonAccount	D	D	T
TargetType	T	Y	Y
User	Y	Y	N

Item name	What is monitored		
	Windows environment	UNIX environment	Health check monitoring
Password	Y	N	N
Domain	D	N	N
Private_Key_File	N	Y	N
Port	N	D	N

Legend:

Y: Specification is required.

D: Specification is required if the default value is being changed.

T: There is no need to change the default value.

N: Specification is not required.

(b) Monitoring target setting items and values

The table below lists and describes the setting items and values for a monitored host. Check this information before you start operations.

Use the `jpccconf target setup` command to set up a monitored host.

For details about how to execute the `jpccconf target setup` command, see [\(d\) Execution in the interactive mode](#) and [\(e\) Execution in the non-interactive mode](#).

For details about the `jpccconf target setup` command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

Table 3–17: Setting items and values for a monitored host in PFM - RM for Platform

No.	Item name ^{#1}	Description	Setting	Default
1	Target Host	Specifies the name of the monitored host ^{#2} . Specify a host name that can be resolved. ^{#3} The specified monitored host name is used during performance data collection ^{#4} and health checking. If JP1/IM is linked, this name is also used as the event host name.	From 1 to 32 bytes of alphanumeric characters and the hyphen (-) are permitted. The name cannot begin with a hyphen (-). The specified value must be unique within the instance. ^{#5}	No monitored host name is specified. ^{#6}
2	UseCommonAccount	Specifies whether to use common account information.	Specify one of the following values: <ul style="list-style-type: none"> Y: Use N: Do not use 	N
3	TargetType	Specifies the method for connecting to the monitored host. The value to be specified differs depending on whether the monitored host is running Windows or UNIX. For health check monitoring, the value should be <code>icmp</code> .	<ul style="list-style-type: none"> Specify <code>wmi</code> if the monitored host is running Windows. Specify <code>ssh</code> if the monitored host is running UNIX. Specify <code>icmp</code> for health check monitoring. 	<code>wmi</code>
4	User	Specifies the user ^{#7} , ^{#8} used to connect to the monitored host.	From 1 to 256 bytes of characters are permitted.	--

No.	Item name ^{#1}	Description	Setting	Default
4	User	Specifies the user ^{#7} , ^{#8} used to connect to the monitored host.	The tab character is not permitted.	--
5	Password ^{#9}	Specifies the password used to connect to the monitored host. The characters entered in this item are not displayed on the screen. When the password is specified, re-entry of the password is requested. There is no need to specify this item if the monitored host is running UNIX.	From 0 to 256 bytes of characters are permitted. The tab character is not permitted.	No password is specified.
6	Domain	Specifies the name of the domain ^{#10} to which the monitored host belongs. There is no need to specify this item if the monitored host belongs to a work group. There is no need to specify this item if the monitored host is running UNIX.	From 0 to 256 bytes of characters are permitted. The tab character is not permitted.	No domain name is specified.
7	Private_Key_File ^{#11}	Specifies an absolute path for the name of the private key file used in the SSH public key method. Even if the file path contains a space, there is no need to enclose the file path in double quotation marks (""). There is no need to specify this item if the monitored host is running Windows.	From 0 to 256 bytes of characters are permitted. The tab character is not permitted.	A private key file name is not specified.
8	Port	Specifies the port number of the SSH server on the monitored host. This item is not used if the monitored host is running Windows. In this case, leave the default value.	1 to 65,535	22

Legend:

--: No default is set.

#1

When the `jpccconf target setup` command is executed in the non-interactive mode, this item name is used as a product-specific label in the definition file. For details about commands in the non-interactive mode, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

#2

For health check monitoring, you can also specify hosts and hardware equipment that support the ICMP protocol (can communicate through `ping` command).

#3

To collect performance data and perform health checking, the name must be resolvable at least by the PFM - RM host.

If the JP1/IM linkage facility is used, the name must be resolvable by the JP1/IM host.

#4

Health check monitoring does not collect performance data.

#5

All cannot be used because it is a reserved word for group agents.

#6

If the specification is omitted, the host name of the PFM - RM host is assumed.

#7

If the monitored host is running Windows, the specified user must be a member of the monitored host's Administrators group, Performance Log Users group, or Performance Monitor Users group.

To perform operations such as Windows security audit, you also need permissions to execute such operations.

The type of records that can be collected differs according to the account type. For details about various account types and whether records can be collected, see [3.1.1\(5\)\(a\) Setting the user accounts](#).

If the monitored host is running Windows, note that the following check boxes in the **General** tab of the **Administrator Properties** window must not be selected:

- **User must change password at next logon**
- **Account is disabled**

In addition, if the monitored host specifies a domain user in an Active Directory environment, click the **Account** tab for that user, and then click the **Log On To** button to display the **Logon Workstations** window. In the **Logon Workstations** window, make sure that one of either of the conditions listed below exists there:

- The **All computers** option is selected.
- The **following computers** option is selected, and the host name of the monitored host is already registered.

If the monitored host resides in a work group environment, execute the `gpedit.msc` command to display the **Local Computer Policy** window, and select **Computer Configuration, Windows Settings, Security Settings, Local Policies**, and then **Security Options**. Then, make sure that the **Network access: Sharing and security model for local accounts** option is set to **Classic - local users authenticate as themselves**.

These notes also apply when `User` in common account information (wmi) is used.

#8

When the monitored host is running UNIX, use `bash`, `bsh`, or `ksh` for the login shell of the user to be specified.

This also applies when `User` in common account information (ssh) is used.

#9

This item is required if the monitored host is running Windows.

This also applies when `Password` in common account information (wmi) is used.

#10

When monitoring the local host, specify a local host name if all of the following conditions are satisfied:

- The PFM - RM host is a participant in a domain.
- The user of the PFM - RM host is used for connecting to the monitored host.

This also applies when `Domain` in common account information (wmi) is used. When using common account information, specify the local host name for `Domain` in common account information (wmi).

#11

This item is required if the monitored host is running UNIX.

Also, when operating PFM - RM for Platform in a cluster system, specify a file path that can be accessed from both the active server and the standby server.

This also applies when `Private_Key_File` in common account information (ssh) is used.

(c) Monitored host setting items that are not displayed

Monitored host setting items are usually displayed by executing a command, but some are not displayed depending on the contents of other setting items or for some other reason. The table below describes conditions that prevent monitored host setting items from being displayed. It also shows the input values that are used in such cases.

Table 3–18: Conditions that prevent monitored host setting items from being displayed, and input values that are used

Item name	Conditions that prevent monitored host setting items from being displayed, and input values that are used
User	<ul style="list-style-type: none"> This item is not displayed when Y is specified for UseCommonAccount. <p>Input value: The value in the corresponding common account information is used as the input value. For details about the corresponding common account information, see Table 3-14 or Table 3-15.</p> <ul style="list-style-type: none"> This item is not displayed when icmp is specified for TargetType.
Password	<ul style="list-style-type: none"> These items are not displayed when ssh or icmp is specified for TargetType. These items are not displayed when Y is specified for UseCommonAccount and wmi is specified for TargetType. <p>Input value: The value in the corresponding common account information is used as the input value. For details about the corresponding common account information, see Table 3-14.</p>
Domain	
Private_Key_File	<ul style="list-style-type: none"> This item is not displayed when wmi or icmp is specified for TargetType. This item is not displayed when Y is specified for UseCommonAccount and ssh is specified for TargetType. <p>Input value: The value in the corresponding common account information is used as the input value. For details about the corresponding common account information, see Table 3-15.</p>
Port	This item is not displayed when wmi or icmp is specified for TargetType.

(d) Execution in the interactive mode

1. Execute the `jpccconf target setup` command.

In PFM - RM for Platform, we recommend that you specify the host name of the monitored host as the name of the monitoring target.

The following example sets the monitored host `targethost1` with instance name `inst1` as the monitoring target:

```
jpccconf target setup -key RMPlatform -inst inst1 -target targethost1
```

2. Set up the monitoring target for PFM - RM for Platform.

Enter setting items for the monitored host according to the instructions given by the command. For details about the setting items for the monitored host, see [Table 3-17](#). After you input each setting item, press the **Enter** key to set it. To use a displayed default value, simply press the **Enter** key.

The following is an example of the settings when the monitored host is running Windows:

Conditions for the monitored host to be set up

- Host name: `targethost1`
- User: `user1`
- Password: `pass1`
- Domain: `domain1`

```
C:\Program Files\Hitachi\jplpc\tools>jpccconf target setup -key RMPlatform
-inst inst1 -target targethost1
Target Host          []                :targethost1<Enter>
UseCommonAccount     [N]              :<Enter>
TargetType           [wmi]             :<Enter>
User#1               :user1<Enter>
```

```

Password#1                :pass1#2<Enter>
Re-enter#1                 :pass1#2<Enter>
Domain#1                   []          :domain1<Enter>
KAVE05361-I The monitoring target is now being added.
(servicekey#3=RMPlatform, inst=inst1, target=targethost1)
KAVE05362-I The monitoring target has been added.
(servicekey#3=RMPlatform, inst=inst1, target=targethost1)

```

#1

This item is not displayed when Y is specified for UseCommonAccount.

#2

Re-entry of the password is prompted. The entered password is not displayed on the screen.

#3

If PFM - Manager's product name display function is disabled, agt7 is displayed for servicekey.

The following is an example of the settings when the monitored host is running UNIX:

Conditions for the monitored host to be set up

- Host name: targethost2
- User: ssh-user

```

C:\Program Files\Hitachi\jplpc\tools>jpcconf target setup -key RMPlatform
-inst inst1 -target targethost2
Target Host          []          :targethost2<Enter>
UseCommonAccount     [N]        :<Enter>
TargetType           [wmi]      :ssh<Enter>
User#1               :ssh-user<Enter>
Private_Key_File     [] :C:\Program Files\PuTTY\agt7.ppk<Enter>
Port                 [22]       :<Enter>
KAVE05361-I The monitoring target is now being added.
(servicekey#2=RMPlatform, inst=inst1, target=targethost2)
KAVE05362-I The monitoring target has been added.
(servicekey#2=RMPlatform, inst=inst1, target=targethost2)

```

#1

This item is not displayed when Y is specified for UseCommonAccount.

#2

If PFM - Manager's product name display function is disabled, agt7 is displayed for servicekey.

The following is an example of the settings for health check monitoring:

Conditions for the monitored host to be set up

- Host name: targethost3

```

C:\Program Files\Hitachi\jplpc\tools>jpcconf target setup -key RMPlatform
-inst inst1 -target targethost3
Target Host          []          :targethost3<Enter>
UseCommonAccount     [N]        :<Enter>
TargetType           [wmi]      :icmp<Enter>
KAVE05361-I The monitoring target is now being added.
(servicekey#=RMPlatform, inst=inst1, target=targethost3)
KAVE05362-I The monitoring target has been added.
(servicekey#=RMPlatform, inst=inst1, target=targethost3)

```

#

If PFM - Manager's product name display function is disabled, agt7 is displayed for servicekey.

(e) Execution in the non-interactive mode

1. Execute the `jpcconf target setup` command to create a definition file template.

Execute the command as follows:

```
jpcconf target setup -key RMPlatform -noquery -template definition-file-name
```

Sections and labels that correspond to the monitored host setting items are output to a definition file. Note that the value for the label of the Target Definitions section is left blank.

2. Edit the definition file template created in step 1.

Edit the template setting values as required for the monitored host.

For details about the product-specific labels to be specified in the definition file, see [Table 3-17](#).

Shown below is an example of the coding of a definition file when the monitored host is running Windows. Specify values for the labels in the Target Definitions section as required for the monitored host.

```
[Common Definitions]
Definition File Version=0001

[Product Information]
Product ID=7

[Target Definitions]
Target Host=targethost1
UseCommonAccount=
TargetType=
User#=user1
Password#=pass1
Domain#=domain1
Private_Key_File=
Port=
```

#

There is no need to specify a value for this item when Y is specified for UseCommonAccount.

Shown below is an example of the coding of a definition file when the monitored host is running UNIX. Specify values for the labels in the Target Definitions section as required for the monitored host.

```
[Common Definitions]
Definition File Version=0001

[Product Information]
Product ID=7

[Target Definitions]
Target Host=targethost2
UseCommonAccount=
TargetType=ssh
User#=ssh-user
Password=
Domain=
```

```
Private_Key_File#= C:\Program Files\PuTTY\agt7.ppk
Port=
```

#

There is no need to specify a value for this item when Y is specified for UseCommonAccount.

Shown below is an example of the coding of a definition file for health check monitoring. Specify values for the labels in the Target Definitions section as required for the monitored host.

```
[Common Definitions]
Definition File Version=0001

[Product Information]
Product ID=7

[Target Definitions]
Target Host=targethost3
UseCommonAccount=
TargetType=icmp
User=
Password=
Domain=
Private_Key_File=
Port=
```

3. Execute the `jpcconf target setup` command to set up the monitoring target for PFM - RM for Platform.

The following example sets up a monitoring target where `inst1` is the instance name and `targethost1` is the monitored host. For the `-input` option, specify the definition file edited in step 2.

```
jpcconf target setup -key RMPlatform -inst inst1 -target targethost1 -
input definition-file-name -noquery
```

Note:

If the definition file contains confidential information such as passwords, save the definition file in a secure location, and delete it after you have used it. If you want to transfer the definition file between hosts, we recommend that you use a secure file transfer protocol, such as Secure File Transfer Protocol (SFTP), which is FTP over an SSH tunnel.

When all of the settings have been completed, a monitoring target environment can be built. The following table shows the folder structure of the monitoring target environment.

Table 3–19: Folder structure of the monitoring target environment

No.	Storage folder	File name	Description
1	<i>installation-folder</i> #\agt7\agent\instance-name\targets	<i>monitoring-target-name.ini</i>	Monitoring target settings file
2		<i>monitoring-target-name.ini.model</i>	Sample of a monitoring target settings file
3	<i>installation-folder</i> #\agt7\agent\instance-name\targets\monitoring-target-name	--	Work folder for the monitoring target

Legend:

--: Not applicable

#

If you run a logical host, replace *installation-folder* with *environment-folder\jplpc*.

The following service IDs are added by the monitoring target settings:

Service IDs to be added

- Remote Agent service

`7Ainstance-number instance-name [monitoring-target-name@host-name]`

The instance name and monitoring target name will be the values specified in the `jpccnf target setup` command.

If you specify `host1` as the host name of the PFM - RM host, `inst1` as the instance name, and `targethost1` as the monitoring target name, the service ID will be as follows:

`7Ainst1[targethost1@host1]`

For details about the service IDs, see the naming rules provided in the appendix in the *JPI/Performance Management Planning and Configuration Guide*.

If you want to change information about the monitoring target, re-execute the `jpccnf target setup` command and update the information. For details about updating a monitoring target, see [3.6.3 Updating a monitoring target](#).

You can change some settings by using PFM - Web Console to edit properties. For details about the information that can be changed by editing properties, see [E.3 List of properties of remote agents and group agents](#).

(4) Network settings Optional

You must specify network settings only if you need to change the network environment settings for the network configuration where Performance Management is used.

There are two types of network environment settings, as described below. Change network settings as necessary.

- IP address setting

Set this information to use Performance Management in a network that is connected to multiple LANs. You set multiple IP addresses by defining the host names and IP addresses in the `jpchosts` file. Make sure that the specified `jpchosts` file is consistent throughout the entire Performance Management system.

For details about the IP address settings, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

- Port number setting

Set the port numbers used by Performance Management. To avoid confusion during operation, make sure that the specified port numbers and service names are consistent throughout the entire Performance Management system.

For details about the port number settings, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

(5) Changing the log file size Optional

The operation status of Performance Management is output to log files unique to Performance Management. This setting is required in order to change the size of these log files.

These unique log files are called the *common message log*.

For the common message log, two files with a size of 2,048 kilobytes each are used by default. For details about changing the common message log, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

(6) Changing performance data storage locations Optional

These settings are required in order to change the following settings for the performance data that is managed by PFM - RM for Platform:

- Database storage location
By default, *installation-folder\agt7\store\instance-name* is set.
- Backup location
By default, *installation-folder\agt7\store\instance-name\backup* is set.
- Partial backup location
By default, *installation-folder\agt7\store\instance-name\partial* is set.
- Export location
By default, *installation-folder\agt7\store\instance-name\dump* is set.
- Import location
By default, *installation-folder\agt7\store\instance-name\import* is set.

Note:

If you use a logical host for operation, replace *installation-folder* with *environment-folder\jplpc*.

For details about changing performance data storage locations, see [3.6.1 Changing performance data storage locations](#).

(7) Setting the connection-target PFM - Manager

You must specify on the PFM - RM host information about the PFM - Manager that manages PFM - RM for Platform. The `jpcconf mgrhost define` command is used to make this setting.

Notes about setting the connection-target PFM - Manager

- Only one PFM - Manager can be set as the connection destination even when multiple PFM - RMs are installed on the same host. A different PFM - Manager cannot be specified for each PFM - RM.
- If PFM - RM for Platform and PFM - Manager are installed on the same host, then the PFM - Manager on the local host is the connection-target PFM - Manager. In this case, you cannot change the connection-target PFM - Manager to any other PFM - Manager. To connect to PFM - Manager on a remote host, install PFM - RM for Platform on a different host than for PFM - Manager.

To set the connection-target PFM - Manager:

1. Stop the Performance Management programs and services.

If any Performance Management programs and services are running on the local host, stop all of them before starting the setup procedure. If Performance Management programs and services are running during execution of the `jpcconf mgrhost define` command, a message is displayed that asks you to terminate them.

For details about how to stop services, see the chapter that describes starting and stopping Performance Management in the *JP1/Performance Management User's Guide*.

2. Execute the `jpcconf mgrhost define` command with the host name of the connection-target PFM - Manager specified.

The following shows an example of command execution when the connection-target PFM - Manager is located on the `host01` host:

```
jpcconf mgrhost define -host host01
```

This example shows execution in the interactive mode, but you can also execute the `jpcconf mgrhost define` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

(8) Action log output settings Optional

These settings are required in order to output action logs at the following times:

- When a PFM service starts
- When a PFM service stops
- When the PFM - Manager connection status is changed

An action log contains log information about exceeded threshold values caused by factors such as system overloads; its output is linked with the alarm function. For details about the action log output settings, see [I. Outputting Action Log Data](#).

3.1.5 WMI connection setting method (when both the PFM - RM host and the monitored host are running Windows)

This subsection explains how to set up the WMI connection settings necessary for collecting performance data from a monitored host running Windows.

To connect WMI, settings for the following are required:

- DCOM
The DCOM setting must be made at both the PFM - RM host and the monitored hosts.
If you run the PFM - RM host in a cluster system, the DCOM setting must be made at both the executing node and the standby node.
- Firewall
Set the firewall on each monitored host, as necessary.
- WMI namespace
Set the WMI namespace on each monitored host, as necessary.

When you have finished making the settings, check that you can connect from the PFM - RM host to the monitored hosts.

Notes about WMI connection setting

- Data cannot be collected when **Disabled** is set as the startup type of the Windows Management Instrumentation service (service name: `WinMgmt`) that provides system administration information for the OS of a monitored host.
- The type of records that can be collected differs according to the account type. For details about various account types and whether records can be collected, see [3.1.1\(5\)\(a\) Setting the user accounts](#).

(1) DCOM setting

This subsection describes how to set DCOM at the PFM - RM host and the monitored hosts.

(a) Setting at the PFM - RM host

Set DCOM at the PFM - RM host.

To set DCOM:

1. From the Windows **Start** menu, choose **Run**.
2. Enter `dcomcnfg.exe`, and then click the **OK** button.
The Component Services window appears.
3. Click **Component Services** and **Computers** to expand the tree.
4. Choose **My Computer**, and then from the right-click menu, choose **Properties**.
The My Computer Properties dialog box appears.
5. Choose the **Default Properties** tab, and then select **Enable Distributed COM on this computer**.
6. Click the **OK** button.
The My Computer Properties dialog box closes.
7. Restart the machine.
This step is not needed if you have not changed the setting of **Enable Distributed COM on this computer**.

(b) Setting at a monitored host

Set DCOM at each monitored host.

Some parts of the procedure might differ depending on the OS environment of a specific monitored host, as described below:

- If the OS of the monitored host is Windows Server 2003 with no service pack applied, there is no **Edit Limits** button, which means that there is no need to perform steps 6 through 11.
- If the OS of the monitored host is Windows Server 2008 or later and the UAC security facility is enabled, set DCOM for the user itself or for a group to which the user belongs, except for the Users or Administrators group.

To set DCOM:

1. From the Windows **Start** menu, choose **Run**.
2. Enter `dcomcnfg.exe`, and then click the **OK** button.
The Component Services dialog box appears.
3. Click **Component Services** and **Computers** to expand the tree.
4. Choose **My Computer**, and then from the right-click menu, choose **Properties**.
The My Computer Properties dialog box appears.
5. Choose the **Default Properties** tab, and then select **Enable Distributed COM on this computer**.
6. Choose the **COM Security** tab, and then click the **Edit Limits** button for **Access Permissions**.
The Access Permission dialog box appears.
Check to see if the user who connects to the monitored host or the group to which the user belongs is displayed in **Group or user names**.

If it is not displayed, click the **Add** button, and then add the user or the group to which the user belongs.

7. In **Group or user names**, select the user who connects to the monitored host or the user's group.

Check to see if **Allow** is selected in **Remote Access**. If this option is not selected, select it.

8. Click the **OK** button.

The Access Permission dialog box closes.

9. Choose the **COM Security** tab, and then click the **Edit Limits** button for **Launch and Activation Permissions**.

The Launch Permission dialog box appears.

Check to see if the user who connects to the monitored host or the group to which the user belongs is displayed in **Group or user names**.

If it is not displayed, click the **Add** button, and then add the user or the group to which the user belongs.

10. In **Group or user names**, select the user who connects to the monitored host or the user's group.

Check to see if **Allow** is selected for both **Remote Launch** and **Remote Activation**. If it is not selected, select it.

11. Click the **OK** button.

The Launch Permission dialog box closes and the My Computer Properties dialog box is displayed again.

12. Click the **OK** button.

The My Computer Properties dialog box closes.

13. Restart the machine.

This step is not needed if you have not changed the setting of **Enable Distributed COM on this computer**.

(2) Firewall setting

This setting is required when a Windows firewall is enabled.

To determine if the firewall setting is enabled or disabled, from the Windows **Start** menu, choose **Control Panel**, and then **Windows Firewall**.

If the OS of the monitoring target is Windows Server 2003 with no service pack applied, then the Windows firewall function is not supported, and this setting is not needed.

To set the firewall:

1. From the Windows **Start** menu, choose **Run**.

2. Enter `gpedit.msc`, and then click the **OK** button.

The Group Policy dialog box appears.

3. Click **Computer Configuration**, **Administrator Templates**, **Network**, **Network Connections**, and **Windows Firewall** to expand the tree.

4. Click **Standard Profile**,^{#1} and then in the right-hand pane, from the right-click menu of **Windows Firewall: Allow remote administration exception**,^{#2} choose **Properties**.

The Windows Firewall: Allow remote administration exception Prop. dialog box appears.

#1

If the host machine is a domain environment, this will be **Domain Profile**.

#2

If the OS of the monitored host is Windows Server 2008 or later, this will be **Windows Firewall: Allow remote administration exception**.

5. Choose the **Setting** tab, and then select **Enabled**.

6. Click the **OK** button.

The Windows Firewall: Allow remote administration exception Prop. dialog box closes.

(3) WMI namespace setting

This subsection explains the procedure for setting the WMI namespace.

If the OS of the monitored host is Windows Server 2008 or later and the UAC security facility is enabled, set the WMI namespace security for the user itself or for a group to which the user belongs, except for the Users or Administrators group.

To set the WMI namespace security:

1. From the Windows **Start** menu, choose **Run**.

2. Enter `wmimgmt.msc`, and then click the **OK** button.

The Windows Management Infrastructure (WMI) dialog box appears.

3. Choose **WMI Control (Local)**, and then from the right-click menu, choose **Properties**.

The WMI Control (Local) Properties dialog box appears.

4. Choose the **Security** tab, and then click **Root** and **CIMV2** to expand the tree.

5. Click the **Security** button.

The Security for ROOT\CIMV2 dialog box appears.

Check to see if the user who connects to the monitored host or the user's group is displayed in **Group or user names**. If it is not displayed, click the **Add** button, and then add the user or the group to which the user belongs.

6. In **Group or user names**, select the user who connects to the monitored host or the group to which the user belongs.

Check to see if **Allow** is selected for both **Enable Account** and **Remote Enable**. If it is not selected, select it.

7. Click the **OK** button.

The Security for ROOT\CIMV2 dialog box closes, and the WMI Control (Local) Properties dialog box is displayed again.

8. Click the **OK** button.

The WMI Control (Local) Properties dialog box closes.

9. In the Windows Management Infrastructure (WMI) dialog box, click **File**, and then **Exit** to close the dialog box.

(4) Setting up UAC

Note the following when the OS of the monitoring target is Windows Server 2008 or later: If you specify a local user who has Administrator permissions (except for the Administrator user who is created during OS installation) as the user in monitoring target setting, UAC will restrict the permission and connection will be made as an ordinary user. Consequently, access might be refused and you might not be able to collect performance data. In this case, take one of the steps below.

(a) Specifying LocalAccountTokenFilterPolicy

You can specify the following settings only when the local host is not to be monitored:

```
reg add HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System /v  
LocalAccountTokenFilterPolicy /t REG_DWORD /d 1 /f
```

To return to the original setting, execute the following command:

```
reg delete HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies  
\System /v LocalAccountTokenFilterPolicy /f
```

(b) Disabling UAC

Specify the following settings on the PFM - RM host and the monitored hosts.

- Setting the UAC setting slider to **Never notify**
 1. Select **Control Panel**, **User Accounts**, and then **Change User Account Control settings**.
 2. Set the slider on the left-hand side of the **User Account Control Settings** window to **Never notify**.
- Setting up local security policies
 1. Select **Control Panel**, **Administrative Tools**, and then **Local Security Policy**.
 2. Select **Security Settings**, **Local Policies**, and then **Security Options**.
 3. Disable **User Account Control: Run all administrators in Admin Approval Mode**.

(5) Checking the WMI connection

Use the `wbemtest.exe` Windows tool to check whether the PFM - RM host and a monitored host are connected. Perform this procedure at the PFM - RM host.

To check the WMI connection:

1. At the command prompt, execute the following command:

```
runas /user:user-name wbemtest
```

The Windows Management Instrumentation Tester dialog box appears.

For the user name, specify the values for `RMHost_User` and `RMHost_Domain`. If re-entry of the password is requested after the command executes, specify the value of `RMHost_Password`.

For details about `RMHost_User`, `RMHost_Domain`, and `RMHost_Password`, see [Table 3-10 Instance environment setting items and values for PFM - RM for Platform \(for Windows\)](#).

To use common account information, specify the respective values that are specified in `User`, `Domain`, and `Password` in the common account information (`pfmhost`) for the instance environment.

2. Click the **Connect** button.

The Connect dialog box appears.

3. In **Namespace**, **User**, **Password**, and **Authority**, enter the appropriate information.

If the WMI connection target is the local host, there is no need to enter values in **User**, **Password**, or **Authority**. If you enter values in these items, an error occurs and you will not be able to connect.

To execute the tool (`wbemtest.exe`) on the local host, click the **Connect** button without entering values in **User**, **Password**, or **Authority**.

The following describes each item.

- **Namespace**

Enter `\\monitored-host-name\root\cimv2`. For the name of the monitored host, specify the value of Target Host.

- **User**

Enter the user name used to log on to the monitored host. For the user name, specify the value of User. To use common account information, specify the value that is specified in User in the common account information (wmi).

- **Password**

Enter the user's password. For the user's password, specify the value of Password. To use common account information, specify the value that is specified in Password in the common account information (wmi).

- **Authority**

Enter `ntlm domain: domain-name-of-monitored-host`. If the monitored host is a workgroup, leave this field blank. For the domain name of the monitored host or the monitored host name, specify the value of Domain. To use common account information, specify the value that is specified in Domain in the common account information (wmi).

For details about Target Host, User, Password, and Domain, see [Table 3-17 Setting items and values for a monitored host in PFM - RM for Platform](#).

4. Click the **Connect** button.

If connection is established successfully, the Connect dialog box closes and all buttons are enabled in the Windows Management Instrumentation Tester dialog box.

If an error dialog box is displayed, check the settings based on the error number. The error numbers and causes are described below.

Note that if you change the settings while running the `wbemtest.exe` tool, and then attempt to re-establish connection, an error might result. In such a case, restart the tool, and then check the connection.

- 0x8001011c

DCOM is not set at the PFM - RM host.

- 0x80070005

Possible cause of the error is one of the following:

- DCOM is not set at the PFM - RM host.
- DCOM is not set at the monitored host.
- The user name, password, or domain name used to connect to the monitored host is invalid.

- 0x80041003

At the monitored host, **Namespace** is not selected for WMI.

- 0x80041008

The value specified in **Authority** does not begin with `ntlm domain:.`

- 0x800706xx

Possible cause of the error is one of the following:

- The monitored host name is invalid.
- The monitored host is not running.
- The firewall was not set up at the monitored host.
- The password for the user who logs on to the monitored host has expired.

5. Click the **Enum Instances** button.

The Class Info dialog box appears.

6. To monitor processes, enter `Win32_Service` in **Enter superclass name**, or enter `Win32_PerfRawData_PerfOS_System` in all other cases, and then click the **OK** button.

The Query Result dialog box appears.

If you enter `Win32_Service` in **Enter superclass name**

Check to see if objects are displayed in the list. If an error dialog box is displayed, the user name used to connect to the monitored host might not be a member of the Administrators group.

If you enter `Win32_PerfRawData_PerfOS_System` in **Enter superclass name**

Check to see if `Win32_PerfRawData_PerfOS_System=@` is displayed in the list. If an error dialog box is displayed or this value is not displayed in the list, the user who connects to the monitored host might not be a member of the Administrators, Performance Log Users, or Performance Monitor Users group.

Note that if you change the settings while running the `wbemtest.exe` tool, and then attempt to re-execute enumeration of instances, an error might result. In such a case, restart the tool, and then re-check the connection.

For details about PFM - Manager startup, see the chapter that describes startup and termination of Performance Management in the *JPI/Performance Management User's Guide*.

3.1.6 SSH connection setting method for Windows (when the PFM - RM host is running Windows and the monitored host is running UNIX)

This subsection explains how to set up the SSH connection settings necessary for collecting performance data from a monitored host running UNIX. For SSH authentication, you use the public key authentication method.

To connect SSH, settings for the following are required:

- Enabling public key authentication for the SSH server
Specify this on the monitored host.
- Creating a key
Specify this on the PFM - RM host.
- Placing the private key on the PFM - RM host
Specify this on the PFM - RM host.
- Placing the public key on the monitored host
Specify this on the monitored host.

The following figure provides an overview of public key authentication.

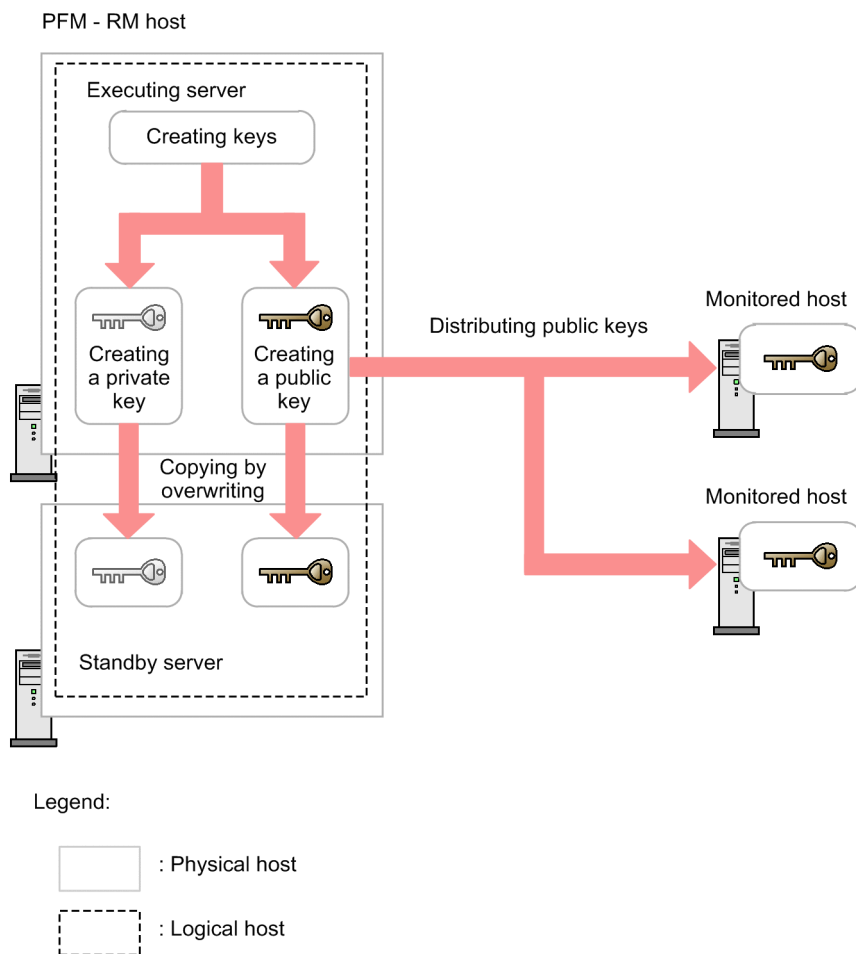

Figure 3–7: Concept of public key authentication

For public key authentication in a cluster system, you can either use a common key on both the active server node and the standby server node, or use different keys on these nodes.

To use a common key on both the active server node and the standby server node, copy the key file from the active server node to the copy file of the standby server node, overwriting any existing key files. The following figure shows the concept of using a common key.

Figure 3–8: Concept of public key authentication (when a common key is used at both the active server node and the standby server node)

To use different keys on the active server node and the standby server node, register the key files of the active server node and the standby server node at the monitored host. The following figure shows the concept of using different keys.

Figure 3–9: Concept of public key authentication (when different keys are used at the active server node and the standby server node)

(1) Enabling the SSH server's public key authentication

To enable public key authentication:

1. Log on to the monitored host as a superuser.
2. Open `/etc/ssh/sshd_config#`.
3. Change `PubkeyAuthentication` to `yes`.
4. Save and close `/etc/ssh/sshd_config#`.
5. Execute the following command to start the `sshd` service:

- For Linux 7 or SUSE Linux 12

```
[root@TargetHost.ssh]$ systemctl restart sshd.service
```

- For other OSs

```
[root@TargetHost.ssh]$ /etc/rc.d/init.d/sshd restart
```

Note

To log on as a superuser to collect information, open `/etc/ssh/sshd_config`[#] and change `PermitRootLogin` to `yes`. After that, restart the `sshd` service.

#

This will be `/opt/ssh/etc/sshd_config` when using HP-UX.

(2) Creating keys

This subsection explains the procedure for creating keys.

Log on to the PFM - RM host and create a key by executing PuTTY. You can select RSA or DSA encryption for the key type. The only difference between RSA and DSA encryption is the encryption algorithms; their operation methods are the same.

To create RSA keys:

1. From the Windows Start menu, choose **All Programs**, **PuTTY**, and then **PuTTYgen**.
The PuTTY Key Generator window appears.
2. Under **Parameters**, make sure that **SSH-2 RSA** is selected for **Type of key to generate**, and then click the **Generate** button.
A progress bar showing the key generation progress is displayed in **Key**.
Because PuTTY uses version 2 of the SSH protocol as the default, **SSH-2 RSA** is selected. For details about how to change the default used to version 1 of the SSH protocol, see the documentation for PuTTY.
3. Until the progress bar reaches 100%, randomly move the mouse in the dialog box to generate random numbers necessary for creating a key.
When the progress bar reaches 100%, the generated random numbers are displayed in **Key** and a key is generated.
4. Click the **Save private key** button to save the private key.
If you did not enter any value in **Key passphrase** or **Confirm passphrase**, a dialog box still appears. Do not enter any value in **Key passphrase** or **Confirm passphrase** and click the Yes button.
5. Click the **Save public key** button to save the public key.

(3) Placing the public key on the monitored hosts

Place the created public key on the monitored host. If there are multiple monitored hosts, distribute the key to all of them.

(a) Transferring the public key to the monitored host

Transfer the public key created at the PFM - RM host to the monitored host.

To transfer the public key:

1. Log on to the monitored host by using the value that was specified in `User` during monitoring target setup.

To use common account information, specify the value that is specified in `User` in common account information (ssh).

2. Execute the `cd` command to change the current directory to the `.ssh` directory under the home directory.

If the `.ssh` directory does not exist under the home directory, create it. For the `.ssh` directory attribute, specify 700 or 755. For the owner and group, specify the same as those specified for the user who was specified during the setup of the monitored host. If the attribute, owner, or group setting of the home directory or the `.ssh` directory is invalid, SSH connection might fail.

For details about how to specify directory attributes, see the documentation for the OS.

3. Start the command prompt at the PFM - RM host, and then change the current directory to the folder in which PuTTY is installed.

4. Execute the `pscp` command provided by PuTTY.

The following is an example of command execution when a public key is located in the PuTTY installation directory:

```
C:\Program Files\PuTTY>pscp.exe agt7.pub ClientUser@TargetHost:.ssh
ClientUser@TargetHost's password: password
agt7.pub      | 0 kB |    0.3 kB/s | ETA: 00:00:00 | 100%
```

If a message appears asking if a fingerprint should be registered, enter n.

(b) Registering the public key at the monitored host

To register the public key at the monitored host:

1. Log on to the monitored host by using the value that was specified in `User` during monitoring target setup.
To use common account information, specify the value that is specified in `User` in common account information (ssh).
2. Execute the `cd` command to change the current directory to the `.ssh` directory.
3. Execute the `ssh-keygen` command with both the `-i` and `-f` options specified.
The public key created in PuTTY is converted into a format that can be used by OpenSSH.
4. Execute the `rm` command to delete the public key file received in [\(a\) Transferring the public key to the monitored host](#).
5. Execute the `chmod` command to change the attribute of the authentication key file to 600.

An example of performing steps 2 through 5 follows:

```
[ClientUser@TargetHost ~]$ cd .ssh
[ClientUser@TargetHost .ssh]$ ssh-keygen -i -f agt7.pub >> authorized_keys
[ClientUser@TargetHost .ssh]$ rm agt7.pub
[ClientUser@TargetHost .ssh]$ chmod 600 authorized_keys
```

The name of the authentication key file is set by `AuthorizedKeysFile` of `/etc/ssh/sshd_config`. For HP-UX, it is `/opt/ssh/etc/sshd_config`.

By default, `~/.ssh/authorized_keys` is set.

(4) Checking the connection and registering a fingerprint

To check whether the PFM - RM host and a monitored host can connect to each other:

1. Log on to the PFM - RM host by using the value that was specified in `RMHost_User` during instance environment setup.

To use common account information, log on to the PFM - RM host by using the value that is specified in `User` in common account information (`pfmhost`).

2. Start the command prompt.

3. Using the created private key, execute PuTTY's `plink` command on the monitored host.

The connection process begins.

4. During the initial connection, register a fingerprint.

Register the fingerprint of the public key on the monitored host. Here, enter `y`. When you enter `y`, the monitored host's command prompt appears.

5. From the monitored host's prompt, execute the `exit` command to log out from the monitored host.

6. From the PFM - RM host, execute PuTTY's `plink` command on the monitored host to reconnect to it.

If the monitored host's prompt appears in subsequent connections without you having to enter any information, setup of the connection between the PFM - RM host and the monitored host is completed. From the monitored host's command prompt, execute the `exit` command to log out from the monitored host.

If an error occurs or if you are asked to enter anything, check to see if you have correctly followed the procedure.

A setting example for checking connection follows:

```
C:\WINDOWS\system32>"C:\Program Files\PuTTY\plink.exe" -ssh -noagent -i "C:\Program Files\PuTTY\agt7.ppk" -P 22 ClientUser@TargetHost
The server's host key is not cached in the registry. You
have no guarantee that the server is the computer you
think it is.
The server's rsa2 key fingerprint is:
ssh-rsa 2048 xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx
If you trust this host, enter "y" to add the key to
PuTTY's cache and carry on connecting.
If you want to carry on connecting just once, without
adding the key to the cache, enter "n".
If you do not trust this host, press Return to abandon the
connection.
Store key in cache? (y/n) y

Notes:

- PFM - RM for Platform assumes that fingerprint registration has already been completed. Because you can register a fingerprint during the initial SSH client connection, we recommend that you complete the procedure described here at that point.
- If you change the user account specified for `RMHost_User` during the instance environment setup, you need to re-register a fingerprint. If you are using common account information, you also need to re-register a fingerprint when updating the value of `User` in common account information (`pfmhost`).
- If you run PFM - RM for Platform in a cluster system, register a fingerprint on the standby node in the same way as on the executing node.
- Confirm that a response is returned in less than 10 seconds when you execute a command such as `uname` on the monitored host from the PFM - RM host.

For details about PFM - Manager startup, see the chapter that describes startup and termination of Performance Management in the *JPI/Performance Management User's Guide*.

3.1.7 Notes about installation and setup of the Windows edition

This subsection provides notes about installing and setting up Performance Management in a Windows environment.

(1) Notes about registry

PFM - RM for Platform supports operation in an environment that is set up by the OS-provided standard method. If you have customized the OS environment, such as by using a registry editor to directly edit registry information, performance data might no longer be collected correctly even if such customization is disclosed in the Microsoft technical support information.

(2) Notes about environment variables

Performance Management uses the `JPC_HOSTNAME` environment variable. Do not set a user-specific `JPC_HOSTNAME` environment variable. If such an environment variable is set, Performance Management will not function correctly.

(3) Notes about installing multiple Performance Management programs on the same host (for Windows)

In Performance Management, you can install PFM - Manager, PFM - Web Console, and PFM - RM for Platform on the same host. This subsection provides notes about installing multiple Performance Management programs on the same host.

To improve system performance and reliability, we recommend that you run PFM - Manager, PFM - Web Console, and PFM - RM for Platform on separate hosts.

- PFM - Manager and PFM - Base cannot be installed on the same host. If you need to install PFM - Manager on a host where PFM - Base and PFM - RM for Platform have been installed, perform the following procedure:
 1. Uninstall all Performance Management programs except PFM - Web Console.
 2. Install PFM - Manager.
 3. Install PFM - RM for Platform.
- If you need to install PFM - Base on a host where PFM - Manager and PFM - RM for Platform have been installed, perform the following procedure:

1. Uninstall all Performance Management programs except PFM - Web Console.
 2. Install PFM - Base.
 3. Install PFM - RM for Platform.
- If you are installing PFM - RM for Platform on the PFM - Web Console host, close all browser windows before you start the installation.
 - If you install a new Performance Management program, the status management function is enabled by default.

(4) Notes about upgrading (for Windows)

For notes about upgrading the Performance Management programs, see the section that presents notes about upgrading in the chapter describing installation and setup in the *JP1/Performance Management Planning and Configuration Guide*.

For notes about upgrading PFM - RM for Platform, see [G. Migration Procedure and Notes on Migration](#).

For details about upgrading, see the relevant Appendix in the *JP1/Performance Management Planning and Configuration Guide*.

(5) Notes about installing PFM - RM for Platform in a Windows environment

This subsection provides notes about installing PFM - RM for Platform in a Windows environment.

- If you install PFM - RM for Platform in an environment where no Performance Management program has been installed, make sure that there are no folders or files in the installation folder.
- If you install PFM - RM for Platform while Performance Management programs and services or other programs that reference Performance Management files (such as Windows Event Viewer) are running, a message prompting you to restart the system might be displayed. In such a case, restart the system according to the message to complete the installation.
- If you install PFM - RM for Platform in any of the statuses below, file expansion might fail:
 - Performance Management programs and services or other programs that reference Performance Management files (such as Windows Event Viewer) are running.
 - The disk capacity is insufficient.
 - The user does not have required folder permissions.

If installation has failed, terminate the programs that reference Performance Management files or take appropriate action, such as by resolving the problem of insufficient disk capacity or of folder permissions, and then re-install PFM - RM for Platform.

- If you upgrade PFM - RM for Platform in a cluster environment, you must place the shared disk online in either the executing system or the standby system.
- If you perform new installation of PFM - RM for Platform, the system must be restarted. In the case of overwrite installation and upgrading, a message prompting the user to restart the system might be displayed. In such a case, restart the system according to the message to complete the installation.
- If the *installation-folder\setup* folder contains the setup file of PFM - RM for Platform, additional setup of a new PFM - RM for Platform will be executed.
- Before you install a Performance Management program, check to see if any of the security-related programs described below are installed. If such a program is installed, take appropriate action according to the information provided below.
 - Security monitoring program

Either terminate the security monitoring program or change its settings so that installation of the Performance Management program will not be affected.

- Virus detection program

We recommend that you terminate any virus detection program before you install the Performance Management programs.

If a virus detection program is running during installation of a Performance Management program, it might slow down the installation process, the installation might fail, or the program might not install correctly.

- Process monitoring program

Either terminate the process monitoring program or change its settings so that it does not monitor Performance Management services and processes or services and processes of common components.

Installation of a Performance Management program might fail if these services and processes are started or stopped by the process monitoring program during the installation process.

3.2 Installation and setup of the UNIX edition

This section describes the procedures for installing and setting up PFM - RM for Platform in a UNIX environment.

3.2.1 Issues to consider before installing the UNIX edition

This subsection describes issues to be considered before you install PFM - RM for Platform.

(1) Prerequisite OS

PFM - RM for Platform runs on Linux.

(2) Setting up a network environment

To use Performance Management to run PFM - RM for Platform, you must set up a network environment, such as IP addresses and port numbers.

(a) Setting IP addresses

You must set up the environment for PFM - RM for Platform in such a manner that an IP address can be determined from the host name. PFM - RM for Platform will not start in an environment in which IP addresses cannot be resolved.

You use one of the following methods to set host names and IP addresses:

- `jpchosts` file (Performance Management's host information configuration file)
- `hosts` file
- DNS

For the monitoring host name, use either the real host name or the alias name.

- Using the real host name

In a UNIX environment, specify the name in such a manner that the IP address can be resolved from the host name that is obtained from the result of executing the `uname -n` command. You can also use the host name that is acquired by the `hostname` command.

Note that Performance Management supports DNS, but not FQDN. This means that when you set the IP address, you must use the host name obtained by the `uname -n` command without the domain name.

- Using an alias name

Set the environment in such a manner that the IP address can be resolved from the specified alias name.

For details about setting the name of the monitoring host, see the chapter that describes changing the system configuration in the *JPI/Performance Management Planning and Configuration Guide*.

Note that the IP address specified in the `jpchosts` file is not used for IP address resolution with the monitored host.

Notes about setting IP addresses

- If you use Performance Management in multiple LAN environments, use the `jpchosts` file to set IP addresses. For details about using the `jpchosts` file to set IP addresses, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

- Performance Management will not run on a host where IP addresses are assigned dynamically by DHCP. You must set fixed IP addresses for all monitoring hosts.

(b) Settings for using IPv6

Performance Management supports both IPv4 and IPv6 network environments. Therefore, you can run Performance Management even in a network environment where IPv4 and IPv6 coexist.

PFM - RM for Platform can use IPv6 to communicate with PFM - Manager. However, this applies only when the OS of the host on which PFM - RM for Platform and PFM - Manager are installed is Windows or Linux. For details about the applicable scope of communication in the IPv4 and IPv6 environments, see [L. Communication in IPv4 and IPv6 Environments](#).

To communicate using IPv6, you must enable the use of IPv6 on both the PFM - Manager host and the PFM - RM host. Before installing PFM - RM for Platform, you must also enable the use of IPv6 on the PFM - RM host. To configure this setting, execute the `jpcconf ipv6 enable` command. If the use of IPv6 is already enabled, there is no need to configure this setting. To check whether the use of IPv6 is enabled, execute the `jpcconf ipv6 display` command.

For details about the `jpcconf ipv6 enable` and `jpcconf ipv6 display` commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*. For details about the conditions and timing for executing the `jpcconf ipv6 enable` command, see the chapter that describes an example of a network configuration that includes an IPv6 environment in the *JPI/Performance Management Planning and Configuration Guide*.

When PFM - RM for Platform will use IPv6 to communicate with monitored hosts, specify a monitored host name that can be resolved.

PFM - RM for Platform uses a resolvable IP address to communicate with a monitoring target. When PFM - RM for Platform communicates with a monitoring target in an environment where IPv4 and IPv6 coexist, PFM - RM for Platform will not try to communicate using another IP address if communication using a resolvable IP address fails.

For example, if a connection attempt using IPv4 fails, PFM - RM for Platform will not retry using IPv6. Conversely, if a connection attempt using IPv6 fails, PFM - RM for Platform will not retry using IPv4. Therefore, make sure that connection can be established beforehand.

(c) Setting port numbers

You must assign a port number to each service of the programs used in Performance Management. Set up the network in such a manner that the port numbers assigned to PFM - RM for Platform can be used for communication.

The table below lists and describes the default port numbers assigned to various services. For other services, an unused port number is assigned automatically each time the service starts.

Table 3–20: Default port numbers for services (for Windows)

No.	Supported function	Service name	Parameter	Port number	Description
1	Service configuration information management function	Name Server	<code>jplpcnsvr</code>	22285	Port number used by PFM - Manager's Name Server service. This port number is set at all hosts of Performance Management.
2	Service status management function	Status Server	<code>jplpcstatsvr</code>	22350	Port number used by the Status Server service of PFM - Manager and PFM - Base.

No.	Supported function	Service name	Parameter	Port number	Description
2	Service status management function	Status Server	jplpcstatsvr	22350	This port number is set at the host where PFM - Manager and PFM - Base are installed.
3	Monitoring console communication function	View Server	jplpcvsvr	22286	Port number used by the View Server service of PFM - Manager. This port number is set at the host where PFM - Manager is installed.
4	Web service function	Web Service	--	20358	Port number used by the Web Service service of PFM - Web Console.
5	Web container function	Web Console	--	20359 20360	Port number used by the Web Console service of PFM - Web Console.
6	JP1/SLM linkage facility	JP1/ITSML	--	20905	Default port number specified in JP1/SLM.

Legend:

--: Not applicable

When you use Performance Management in an environment that includes a firewall, you must use fixed port numbers. For details about how to use fixed port numbers, see the chapter that describes installation and setup in the *JP1/Performance Management Planning and Configuration Guide*.

(3) OS user permissions required for installation

When you install PFM - RM for Platform, make sure that you use an account that has Administrator permissions.

(4) Prerequisite programs

This subsection describes the configuration of programs required in order to install PFM - RM for Platform.

There are two major types of program configurations, as described below. Evaluate the program configurations from the perspective of your system environment.

When installing PFM - RM for Platform on the PFM - Manager host

With this program configuration, PFM - RM for Platform is installed on the same host as PFM - Manager. The following figure shows the program configuration.

Figure 3–10: Program configuration (when PFM - RM for Platform and PFM - Manager are installed on the same host (for UNIX))

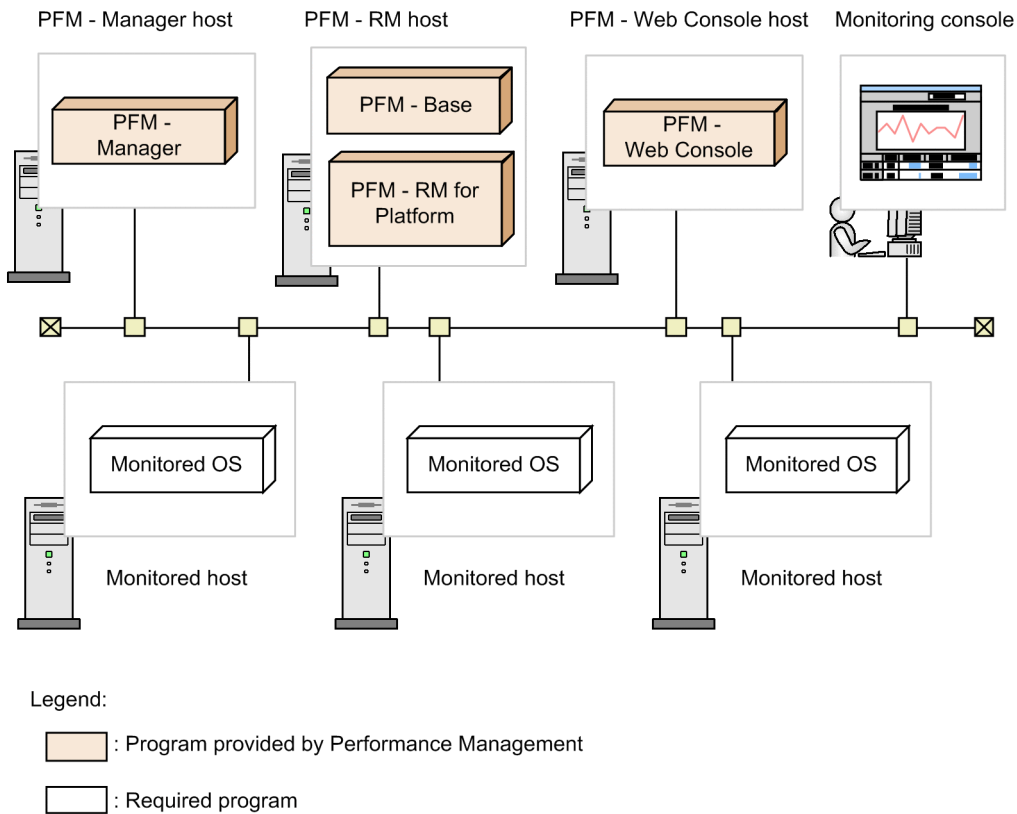

Legend:

- : Program provided by Performance Management
- : Required program

When installing PFM - RM for Platform on a host other than the PFM - Manager host

With this program configuration, PFM - RM for Platform is installed on a host other than the PFM - Manager host. If you use this program configuration, you must install PFM - Base on the same host as for PFM - RM for Platform. The following figure shows the program configuration.

Figure 3–11: Program configuration (when PFM - RM for Platform and PFM - Base are on the same host (for UNIX))

(a) Prerequisite OSs for monitored hosts

A monitored host must be using one of the following OSs:

- HP-UX
- Solaris
- AIX
- Linux

Note that health check monitoring can monitor hosts and hardware equipment, even not running the prerequisite OSs listed above, that support the ICMP protocol (can communicate through `ping` command).

(b) Prerequisite programs for Performance Management

PFM - Manager or PFM - Base must be available on the host where PFM - RM for Platform is installed.

If you install PFM - RM for Platform on a host where PFM - Manager is available, PFM - Base is not required. If you install multiple PFM - RMs on a host where PFM - Base is available, you need only one PFM - Base.

You also need PFM - Web Console in order to use PFM - RM for Platform to monitor the operation of monitored hosts.

(5) Environment settings required for collecting performance data (for UNIX)

PFM - RM for Platform uses SSH to collect performance data from monitored hosts. Performance data cannot be collected if SSH connection settings have not been specified. Because SSH authentication uses the public key

authentication method, you must specify public key authentication settings. You might need to install other appropriate packages because OS commands are used to collect performance data.

The following describes the required SSH settings.

(a) Installing packages

■ RPM packages required for the PFM - RM host

For details about the RPM packages required for the PFM - RM host, see the *Release Notes* for this product.

■ Packages required for monitored hosts (SSH)

The packages (SSH) required for a monitored host depend on the OS of the monitored host. For details, see the *Release Notes* for this product.

■ Packages required for monitored hosts (commands)

For details about the packages required for monitored hosts (commands), see [3.1.1\(6\)\(b\) Installing software and packages](#).

(b) SSH connection settings

Specify the SSH connection settings at both the PFM - RM host and the monitored hosts. For details about the SSH connection settings, see [3.2.5 SSH \(for UNIX\) connection setting method](#).

(c) User of a monitored host

If the OS of a monitored host is AIX and a user other than `root` is to collect information, that user must belong to both the `adm` group and the `system` group; otherwise, some information will not be collected.

To ensure that the user belongs to both groups (`adm` and `system`), execute the following command at the connection-target monitored host:

```
$ id
uid=xxx(xxx) gid=x(xxx) groups=0(system),4(adm)
```

For details about the information that will not be collected, see [7. Records](#). If the OS of the monitored host is not AIX, this user limitation is not applicable.

(6) Environment settings required for monitoring the operating status (when health check monitoring is used)

To use health check monitoring, the health check function must be set up so that it can monitor the operating statuses of monitored hosts. The following describes the required health check monitoring settings.

(a) Setting the connection-target PFM - Manager

The health check function must be enabled on the connection-target PFM - Manager.

For details about the setting method of the health check function, see the chapter that describes the settings of the health check function in the *JPI/Performance Management User's Guide*.

(b) Setting at the PFM - RM host

The PFM - RM host must have the following settings enabled:

- Status management function

For details about the setting method of the status management function, see the chapter that describes the settings of the status management function in the *JP1/Performance Management User's Guide*.

- Monitored host polling

Set the `Health Check for Target Hosts` property for the Remote Monitor Collector service of PFM - RM for Platform to `Yes`.

(c) Setting health check monitoring

Set the `TargetType` property for the PFM - RM for Platform remote agent to `icmp`. Health check monitoring can monitor the operating statuses of hosts and hardware equipment that support the ICMP protocol (can communicate through `ping` command).

For details about the settings of health check monitoring, see [3.2.4\(4\) Setting the monitored host](#).

(7) Prerequisite when setting the process operation monitoring condition to 4,096 bytes

When using version 10-00 or later of PFM - Manager and PFM - Web Console, you can set the monitoring condition to be used for monitoring performance to a maximum of 4,096 bytes.

When installing PFM - Base or PFM - Manager on the PFM - RM host, use version 10-00 or later.

(8) Preparing to collect information when an error occurs

If a problem occurs, you might have to collect core dump files as information to be used for investigating the problem. Because the output of core dump files depends on the user's environment settings, check the following settings:

Core dump file size setting

The maximum size of core dump files is limited by the root user's core dump file size setting (`ulimit -c`). Set up a script as follows:

```
ulimit -c unlimited
```

If this setting violates the security policy of the machine being used, turn the script setting into a comment line as shown in the following:

```
# ulimit -c unlimited
```

Important

When you turn the script setting into a comment, the core dump will not be output when a trigger for outputting a core dump file occurs, such as when a segmentation error or bus error occurs in a process. Consequently, you might not be able to investigate the cause of the error.

Kernel parameter setting related to core dump (Linux only)

If you change the output destination for the core dump files and their file names from the default settings by using Linux kernel parameter (`kernel.core_pattern`), you might not be able to collect the core dump files.

Therefore, we recommend that you do not change the Linux kernel parameter (`kernel.core_pattern`) settings.

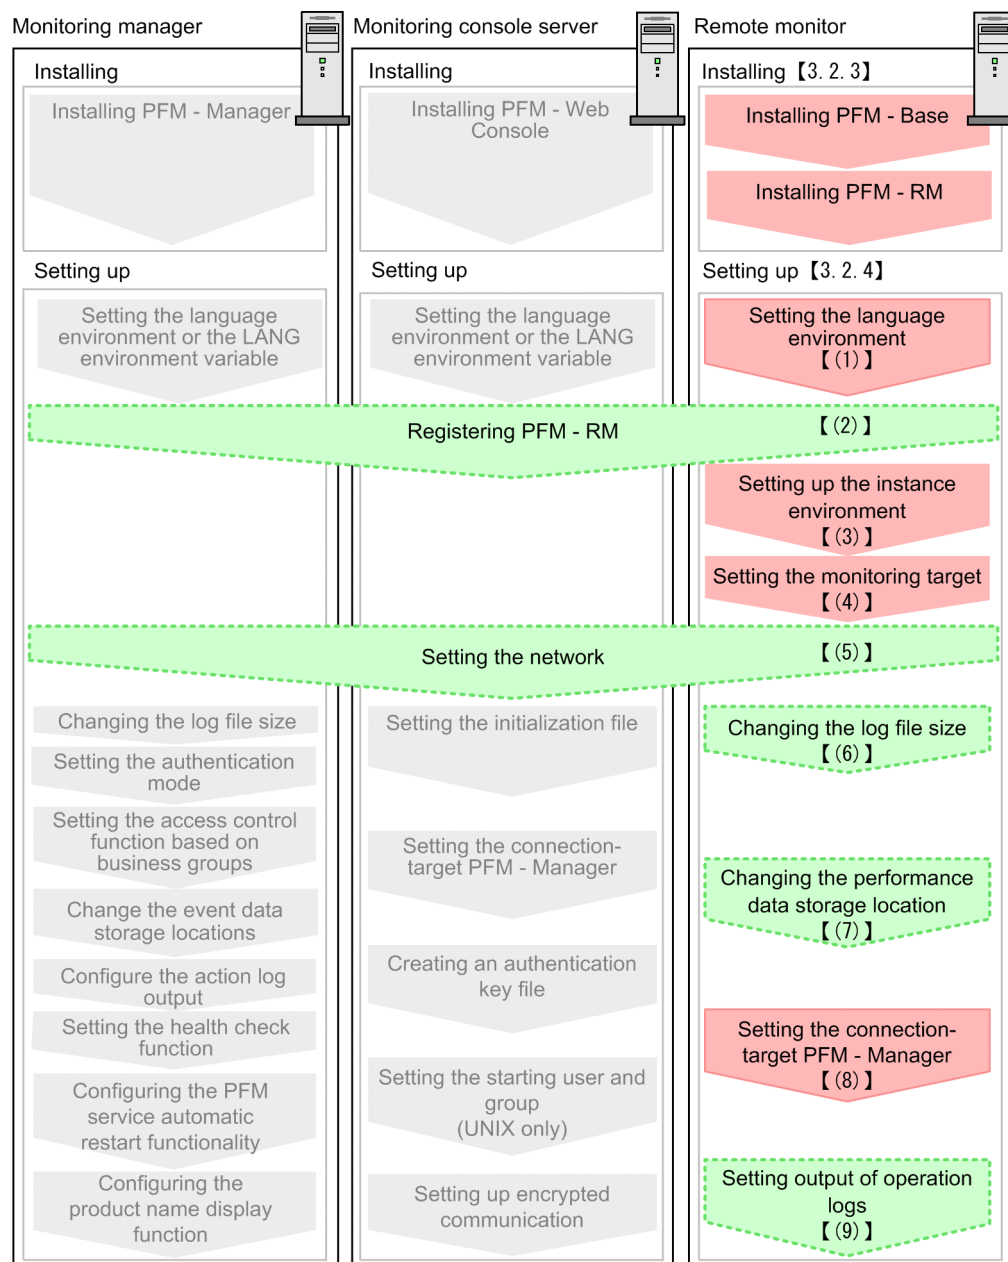

3.2.2 Flow of installation and setup for the UNIX edition

This subsection describes the procedures for installing and setting up PFM - RM for Platform.

For details about how to install and set up PFM - Manager and PFM - Web Console, see the chapter that describes installation and setup in the *JP1/Performance Management Planning and Configuration Guide*.

The following figure shows the procedures for installing and setting up PFM - RM for Platform.

Figure 3–12: Installation and setup procedures (for UNIX)

For setup commands that require a user input, you can select whether to execute the commands in the interactive or non-interactive mode.

When a command is executed in the interactive mode, the user must enter values by following the instruction displayed by the command.

When a command is executed in the non-interactive mode, no user input is required because option specifications or definition files replaces the input steps required during command execution. Furthermore, batch processing or remote execution can automate the setup procedure, thereby reducing the workload on the administrator and the cost of operations. Commands in the non-interactive mode are convenient in the following cases:

- You want to change the password used for connecting to monitoring targets on a regular basis.
- You want to improve the efficiency of the procedure for adding multiple monitoring targets.

For details about commands, see the manual *JP1/Performance Management Reference*.

3.2.3 Installation procedure for the UNIX edition

This subsection describes how to install PFM - RM for Platform in a UNIX environment.

(1) Program installation sequence

This subsection describes the order in which PFM - RM for Platform and its prerequisite programs are to be installed.

When installing PFM - RM for Platform on the PFM - Manager host

Install PFM - Manager first, and then install PFM - RM for Platform.

Figure 3–13: Program installation sequence (when PFM - RM for Platform and PFM - Manager are on the same host (for UNIX))

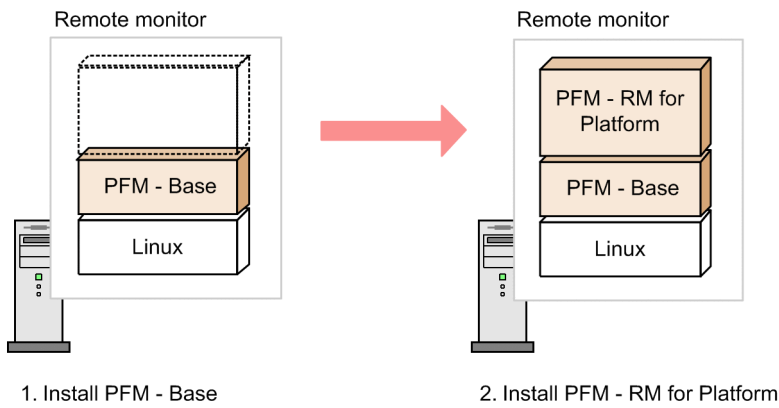

Legend:

- : Program provided by Performance Management
- : Required program

When installing PFM - RM for Platform on a host other than the PFM - Manager host

Install PFM - Base first, and then install PFM - RM for Platform.

Figure 3–14: Program installation sequence (when PFM - RM for Platform and PFM - Base are on the same host (for UNIX))

Legend:

- : Program provided by Performance Management
- : Required program

If you install multiple PFM - RMs on the same host, you can install the individual PFM - RMs in any order.

(2) Installation procedure

This subsection describes how to install PFM - RM for Platform.

There are two ways to install PFM - RM for Platform in a UNIX environment: by using the distribution media or by using JPI/Software Distribution for remote installation. For details about the method that uses JPI/Software Distribution, see the *Job Management Partner 1/Software Distribution Manager, Job Management Partner 1/Software Distribution SubManager Description and Administrator's Guide* (for UNIX systems), and *Job Management Partner 1/Software Distribution Client Description and User's Guide* (for UNIX systems).

! Important

Depending on the machine environment, directory and file names might differ from those indicated in the manuals. Use the `ls` command to check the correct directory and file names in your environment. When you execute the command that starts Hitachi PP Installer, specify the directory and file names displayed by the `ls` command.

To install from the distribution media:

1. At the host where the program is to be installed, log in as a superuser. Alternatively, use the `su` command to change the user to a superuser.
2. Stop any Performance Management services running on the local host.
You must stop all Performance Management services running on physical and logical hosts. For details about how to stop services, see the chapter that describes starting and stopping Performance Management in the *JPI/Performance Management User's Guide*.
3. Insert the distribution media into the appropriate drive.
4. Execute the `mount` command to mount the distribution media.

The following example mounts the distribution media in the mount directory:

```
/bin/mount -r -o mode=0544 device-special-file-name mount-directory
```

5. Execute the following command to start the Hitachi Program Product Installer:

```
mount-directory/X64LIN/SETUP mount-directory
```

The Hitachi Program Product Installer starts and the initial window is displayed.

6. In the initial window, enter 1.

A list of the programs that can be installed is displayed.

7. Select PFM - RM for Platform, and then enter 1.

PFM - RM for Platform is installed. To select another program, move the cursor to the desired program, and then press the space key to select it.

8. When installation is completed successfully, enter Q.

The initial window of the Hitachi Program Product Installer is displayed again.

3.2.4 Setup procedure for the UNIX edition

This subsection describes how to set up PFM - RM for Platform.

 indicates the following setup items:

- Setup item required depending on the environment in use
- Setup item for changing a default setting

(1) Setting the LANG environment variable

You must set the LANG environment variable.

Before you set a LANG environment variable value, check that the applicable language environment has been installed and configured correctly. Invalid installation and configuration of the language environment might result in encoding errors and illegal rewriting of definition data.

The table below shows the LANG environment variable values supported by PFM - RM for Platform. If you specify any language other than those shown in the table (such as German, French, Spanish, Korean, or Russian), the system will assume that the LANG environment variable is set to C.

Table 3–21: LANG environment variable values supported by PFM - RM for Platform

No.	Language	Character encoding	LANG environment variable value
1	Japanese	Shift_JIS(SJIS)	<ul style="list-style-type: none">• ja_JP.SJIS#• ja_JP.sjis#
2		UTF-8 code	<ul style="list-style-type: none">• ja_JP.UTF-8• ja_JP.utf8
3	English	ASCII	C

No.	Language	Character encoding	LANG environment variable value
4	Chinese (simplified characters)	GB18030	• zh_CN.gb18030
5		UTF-8	• zh_CN.UTF-8 • zh_CN.utf8

#: These values can be used for only SUSE Linux.

Notes regarding setting of the LANG environment variable

The language for the common message log is determined by the LANG environment variable that is specified during service startup or command execution. Therefore, character strings in multiple language codes, such as both Japanese and English, might be present.

(2) Registering PFM - RM for Platform

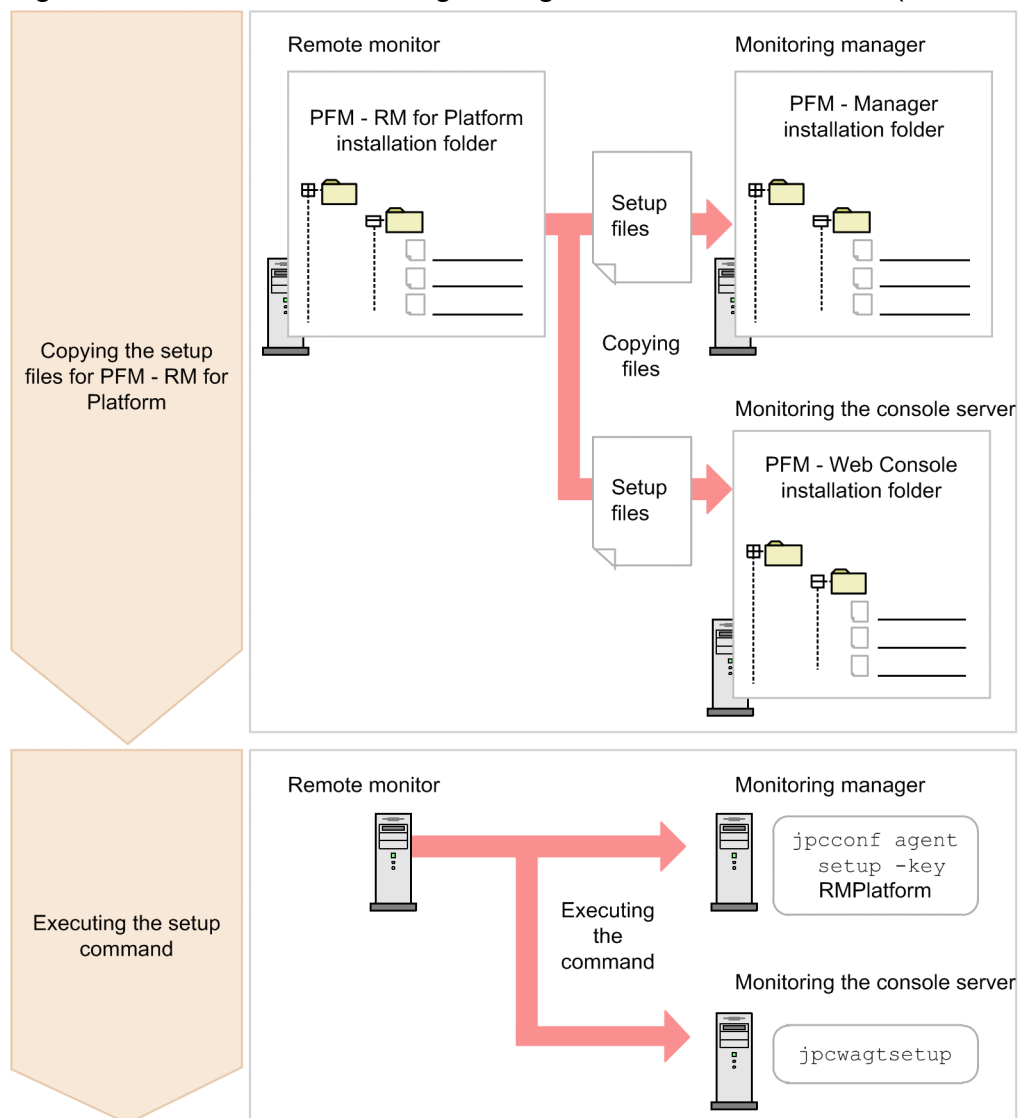

To achieve central management of PFM - RM for Platform in the Performance Management system, you must register PFM - RM for Platform into PFM - Manager and PFM - Web Console.

You must register PFM - RM for Platform at the following times:

- Whenever you add a new PFM - RM for Platform in the Performance Management system.
Note: If a PFM - RM for Platform has already been registered and you are adding a new PFM - RM for Platform of the same version, there is no need to register the new PFM - RM for Platform.
- When you update the Data model version for the registered PFM - RM for Platform.

The following figure shows the procedure for registering PFM - RM for Platform.

Figure 3–15: Procedure for registering PFM - RM for Platform (for UNIX)

Notes about registering PFM - RM for Platform

- Register PFM - RM for Platform before you set up an instance environment.
- If you install different versions of PFM - RM for Platform on separate hosts, set up old versions before you set up new versions.
- If you install PFM - RM for Platform on the same host as where PFM - Manager is installed, the `jpccconf agent setup` command executes automatically.
- When PFM - RM for Platform is registered, folders named `RMPlatform` are created on the **Reports** and **Alarms** pages of PFM - Web Console. If you have already created a folder or file named `RMPlatform` on the **Reports** page, you must rename it before starting the registration procedure.

The following subsections describe how to register PFM - RM for Platform.

(a) Copying the setup files for PFM - RM for Platform

Copy the setup files from the PFM - RM host to the hosts where PFM - Manager and PFM - Web Console are installed.

To copy the setup files:

1. Stop PFM - Web Console.

If PFM - Web Console is running, stop it.

2. Copy the setup files in binary mode.

Copy the files from the PFM - RM host to the PFM - Manager and PFM - Web Console hosts.

The following table lists the source file storage locations and the copy destination locations.

Table 3–22: Setup files to be copied (for UNIX))

No.	Source (setup files for PFM - RM for Platform)	Target		
		Program name	OS	Target folder
1	/opt/jplpc/setup/jpcagt7w.EXE	PFM - Manager	Windows	<i>PFM-Manager-installation-folder\setup</i>
2	/opt/jplpc/setup/jpcagt7u.Z		UNIX	/opt/jplpc/setup/
3	/opt/jplpc/setup/jpcagt7w.EXE	PFM - Web Console	Windows	<i>PFM-Web-Console-installation-folder\setup</i>
4	/opt/jplpc/setup/jpcagt7u.Z		UNIX	/opt/jplpcwebcon/setup/

(b) Executing the setup command at the PFM - Manager host

At the PFM - Manager host, execute the setup command for PFM - RM for Platform.

Execute the following command:

```
jpcconf agent setup -key RMPlatform
```

This example shows execution in the interactive mode, but you can also execute the `jpcconf agent setup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

Notes about executing the command

Before you execute the command, stop all Performance Management programs and services at the local host. An error might occur if the `jpcconf agent setup` command is executed before all Performance Management programs and services have stopped completely. If an error has occurred, make sure that all Performance Management programs and services have stopped completely, and then re-execute the `jpcconf agent setup` command.

After you have executed the setup command at the PFM - Manager host, you might delete the setup files for PFM - RM for Platform that were copied to the PFM - Manager.

(c) Executing the setup command at the PFM - Web Console host

At the PFM - Web Console host, execute the setup command for PFM - RM for Platform.

Execute the following command:

```
jpcwagtsetup
```

After you have executed the setup command at the PFM - Web Console host, you might delete the setup files for PFM - RM for Platform that were copied to the PFM - Web Console.

(3) Setting up an instance environment

Set up an instance environment for PFM - RM for Platform at the PFM - RM host. To set multiple instance environments, repeat this procedure. In PFM - RM for Platform, you can define a maximum of 50 monitoring targets in a single instance environment.

Notes about setting instance environments

Before you set instance environments, make sure that the procedure described in [3.2.1\(5\) Environment settings required for collecting performance data \(for UNIX\)](#) has been completed and the correct environment has been set up.

(a) Instance environment setting items that must be specified depending on what is monitored in the instance

The instance environment setting items that must be specified differ depending on what is monitored in the instance. The following table lists and describes the instance environment setting items that must be specified for each monitoring target in the instance.

Table 3–23: Instance environment setting items that must be specified for each monitoring target in the instance

Item name	What is monitored in the instance	
	UNIX environment	Health check monitoring
Interval	D	T
Std_Category	D	T
Disk_Category	D	T
Network_Category	D	T
Ps_Category	D	T
Log_Size	D	D

Legend:

D: Specification is required if the default value is to be changed.

T: There is no need to change the default value.

(b) Instance environment setting items and values

The table below lists and describes the instance environment setting items and values. Check this information before you start operations.

Use the `jpccnf inst setup` command to set up an instance environment. For details about how to execute the `jpccnf inst setup` command, see [\(c\) Execution in the interactive mode](#) and [\(d\) Execution in the non-interactive mode](#).

Table 3–24: Instance environment setting items and values for PFM - RM for Platform (for UNIX)

No.	Item name ^{#1}	Description	Setting	Default
1	Interval	Specifies a collection interval for the collection process.	Specify a value in the range from 60 to 3,600 (seconds).	300

No.	Item name ^{#1}	Description	Setting	Default
2	Std_Category ^{#2}	Specifies whether the collection process is to collect basic information (PI and PI_CPU records).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	Y
3	Disk_Category ^{#2}	Specifies whether the collection process is to collect disk information (PI_PDSK and PI_LDSK records).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	Y
4	Network_Category ^{#2}	Specifies whether the collection process is to collect network information (PI_NET record).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	Y
5	Ps_Category ^{#2}	Specifies whether the collection process is to collect process information (PD_APS, PD_ASVC, PD_APP2, PD_APPC, and PD_APPD records).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	Y
6	Log_Size	Specifies the maximum size of one agent log file. ^{#3}	Specify a value in the range from 1 to 32 (megabytes).	3

#1

When the `jpccnf inst setup` command is executed in the non-interactive mode, this item name is used as a product-specific label in the definition file. For details about commands in the non-interactive mode, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

#2

The settings for `Std_Category`, `Disk_Category`, `Network_Category`, and `Ps_Category` are given higher priority than the collection settings for the individual records.

For example, if you set `Std_Category` to N (do not collect), a PI record is handled as follows:

- The PI record information is not recorded in the Store database.
- If an attempt is made to display a real-time report based on PI records, the KAVJS5001-I error message is displayed.
- If an alarm is bound to a PI record, that alarm will not function.

#3

The following formula can be used to estimate the agent log file size:

Agent log (megabytes) = $((a \times 24 \times 3600) \div b \times 4) \div (4 \times 1024)$

Legend:

a: Number of days agent logs are stored

b: Interval value of the instance

For agent logs, the maximum number of files collected for each instance is (8 + the number of monitoring targets × 4). If there is not enough free space on the hard disk, agent logs result in an output error. For details about agent logs, see [9.3 Log information to be collected for troubleshooting](#).

(c) Execution in the interactive mode

1. Execute the `jpccnf inst setup` command.

The command sets an instance environment with an instance name of `inst1`:

```
jpccnf inst setup -key RMPlatform -inst inst1
```

2. Set up an instance environment for PFM - RM for Platform.

Enter each instance environment setting for PFM - RM for Platform according to the command's instructions. For details about each instance environment setting, see [Table 3-24 Instance environment settings for PFM - RM for](#)

Platform (for UNIX). After you enter each setting, press the **Enter** key. To use a displayed default value, press the **Enter** key.

The following example sets all instance environment settings to the default values:

```
/opt/jp1pc/tools>jpcconf inst setup -key RMPlatform -inst inst1
Interval                [300]                :<Enter>
Std_Category            [Y]                  :<Enter>
Disk_Category           [Y]                  :<Enter>
Network_Category        [Y]                  :<Enter>
Ps_Category             [Y]                  :<Enter>
Log_Size (MB)           [3]                  :<Enter>
KAVE05080-I The instance environment is now being created.
(servicekey#=RMPlatform, inst=inst1)
KAVE05081-I The instance environment has been created.
(servicekey#=RMPlatform, inst=inst1)
```

#

If PFM - Manager's product name display function is disabled, agt7 is displayed for servicekey.

(d) Execution in the non-interactive mode

1. Execute the `jpcconf inst setup` command to create a definition file template.

Execute the command as follows:

```
jpcconf inst setup -key RMPlatform -noquery -template definition-file-name
```

Sections and labels that correspond to the instance environment settings are output to a definition file. Note that the value for the label of the Instance Definitions section is left blank.

2. Edit the definition file template created in step 1.

Edit the template setting values according to the instance environment.

For details about the product-specific labels to be specified in the definition file, see [Table 3-24 Instance environment settings for PFM - RM for Platform \(for UNIX\)](#).

Shown below is an example of coding a definition file. Specify values for the labels in the Instance Definitions section according to the instance environment.

```
[Common Definitions]
Definition File Version=0001

[Product Information]
Product ID=7

[Instance Definitions]
Interval=300
Std_Category=Y
Disk_Category=Y
Network_Category=Y
Ps_Category=Y
Log_Size=3
```

3. Execute the `jpcconf inst setup` command to set up the instance environment for PFM - RM for Platform.

Shown below is an example of executing a command for setting up an instance environment where `inst1` is the instance name. For the `-input` option, specify the definition file edited in step 2.

```
jpcconf inst setup -key RMPlatform -inst inst1 -noquery -input definition-  
file-name
```

Note;

If the definition file contains confidential information such as passwords, save the definition file in a secure location, and delete it after you have used it. If you want to transfer the definition file between hosts, we recommend that you use a secure file transfer protocol, such as Secure File Transfer Protocol (SFTP), which is FTP over an SSH tunnel.

When all of the settings have been completed, an instance environment can be built. The following table shows the directory structure of an instance environment.

Table 3–25: Directory structure of an instance environment (for UNIX)

No.	Storage directory	File name	Description
1	/opt ^{#1} /jplpc/agt7/agent/ <i>instance-name</i>	jpcagt.ini	Service startup initialization file of Remote Monitor Collector
2		jpcagt.ini.lock	Lock file for the service startup initialization file of Remote Monitor Collector (for each instance)
3		jpcagt.ini.model ^{#2}	Sample of a service startup initialization file of Remote Monitor Collector
4		status.dat	Intermediate file for internal processing
5		tstatus.dat	Virtual Agent status information ^{#3}
6		targetlist.ini	List of monitoring targets
7		grouplist.ini	List of groups
8		GARULES.DAT	Grouping rule description file
9		targets	Storage folder for remote agent
10		groups	Storage folder for group agent
11		log	Storage folder for log files
12	/opt ^{#1} /jplpc/agt7/store/ <i>instance-name</i>	*.DB	Performance data file
13		*.IDX	Index files for performance data files
14		*.LCK	Lock files for performance data files
15		jpcsto.ini	Service startup initialization file of Remote Monitor Store
16		jpcsto.ini.model ^{#2}	Model file for the service startup initialization file of Remote Monitor Store
17		status.dat	Intermediate file for internal processing
18		*.DAT	Definition file for a data model
19		dump	Export folder
20		backup	Backup folder
21		partial	Partial backup folder

No.	Storage directory	File name	Description
22	/opt ^{#1} /jplpc/agt7/store/ <i>instance-name</i>	import	Import folder
23		log	Storage folder for log files

#1

If you run a logical host, replace `opt` with *environment-directory*. An environment directory is a directory on the shared disk that is specified when the logical host is created.

#2

Use these sample files when you want to restore the settings to their initial values from when the instance environment was configured.

#3

Created when the health check function is enabled.

To change an instance environment, re-execute the `jpcconf inst setup` command, and then update each instance environment setting. For details about updating the instance environment settings, see [3.6.2 Updating an instance environment](#).

You can change some settings by using PFM - Web Console to edit properties. For details about the information that can be changed by editing properties, see [E.2 List of properties of the Remote Monitor Collector service](#).

In an instance environment, the service IDs are as follows:

Service IDs in an instance environment

- For the Remote Monitor Collector service
`7Ainstance-number instance-name [host-name]`
- For the Remote Monitor Store service
`7Sinstance-number instance-name [host-name]`
- For the Group Agent service
`7Ainstance-number instance-name [All@host-name]`

In PFM - RM for Platform, the instance name specified in the `jpcconf inst setup` command is displayed.

If the host name of the PFM - RM host is `host1` and `inst1` is specified as the instance name, the service IDs will be as follows:

- For the Remote Monitor Collector service
`7A1inst1[host1]`
- For the Remote Monitor Store service
`7S1inst1[host1]`
- For the Group Agent service
`7A1inst1[All@host1]`

For details about the service IDs, see the naming rules provided in the appendix in the *JPI/Performance Management Planning and Configuration Guide*.

You cannot set up an instance environment by using PFM - Web Console's facility for distributing agent-specific properties.

(4) Setting the monitored host

Set information about the monitored host for the instance that was set up in [\(3\) Setting up an instance environment](#). You can set a maximum of 50 monitored hosts for a single instance. To set multiple monitored hosts, repeat this procedure. However, if the number of monitored hosts is large, the desired performance might not be achieved depending on the

system's performance and environment. In this case, reduce the number of monitored hosts. Carefully validate the performance before starting operation.

For PFM - RM 11-00 or later, you can specify logical hosts as monitored hosts. Note, however, that you can specify logical hosts only when monitoring whether processes or services are running. For other monitoring, we recommend that you specify physical hosts.

Important

If you specify a logical host as a monitored host for any purpose other than monitoring whether processes or services are running, correct values will not be stored for the first performance data when the machine is switched.

Using common account information for monitored hosts

If `Y` is set for `UseCommonAccount` in the setting items for the monitored host, common account information[#] (ssh) that was created beforehand for the monitored host is used.

#

In health check monitoring, the common account information cannot be used.

The following table lists the correspondence between the setting items for the monitored host and those for common account information.

Table 3–26: Correspondence between the setting items for the monitored host and those for common account information

Setting items for the monitored host	Setting items for common account information (ssh)	Description
User	User	User name
Private_Key_File	Private_Key_File	Private key file name

Note 1:

Common account information must be created on the PFM - RM host beforehand.

Use the `jpcconf acc setup` command to create common account information. For details about the `jpcconf acc setup` command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

Note 2:

The settings and precautions required for creating common account information (ssh) are the same as for the corresponding monitoring target setting items. See the corresponding monitoring target setting items in [Table 3-28](#).

Important

To use common account information, you need to unify the account information settings so that you can connect to multiple monitoring targets by using a single set of account information. For this reason, there is a risk of greater negative impact if common account information is leaked. To avoid such a risk, determine whether to use common account information after considering security measures and information management.

Notes about setting the monitored host

- Before you set a monitored host, make sure that the procedure described in [3.2.1\(5\) Environment settings required for collecting performance data \(for UNIX\)](#) has been completed and the environment has been set up.
- Even if an invalid value is specified when setting up the monitored host, the monitored host creation command terminates normally. However, if you start record collection with any invalid settings, performance data is not

collected. For details about troubleshooting when performance data is not collected, see [9.2.3 PFM - RM for Platform was started, but no performance data is being collected](#).

(a) Monitoring target setting items that must be specified depending on what is monitored

The monitoring target setting items that must be specified differ depending on what is monitored. The following table lists and describes these monitoring target setting items that must be specified for each monitoring target.

Table 3–27: Monitoring target setting items that must be specified for each monitoring target

Item name	What is monitored	
	UNIX environment	Health check monitoring
Target Host	Y	Y
UseCommonAccount	D	T
TargetType	Y	Y
User	Y	N
Private_Key_File	Y	N
Port	D	N

Legend:

Y: Specification is required.

D: Specification is required if the default value is being changed.

T: There is no need to change the default value.

N: Specification is not required.

(b) Monitoring target setting items and values

The table below lists and describes the setting items and values for a monitored host. Check this information before you start operations.

Use the `jpccconf target setup` command to set up a monitored host.

For details about how to execute the `jpccconf target setup` command, see [\(d\) Execution in the interactive mode](#) and [\(e\) Execution in the non-interactive mode](#).

For details about the `jpccconf target setup` command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

Table 3–28: Setting items and values for the monitored host in PFM - RM for Platform

No.	Item name ^{#1}	Description	Setting	Default
1	Target Host	Specifies the name of the monitored host ^{#2} . Specify a host name that can be resolved. ^{#3} The specified monitored host name is used during performance data collection ^{#4} and health checking. If JP1/IM is linked, this name is also used as the event host name.	From 1 to 32 bytes of alphanumeric characters and the hyphen (-) are permitted. The name cannot begin with a hyphen (-). The specified value must be unique within the instance. ^{#5}	No monitored host name is specified. ^{#6}
2	UseCommonAccount	Specifies whether to use common account information.	Specify one of the following values: <ul style="list-style-type: none">Y: Use	N

No.	Item name ^{#1}	Description	Setting	Default
2	UseCommonAccount	Specifies whether to use common account information.	<ul style="list-style-type: none"> N: Do not use 	N
3	TargetType	Specifies the method for connecting to the monitored host. If the monitored host is running UNIX, the value should be <code>ssh</code> . For health check monitoring, the value should be <code>icmp</code> .	<ul style="list-style-type: none"> Specify <code>ssh</code> if the monitored host is running UNIX. Specify <code>icmp</code> for health check monitoring. 	<code>ssh</code>
4	User ^{#7}	Specifies the user used to log on to the monitored host. PFM - RM for Platform uses this user to log on to the monitored host and collect performance data.	From 1 to 256 bytes of characters are permitted. The tab character is not permitted.	--
5	Private_Key_File	Specifies the name of the private key file ^{#8} that is used with the SSH public key method.	From 1 to 256 bytes of characters are permitted. The tab character is not permitted.	<code>/opt/jplpc/agt7/.ssh/agt7</code>
6	Port	Specifies the port number of the SSH server on the monitored host.	Specify a value in the range from 1 to 65,535.	22

Legend:

--: No default is set.

#1

When the `jpcconf target setup` command is executed in the non-interactive mode, this item name is used as a product-specific label in the definition file. For details about commands in the non-interactive mode, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

#2

For health check monitoring, you can also specify hosts and hardware equipment that support the ICMP protocol (can communicate through `ping` command).

#3

To collect performance data and perform health checking, the name must be resolvable at least by the PFM - RM host.
If the JP1/IM linkage facility is used, the name must be resolvable by the JP1/IM host.

#4

Health check monitoring does not collect performance data.

#5

All cannot be used because it is a reserved word for group agents.

#6

If the specification is omitted, the host name of the PFM - RM host is assumed.

#7

For the login shell for the user to be specified, specify `bash`, `bsh`, or `ksh`.
This also applies when `User` in common account information (`ssh`) is used.

#8

If a connection attempt using the specified private key fails, the private key set by the SSH server (`IdentityFile`) is used for connection.
This also applies when `Private_Key_File` in common account information (`ssh`) is used.

(c) Monitored host setting items that are not displayed

Monitored host setting items are usually displayed by executing a command, but some are not displayed depending on the contents of other setting items or for some other reason. The table below describes conditions that prevent monitored host setting items from being displayed. It also shows the input values that are used in such cases.

Table 3–29: Conditions that prevent monitored host setting items from being displayed, and input values that are used

Item name	Conditions that prevent monitored host setting items from being displayed, and input values that are used
User	<ul style="list-style-type: none"> These items are not displayed when Y is specified for UseCommonAccount. <p>Input value: The value in the corresponding common account information is used as the input value. For details about the corresponding common account information, see Table 3-26.</p> <ul style="list-style-type: none"> This item is not displayed when icmp is specified for TargetType.
Private_Key_File	
Port	This item is not displayed when icmp is specified for TargetType.

(d) Execution in the interactive mode

1. Execute the `jpcconf target setup` command.

In PFM - RM for Platform, we recommend that you specify the host name of the monitored host as the name of the monitoring target.

The following example sets the monitored host `targethost1` with instance name `inst1` as the monitoring target:

```
jpcconf target setup -key RMPlatform -inst inst1 -target targethost1
```

2. Set up the monitoring target for PFM - RM for Platform.

Enter setting items for the monitored host according to the instructions given by the command. For details about the setting items for the monitored host, see [Table 3-28](#). After you input each setting item, press the **Enter** key to set it. To use a displayed default value, simply press the **Enter** key.

The following is an example of the settings when the monitored host is running UNIX:

Conditions for the PFM - RM host to be set up

- SSH client program: `/usr/bin/ssh`
- Private key: `/opt/jplpc/agt7/.ssh/agt7`

Conditions for the monitored host to be set up

- Host name: `targethost1`
- User: `ssh-user`
- Port number of SSH: `22`

```
/opt/jplpc/tools>jpcconf target setup -key RMPlatform -inst inst1 -target
targethost1
Target Host          []                :targethost1<Enter>
UseCommonAccount     [N]              :<Enter>
TargetType           [ssh]             :<Enter>
User#1               :ssh-user<Enter>
Private_Key_File#1   [/opt/jplpc/agt7/.ssh/agt7]:<Enter>
Port                 [22#2]            :<Enter>
KAVE05361-I The monitoring target is now being added.
(servicekey#3=RMPlatform, inst=inst1, target=targethost1)
KAVE05362-I The monitoring target has been added.
(servicekey#3=RMPlatform, inst=inst1, target=targethost1)
```

#1

This item is not displayed when Y is specified for UseCommonAccount.

#2

If the port number used in SSH is not 22, change the value of `Port` to the port number used in SSH.

#3

If PFM - Manager's product name display function is disabled, `agt7` is displayed for `servicekey`.

The following is an example of the settings for health check monitoring:

Conditions for the monitored host to be set up

- Host name: `targethost2`

```
/opt/jplpc/tools>jpcconf target setup -key RMPlatform -inst inst1 -target
targethost2
Target Host                []                :targethost2<Enter>
UseCommonAccount           [N]             :<Enter>
TargetType                 [ssh]            :icmp<Enter>
KAVE05361-I The monitoring target is now being added.
(servicekey#=RMPlatform, inst=inst1, target=targethost2)
KAVE05362-I The monitoring target has been added.
(servicekey#=RMPlatform, inst=inst1, target=targethost2)
```

#

If PFM - Manager's product name display function is disabled, `agt7` is displayed for `servicekey`.

(e) Execution in the non-interactive mode

1. Execute the `jpcconf target setup` command to create a definition file template.

```
jpcconf target setup -key RMPlatform -noquery -template definition-file-
name
```

Sections and labels that correspond to the monitored host setting items are output to a definition file. Note that the value for the label of the `Target Definitions` section is left blank.

2. Edit the definition file template created in step 1.

Edit the template setting values as required for the monitored host.

For details about the product-specific labels to be specified in the definition file, see [Table 3-28](#).

Shown below is an example of the coding of a definition file when the monitored host is running UNIX. Specify values for the labels in the `Target Definitions` section as required for the monitored host.

```
[Common Definitions]
Definition File Version=0001

[Product Information]
Product ID=7

[Target Definitions]
Target Host=targethost1
UseCommonAccount=
TargetType=ssh
User#=user1
Private_Key_File#=/opt/jplpc/agt7/.ssh/agt7
Port=22
```

#

There is no need to specify a value for this item when Y is specified for UseCommonAccount.

Shown below is an example of the coding of a definition file for health check monitoring. Specify values for the labels in the Target Definitions section as required for the monitored host.

```
[Common Definitions]
Definition File Version=0001

[Product Information]
Product ID=7

[Target Definitions]
Target Host=targethost2
UseCommonAccount=
TargetType=icmp
User=
Private_Key_File=
Port=
```

3. Execute the jpcconf target setup command to set up the monitoring target for PFM - RM for Platform.

Shown below is an example of executing a command for setting up a monitoring target where inst1 is the instance name and targethost1 is the monitored host. For the -input option, specify the definition file edited in step 2.

```
jpcconf target setup -key RMPlatform -inst inst1 -target targethost1 -
input definition-file-name -noquery
```

Note:
If the definition file contains confidential information such as passwords, save the definition file in a secure location, and delete it after you have used it. If you want to transfer the definition file between hosts, we recommend that you use a secure file transfer protocol, such as Secure File Transfer Protocol (SFTP), which is FTP over an SSH tunnel.

When all of the settings have been completed, a monitoring target environment can be built. The following table shows the directory structure of the monitoring target environment.

Table 3–30: Directory structure of the monitoring target environment

No.	Storage directory	File name	Description
1	/opt#/jplpc/agt7/agent/instance-name/targets	monitoring-target-name.ini	Monitoring target settings file
2		monitoring-target-name.ini.model	Sample of a monitoring target settings file
3	/opt#/jplpc/agt7/agent/instance-name/targets/monitoring-target-name	--	Work directory for the monitoring target

Legend:
--: Not applicable

#

If you run a logical host, replace opt with environment-directory.

The following service IDs are added by the monitoring target settings:

Service IDs to be added

- Remote Agent service

```
7Ainstance-number instance-name [monitoring-target-name@host-name]
```

The instance name and monitoring target name will be the values specified in the `jpccnf target setup` command.

If you specify `host1` as the host name of the PFM - RM host, `inst1` as the instance name, and `targethost1` as the monitoring target name, then the service ID will be as follows:

```
7Ainst1[targethost1@host1]
```

For details about the service IDs, see the naming rules provided in the appendix in the *JPI/Performance Management Planning and Configuration Guide*.

If you want to change information about the monitoring target, re-execute the `jpccnf target setup` command and update the information. For details about updating a monitoring target, see [3.6.3 Updating a monitoring target](#).

You can change some settings by using PFM - Web Console to edit properties. For details about the information that can be changed by editing properties, see [E.3 List of properties of remote agents and group agents](#).

(5) Network settings Optional

You must specify network settings only if you need to change the network environment settings based on the network configuration specified where Performance Management is used.

There are two types of network environment settings, as described below. Change network settings as necessary.

- IP address setting

Set this information to use Performance Management in a network that is connected to multiple LANs. You set multiple IP addresses by defining the host names and IP addresses in the `jpchosts` file. Make sure that the specified `jpchosts` file is consistent throughout the entire Performance Management system.

For details about the IP address settings, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

- Port number setting

Set the port numbers used by Performance Management. To avoid confusion during operation, make sure that the specified port numbers and service names are consistent throughout the entire Performance Management system.

For details about the port number settings, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

(6) Changing the log file size Optional

The operation status of Performance Management is output to log files unique to Performance Management. This setting is required in order to change the size of these log files.

For the common message log, two files with a size of 2,048 kilobytes each are used by default. For details about changing the common message log, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

(7) Changing performance data storage locations Optional

These settings are required in order to change the following settings for the performance data that is managed by PFM - RM for Platform:

- Database storage location

By default, `/opt/jplpc/agt7/store/instance-name/` is set.

- Backup location

By default, `/opt/jplpc/agt7/store/instance-name/backup/` is set.

- Partial backup location

By default, `/opt/jplpc/agt7/store/instance-name/partial/` is set.

- Export location

By default, `/opt/jplpc/agt7/store/instance-name/dump/` is set.

- Import location

By default, `/opt/jplpc/agt7/store/instance-name/import/` is set.

Note

If you use a logical host for operation, replace `opt` with *environment-directory*.

For details about changing performance data storage locations, see [3.6.1 Changing performance data storage locations](#).

(8) Setting the connection-target PFM - Manager

You must specify on the PFM - RM host information about the PFM - Manager that manages PFM - RM for Platform. The `jpccconf mgrhost define` command is used to make this setting.

Notes about setting the connection-target PFM - Manager

- Only one PFM - Manager can be set as the connection destination even when multiple PFM - RMs are installed on the same host. A different PFM - Manager cannot be specified for each PFM - RM.
- If PFM - RM for Platform and PFM - Manager are installed on the same host, then the PFM - Manager on the local host is the connection-target PFM - Manager. In this case, you cannot change the connection-target PFM - Manager to any other PFM - Manager. To connect to PFM - Manager on a remote host, install PFM - RM for Platform on a different host than for PFM - Manager.

To set the connection-target PFM - Manager:

1. Stop the Performance Management programs and services.

If any Performance Management programs and services are running on the local host, stop all of them before starting the setup procedure. If Performance Management programs and services are running during execution of the `jpccconf mgrhost define` command, a message is displayed that asks you to terminate them.

For details about how to stop services, see the chapter that describes starting and stopping Performance Management in the *JP1/Performance Management User's Guide*.

2. Execute the `jpccconf mgrhost define` command with the host name of the connection-target PFM - Manager specified.

The following shows an example of command execution when the connection-target PFM - Manager is located on the `host01` host:

```
jpccconf mgrhost define -host host01
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf mgrhost define` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

(9) Action log output settings Optional

These settings are required in order to output action logs at the following times:

- When a PFM service starts
- When a PFM service stops
- When the PFM - Manager connection status is changed

An action log contains log information about exceeded threshold values caused by factors such as system overloads; its output is linked with the alarm function. For details about the action log output settings, see [I. Outputting Action Log Data](#).

3.2.5 SSH (for UNIX) connection setting method

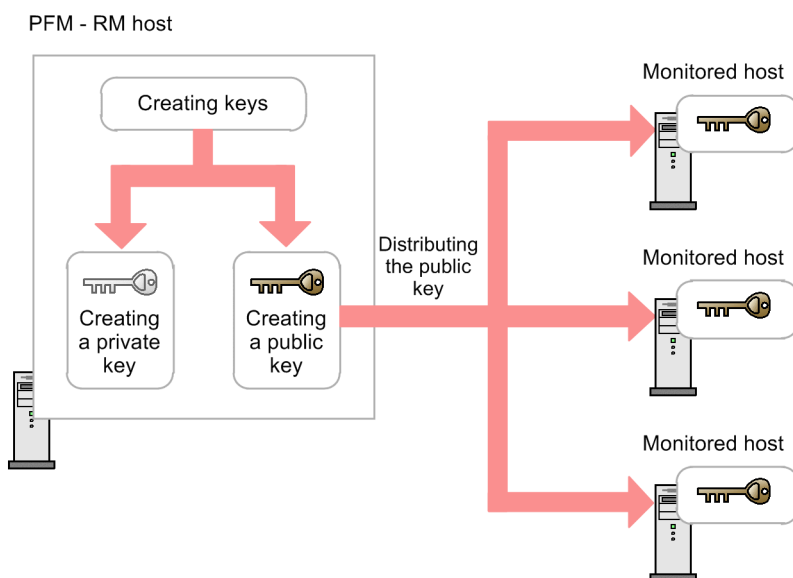

This subsection describes how to set SSH connection. For SSH authentication, the public key authentication method is used.

To connect SSH, you need the following settings:

- Enabling the SSH server's public key authentication
Specify this setting at the monitored hosts.
- Creating keys
Specify this setting at the PFM - RM host.
- Placing the private key on the PFM - RM host
Specify this setting at the PFM - RM host.
- Placing the public key on the monitored hosts
Specify this setting at the monitored hosts.

The following figure shows the concept of public key authentication.

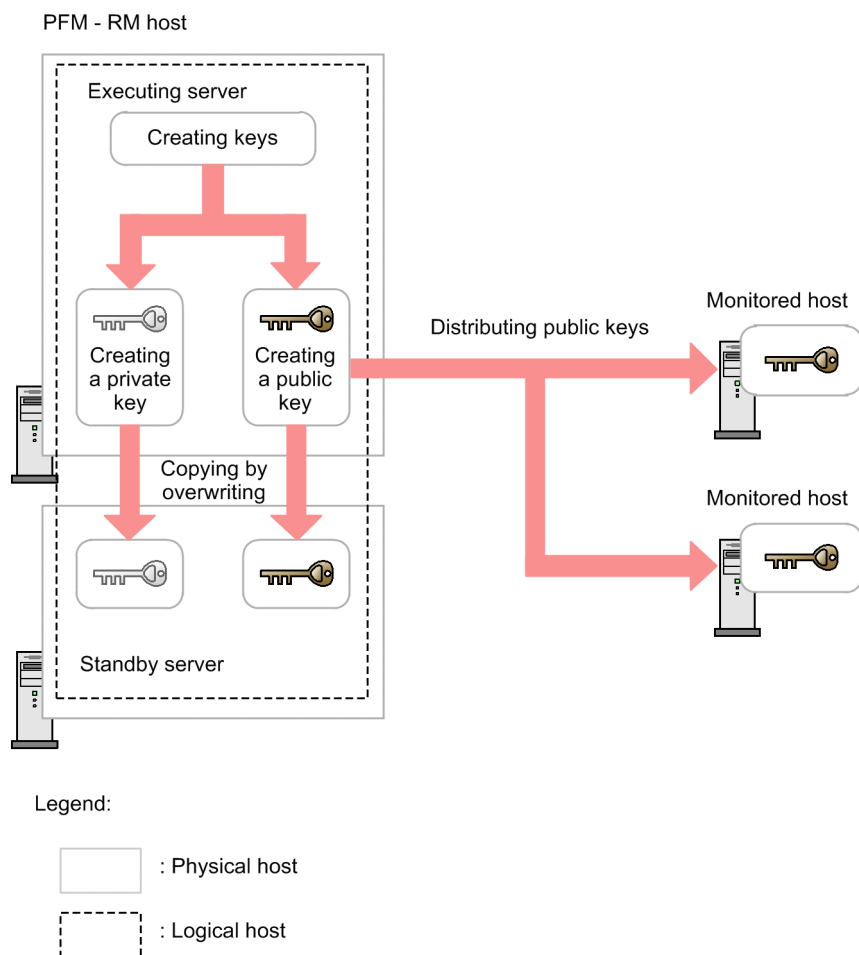

Figure 3–16: Concept of public key authentication

There are two ways to perform public key authentication in a cluster system. One is by using the same key for both executing and standby nodes, and the other is by using different keys.

To use the same key for both executing and standby nodes, copy the standby node's key file to the executing node's key file by overwriting. The following figure shows the concept of public key authentication using the same key.

Figure 3–17: Concept of public key authentication (using the same key for both executing and standby nodes)

To use different keys for the executing and standby nodes, you must register the key files for both the executing node and the standby node into the monitored hosts. The following figure shows the concept of public key authentication using different keys.

Figure 3–18: Concept of public key authentication (using different keys for executing and standby nodes)

(1) Enabling the SSH server's public key authentication

To enable public key authentication:

1. Log on to the monitored host as a superuser.
2. Open `/etc/ssh/sshd_config#`.
3. Set `PubkeyAuthentication` to `yes`.
4. Save and close `/etc/ssh/sshd_config#`.
5. Execute the following command to restart the `sshd` service:

- For Linux 7 or SUSE Linux 12

```
[root@TargetHost.ssh]$ systemctl restart sshd.service
```

- For other OS

```
[root@TargetHost.ssh]$ /etc/rc.d/init.d/sshd restart
```

Note

To log on as a superuser to collect information, open `/etc/ssh/sshd_config`[#] and change `PermitRootLogin` to `yes`. After that, restart the `sshd` service.

#

This will be `/opt/ssh/etc/sshd_config` when using HP-UX.

(2) Creating keys

Keys are created automatically. Although you can create keys manually, we recommend that you use the keys that are created automatically unless otherwise necessary.

(a) Creating keys automatically

When you install PFM - RM for Platform, both private and public keys are created automatically in `/opt/jplpc/agt7/.ssh/`.

The following table lists and describes the storage directory for the private and public keys, the file names, and the settings.

Table 3–31: Storage directory for the private and public keys, the file names, and settings

No.	Storage directory and file name		Attribute	Owner	Description
1	/opt/jplpc/agt7/.ssh/	--	700	root:root	Hidden directory for storing private and public keys
2		agt7	600		Private key file
3		agt7.pub	644		Public key file

Legend:

--: Not applicable

Important

When you use an automatically created key, do not delete the created key file. If you delete it, the key information will not match the monitored host when the key file is automatically re-created due to an overwrite installation or version upgrade. Consequently, you will no longer be able to connect to the monitored host. If you cannot connect the monitored host following an overwrite installation or version upgrade because the key file has been deleted, perform the procedure described in [\(3\) Placing the public key on the monitored hosts](#) and place the public key on all monitored hosts again.

(b) Creating keys manually

This subsection describes how to create keys manually.

You can create keys by logging on to the PFM - RM host as a superuser and then executing the `ssh-keygen` command. The only difference between RSA and DSA encryption is the encryption algorithms; their operation methods are the same.

To create RSA keys:

1. Log on to the PFM - RM host as a superuser.
2. Execute the `ssh-keygen -t rsa` command.

This command creates an RSA key.

To create a DSA key, specify the `-s dsa` option instead of the `-t rsa` option.

3. Determine the destination and name of the private key.

By default, `~/.ssh/id_rsa` (RSA) is set.

4. Press the **Enter** key twice.

When you are asked to enter a pass phrase for the private key, press the **Enter** key without entering anything. When re-entry is prompted, press the **Enter** key again without entering anything.

The following shows an example of `ssh-keygen -t rsa` command execution:

```
[root@RMHost]$ ssh-keygen -t rsa
Generating public/private rsa key pair.
Enter file in which to save the key (/root/.ssh/id_rsa): <Enter>
Enter passphrase (empty for no passphrase): <Enter>
Enter same passphrase again: <Enter>
Your identification has been saved in /root/.ssh/id_rsa.
Your public key has been saved in /root/.ssh/id_rsa.pub.
The key fingerprint is:
ax:xx:xx:xx:xx:bx:xx:xc:xx:xx:xx:xd:xd:xa:ed:xx root@RMHost
```

Notes about creating keys

- Securely manage information about private keys.
- Creation of keys (a pair of public and private keys) should not introduce any problem in any environment or tool because it does not depend on environments or tools. However, after creating keys, you must place the private and public keys appropriately.

(3) Placing the public key on the monitored hosts

Place the created public key on the monitored hosts. When there are multiple monitored hosts, be sure to perform this procedure on all of them.

To place the public key on a monitored host:

1. Log on to the monitored host by using the value that was specified in `User` during monitoring target setup.
To use common account information, specify the value that is specified in `User` in common account information (ssh).
2. Execute the `cd` command to change the current directory to the `.ssh` directory under the home directory.
If the `.ssh` directory does not exist under the home directory, create it. For the `.ssh` directory attribute, specify 700 or 755. For the owner and group, specify the same as those specified for the user who was specified during the setup of the monitored host. If the attribute, owner, or group setting of the home directory or the `.ssh` directory is invalid, SSH connection might fail.
3. Execute the `scp` command.
The public key file that has already been created is received.
4. Execute the `cat` command.

The contents of the public key file are redirected to the authentication key file. Also, the contents of the received public key file are added to the authentication key file.

The name of the authentication key file is set by `AuthorizedKeysFile` of `/etc/ssh/sshd_config`. For HP-UX, it is `/opt/ssh/etc/sshd_config`.

By default, `~/.ssh/authorized_keys` is set.

5. Execute the `rm` command to delete the received public key file.

6. Execute the `chmod` command to change the attribute of the authentication key file to 600.

An example of performing steps 2 through 6 follows:

```
[ClientUser@TargetHost ]$ cd .ssh
[ClientUser@TargetHost .ssh]$ scp root@RMHost:/opt/jplpc/agt7/.ssh/
agt7.pub .
root@RMHost's password: password
agt7.pub                               100% 233      0.2KB/s   00:00
[ClientUser@TargetHost .ssh]$ cat agt7.pub >> authorized_keys
[ClientUser@TargetHost .ssh]$ rm agt7.pub
[ClientUser@TargetHost .ssh]$ chmod 600 authorized_keys
```

You can also execute the `ssh-copy-id` command on the PFM - RM host to place the public key on the monitored hosts. When you use the `ssh-copy-id` command, there is no need to change the specification of the `.ssh` directory in which to place the public key, or the name and attribute of the public key.

To use the `ssh-copy-id` command to place the public key:

1. Log on to the PFM - RM host as a superuser.

2. Execute the `ssh-copy-id` command.

The public key is copied.

For details about the `ssh-copy-id` command, see the OpenSSH documentation.

An example of performing steps 1 and 2 follows:

```
[root@RMHost ]$ /usr/bin/ssh-copy-id -i /opt/jplpc/agt7/.ssh/agt7.pub
ClientUser@TargetHost
29
The authenticity of host 'TargetHost (xxx.xxx.xxx.xxx)' can't be
established.
RSA key fingerprint is xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'TargetHost,xxx.xxx.xxx.xxx' (RSA) to the list
of known hosts.
ClientUser@TargetHost's password: password
Now try logging into the machine, with "ssh 'ClientUser@TargetHost'", and
check in:

    .ssh/authorized_keys

to make sure we haven't added extra keys that you weren't expecting.
```

(4) Checking the connection and registering a fingerprint

To check whether the PFM - RM host and a monitored host can connect to each other:

1. Log on to the PFM - RM host as a superuser.
2. Using the created private key, execute the `ssh` client command on the monitored host.
The connection process begins.
3. During the initial connection, register a fingerprint.
Register the fingerprint of the public key of the monitored host. Here, enter `yes`. When you enter `yes`, the monitored host's command prompt appears.
4. From the monitored host's command prompt, execute the `exit` command to log out from the monitored host.
5. From the PFM - RM host, execute the `ssh` client command on the monitored host to reconnect to it.
If the monitored host's prompt appears in subsequent connections without you having to enter any information, setup of the connection between the PFM - RM host and the monitored host is completed. From the monitored host's command prompt, execute the `exit` command to log out from the monitored host.
If an error occurs or an entry is requested, check if the procedure was executed correctly.

The following shows an example of the settings for checking the connection:

```
[root@RMHost]$ /usr/bin/ssh -i /opt/jplpc/agt7/.ssh/agt7 -p 22
ClientUser@TargetHost
The authenticity of host 'TargetHost (xxx.xxx.xxx.xxx)' can't be
established.
RSA key fingerprint is xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx:xx.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'TargetHost,xxx.xxx.xxx.xxx' (RSA) to the list
of known hosts.
Last login: Mon Mar 23 17:17:52 2009 from xxx.xxx.xxx.xxx
[ClientUser@TargetHost ~]$ exit
logout

Connection to TargetHost closed.
[root@RMHost]$ /usr/bin/ssh -i /opt/jplpc/agt7/.ssh/agt7 -p 22
ClientUser@TargetHost
Last login: Mon Mar 23 17:18:00 2009 from xxx.xxx.xxx.xxx
[ClientUser@TargetHost ~]$ exit
logout

Connection to TargetHost closed.
[root@RMHost]$
```

Notes:

- PFM - RM for Platform assumes that fingerprint authentication has already been completed. Because you can register a fingerprint during the initial SSH client connection, we recommend that you complete the procedure described here at that point.
- Confirm that a response is returned in less than 10 seconds when you execute a command such as `uname` on the monitored host from the PFM - RM host.

For details about PFM - Manager startup, see the chapter that describes startup and termination of Performance Management in the *JPI/Performance Management User's Guide*.

3.2.6 Notes about installation and setup of the UNIX edition

(1) Notes about environment variables

Performance Management uses the `JPC_HOSTNAME` environment variable. Do not set a user-specific `JPC_HOSTNAME` environment variable. If such an environment variable is set, Performance Management will not function correctly.

(2) Notes about installing multiple Performance Management programs on the same host (for UNIX)

The notes about installing multiple Performance Management programs on the same host are the same as for the Windows environment.

See [3.1.7\(3\) Notes about installing multiple Performance Management programs on the same host \(for Windows\)](#).

(3) Notes about upgrading (for UNIX)

For notes about upgrading the Performance Management programs, see the section that presents notes about upgrading in the chapter describing installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

For notes about upgrading PFM - RM for Platform, see [G. Migration Procedure and Notes on Migration](#).

For details about upgrading, see the relevant Appendix in the *JPI/Performance Management Planning and Configuration Guide*.

(4) Notes about installing PFM - RM for Platform in a UNIX environment

This subsection provides notes about installing PFM - RM for Platform in a UNIX environment.

- If you install PFM - RM for Platform in an environment where no Performance Management program has been installed, make sure that there are no folders or files in the installation folder.
- If `Install failed` is displayed on the status bar during installation and the installation fails, collect the `/etc/.hitachi/.hitachi.log` log file. This log file will be overwritten during the next installation process. Make a backup of this file, as required.
- If you install Performance Management programs by adding a link to the installation directory, some files and directories might remain in the linked directory even if you delete all Performance Management programs. You must delete these files and directories manually. Note that during installation, if a linked directory contains files and directories with the same names as source files and directories, those files and directories will be overwritten.
- If the `/opt/jplpc/setup` directory contains the setup file of PFM - RM for Platform, additional setup of a new PFM - RM for Platform will be executed.
- To run PFM - RM for Platform as services, use an account with superuser permissions.
- Before you install a Performance Management program, check to see if any of the security-related programs described below are installed. If such a program is installed, take appropriate action according to the information provided below.
 - Security monitoring program

Either terminate the security monitoring program or change its settings so that installation of the Performance Management program will not be affected.

- Virus detection program

We recommend that you terminate any virus detection program before you install the Performance Management programs.

If a virus detection program is running during installation of a Performance Management program, it might slow down the installation process, the installation might fail, or the program might not install correctly.

- Process monitoring program

Either terminate the process monitoring program or change its settings so that it does not monitor Performance Management services and processes as well as services and processes of common components.

Installation of a Performance Management program might fail if these services and processes are started or stopped by the process monitoring program during the installation process.

3.3 Uninstallation and unsetup of the Windows edition

This section describes how to uninstall PFM - RM for Platform and cancel its setup in a Windows environment.

3.3.1 Issues to consider before uninstalling and canceling the setup for the Windows edition

This subsection provides notes about uninstalling PFM - RM for Platform and canceling its setup.

(1) Notes about OS user permissions required for uninstallation

When you uninstall PFM - RM for Platform, make sure that you use an account that has Administrator permissions.

(2) Notes about network

Uninstalling a Performance Management program does not delete the port numbers defined in the `services` file.

(3) Notes about programs

- If you uninstall PFM - RM for Platform while Performance Management programs and services or other programs that reference Performance Management files (such as Windows Event Viewer) are running, some files and folders might remain in the system. In such a case, you must manually delete all files and folders under the installation folder.
- If you uninstall PFM - RM for Platform in the states described below, files or folders might remain. In this case, you must manually delete all files and folders from *installation-folder\agt7*. If you are using PFM - RM for Platform in a logical host environment, delete files and folders from *environment-folder\jplpc\agt7* in the same way.
 - A Performance Management program or service is running.
 - Another program (such as Windows Event Viewer) that references a Performance Management file is running.
 - A file or folder under *installation-folder\agt7* is being referenced.
- If you attempt to uninstall PFM - RM for Platform while Performance Management programs and services or other programs that reference Performance Management files (such as Windows Event Viewer) are running, a message prompting system restart might be displayed. If this occurs, restart the system to complete the uninstallation procedure.
- If PFM - Base and PFM - RM for Platform are both installed on the same host, PFM - Base cannot be uninstalled unless you uninstall PFM - RM for Platform. In such a case, uninstall PFM - RM for Platform, and then uninstall PFM - Base. Similarly, if PFM - Manager and PFM - RM for Platform are installed on the same host, PFM - Manager cannot be uninstalled unless you uninstall PFM - RM for Platform. In this case, uninstall PFM - RM for Platform, and then uninstall PFM - Manager.

(4) Notes about services

Uninstalling PFM - RM for Platform might not delete the service information that is displayed by the `jpctool service list` command. In such a case, use the `jpctool service delete` command at the host where PFM - Manager is installed to delete the service information. To have the deletion of service information apply to the PFM - Web Console host, you must execute the `jpctool service sync` command to synchronize the agent information between the PFM - Manager host and the PFM - Web Console host.

(5) Other notes

To uninstall Performance Management programs from a host on which PFM - Web Console is installed, close all browser windows before you start the uninstallation.

3.3.2 Procedure for canceling the setup for the Windows edition

This subsection describes how to cancel the setup of PFM - RM for Platform.

(1) Canceling the setup for a monitoring target

To cancel the setup for a monitoring target, first check the name of the monitoring target, and then use the PFM - RM host to delete the monitoring target.

To check the name of a monitoring target, use the `jpccconf target list` command. To delete a configured monitoring target, use the `jpccconf target unsetup` command.

Note

There is no need to stop PFM - RM for Platform services while you are deleting a monitoring target.

To delete a monitoring target:

1. Check the name of the monitoring target.

Execute the `jpccconf target list` command with the service key that indicates PFM - RM for Platform and the instance name specified:

```
jpccconf target list -key RMPlatform -inst inst1
```

The names of all monitoring targets are displayed:

```
Targets:
targethost1
targethost2
Groups:
All
```

2. Delete the desired monitoring target.

Execute the `jpccconf target unsetup` command with the service key that indicates PFM - RM for Platform, the instance name, and the name of the monitoring target specified:

```
jpccconf target unsetup -key RMPlatform -inst inst1 -target targethost1
```

When the `jpccconf target unsetup` command in this example terminates normally, `targethost1` will no longer be a monitoring target.

Important

If you delete the monitoring targets by executing the `jpccconf target unsetup` command, the service information is automatically deleted from PFM - Manager; therefore, there is no need to execute

the `jpctool service delete` command. The service information is deleted from PFM - Manager at the following times:

- If you execute the `jpccconf target unsetup` command while both PFM - Manager and the PFM - RM service to be deleted are running, PFM - RM requests PFM - Manager to delete the service information, and PFM - Manager deletes the service information.
- If you execute the `jpccconf target unsetup` command while both PFM - Manager and the PFM - RM service to be deleted are stopped, PFM - Manager deletes the service information when the PFM - RM service starts and connects to PFM - Manager.

To apply the deletion of the monitoring target to the PFM - Web Console host, you must execute the `jpctool service sync` command to synchronize the agent information between the PFM - Manager host and the PFM - Web Console host.

Canceling the setup for a monitoring target does not delete the folders and files listed below. You must delete these folders and files manually.

- `installation-folder#\agt7\agent\instance-name\targets\monitoring-target-name`
- `installation-folder#\agt7\agent\instance-name\log\target_monitoring-target-name_nn`

#

If you use a logical host for operation, replace *installation-folder* with *environment-folder\jp1pc*.

(2) Canceling an instance environment setup

To cancel the setup for an instance environment, first check the name of the instance, and then delete the instance environment. Execute deletion of an instance environment at the PFM - RM host. To check the name of an instance, use the `jpccconf inst list` command. To delete a configured instance environment, use the `jpccconf inst unsetup` command.

To delete an instance environment:

1. Check the name of the instance.

Execute the `jpccconf inst list` command with the service key that indicates PFM - RM for Platform specified:

```
jpccconf inst list -key RMPlatform
```

For example, if the set instance name is `inst1`, the command displays `inst1`.

2. If any services of PFM - RM for Platform are running in the instance environment, stop all of them.

For details about how to stop services, see the chapter that describes starting and stopping Performance Management in the *JP1/Performance Management User's Guide*.

3. Delete the instance environment.

Execute the `jpccconf inst unsetup` command with the service key that indicates PFM - RM for Platform and the instance name specified.

For example, if the set instance name is `inst1`, specify the command as follows:

```
jpccconf inst unsetup -key RMPlatform -inst inst1
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf inst unsetup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

When the `jpccconf inst unsetup` command terminates normally, the folders configured as the instance environment, the service ID, and the Windows services are deleted.

Important

Canceling the setup of an instance environment might not delete the service information that is displayed by the `jpctool service list` command. In such a case, use the `jpctool service delete` command at the host where PFM - Manager is installed to delete the service information.

To apply the deletion of the instance environment to the PFM - Web Console host, you must execute the `jpctool service sync` command to synchronize the agent information between the PFM - Manager host and the PFM - Web Console host.

- Instance name: `inst1`
- Host name: `lhost1`
- Service ID of the Remote Monitor Collector service: `7A1inst1[lhost1]`
- Service ID of the Remote Monitor Store service: `7S1inst1[lhost1]`
- Service ID of the Group Agent service: `7S1inst1[All@lhost1]`

```
jpctool service delete -id 7?1inst1[lhost1] -host lhost1
```

```
jpctool service delete -id 7?1inst1[*@lhost1] -host lhost1
```

For details about the commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

3.3.3 Procedure for uninstalling the Windows edition

To uninstall PFM - RM for Platform:

1. At the host where PFM - RM for Platform is to be uninstalled, log on as a user with Administrator permissions.

2. At the local host, stop the Performance Management programs and services.

Display the service information to make sure that no services are running. If any Performance Management programs and services are running on the local host, stop all the active programs and services. You must stop all services on both physical and logical hosts.

For details about how to display service information and how to stop services, see the chapter that describes startup and termination of Performance Management in the *JPI/Performance Management User's Guide*.

3. Select the Performance Management program to be uninstalled.

From the Windows **Control Panel**, choose **Programs and Features**, and then select the Performance Management program to be uninstalled.

4. Select **Remove**, and then click the **OK** button.

The selected program is uninstalled.

Important

- If the user account control functionality (UAC) is enabled in the operating system, the User Account Control dialog box might be displayed during uninstallation. If it is displayed, click the **Continue** button to continue uninstallation, or click the **Cancel** button to cancel uninstallation.
- If you changed the WMI connection settings in *3.1.5 WMI connection setting method (when both the PFM - RM host and the monitored host are running Windows)* but the change is no longer necessary, return the settings to their original values. If you specified a private key and a public key to be used for setting up SSH public key authentication in *3.1.6 SSH connection setting method for Windows (when the PFM - RM host is running Windows and the monitored host is running UNIX)*, delete these keys as necessary. Furthermore, if PuTTY and ActivePerl are not needed, uninstall them.

3.4 Uninstallation and unsetup of the UNIX edition

This section describes how to uninstall PFM - RM for Platform and cancel its setup in a UNIX environment.

3.4.1 Issues to consider before uninstalling and canceling the setup for the UNIX edition

This subsection provides notes about uninstalling PFM - RM for Platform and canceling its setup.

(1) Notes about OS user permissions required for uninstallation

When you uninstall PFM - RM for Platform, make sure that you use an account that has the superuser permissions.

(2) Notes about network

Uninstalling a Performance Management program does not delete the port numbers defined in the `services` file.

(3) Notes about programs

- If you uninstall PFM - RM for Platform while Performance Management programs and services or other programs that reference Performance Management files are running, some files and directories might remain in the system. In such a case, you must manually delete all files and directories under the installation directory.
- If PFM - Base and PFM - RM for Platform are both installed on the same host, PFM - Base cannot be uninstalled unless you uninstall PFM - RM for Platform. In such a case, uninstall PFM - RM for Platform, and then uninstall PFM - Base. Similarly, if PFM - Manager and PFM - RM for Platform are installed on the same host, PFM - Manager cannot be uninstalled unless you uninstall PFM - RM for Platform. In this case, uninstall PFM - RM for Platform, and then uninstall PFM - Manager.

(4) Notes about services

- When you uninstall PFM - Manager, make sure that all Performance Management programs and services are stopped throughout the entire Performance Management system.
- Uninstalling PFM - RM for Platform might not delete the service information that is displayed by the `jpctool service list` command. In such a case, use the `jpctool service delete` command at the host where PFM - Manager is installed to delete the service information. To apply the deletion of service information to the PFM - Web Console host, you must execute the `jpctool service sync` command to synchronize the agent information between the PFM - Manager host and the PFM - Web Console host.

3.4.2 Procedure for canceling the setup for the UNIX edition

This subsection describes how to cancel the setup of PFM - RM for Platform.

(1) Canceling the setup for a monitoring target

To cancel the setup for a monitoring target, first check the name of the monitoring target, and then use the PFM - RM host to delete the monitoring target.

To check the name of a monitoring target, use the `jpccconf target list` command. To delete a configured monitoring target, use the `jpccconf target unsetup` command.

Note

There is no need to stop PFM - RM for Platform services while you are deleting a monitoring target.

To delete a monitoring target:

1. Check the name of the monitoring target.

Execute the `jpccconf target list` command with the service key that indicates PFM - RM for Platform and the instance name specified.

```
jpccconf target list -key RMPlatform -inst inst1
```

The names of all monitoring targets are displayed:

```
Targets:
targethost1
targethost2
Groups:
All
```

2. Delete the desired monitoring target.

Execute the `jpccconf target unsetup` command with the service key that indicates PFM - RM for Platform, the instance name, and the name of the monitoring target specified:

```
jpccconf target unsetup -key RMPlatform -inst inst1 -target targethost1
```

When the `jpccconf target unsetup` command in this example terminates normally, `targethost1` will no longer be a monitoring target.

Important

If you delete the monitoring targets by executing the `jpccconf target unsetup` command, the service information is automatically deleted from PFM - Manager; therefore, there is no need to execute the `jpctool service delete` command. The service information is deleted from PFM - Manager at the following times:

- If you execute the `jpccconf target unsetup` command while both PFM - Manager and the PFM - RM service to be deleted are running, PFM - RM requests PFM - Manager to delete the service information, and PFM - Manager deletes the service information.
- If you execute the `jpccconf target unsetup` command while both PFM - Manager and the PFM - RM service to be deleted are stopped, PFM - Manager deletes the service information when the PFM - RM service starts and connects to PFM - Manager.

To apply the deletion of the monitoring target to the PFM - Web Console host, you must execute the `jpctool service sync` command to synchronize the agent information between the PFM - Manager host and the PFM - Web Console host.

For details about the commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

Canceling the setup for a monitoring target does not delete the directories and files listed below. You must delete these directories and files manually.

- `/opt#/jplpc/agt7/agent/instance-name/targets/monitoring-target-name`
- `/opt#/jplpc/agt7/agent/instance-name/log/target_monitoring-target-name_nn`

#

If you use a logical host for operation, replace `opt` with *environment-directory*.

(2) Canceling an instance environment setup

To cancel the setup for an instance environment, first check the name of the instance, and then delete the instance environment. Execute deletion of an instance environment at the PFM - RM host. To check the name of an instance, use the `jpccconf inst list` command. To delete a configured instance environment, use the `jpccconf inst unsetup` command.

To delete an instance environment:

1. Check the name of the instance.

Execute the `jpccconf inst list` command with the service key that indicates PFM - RM for Platform specified.

```
jpccconf inst list -key RMPlatform
```

For example, if the set instance name is `inst1`, the command displays `inst1`.

2. If any services of PFM - RM for Platform are running in the instance environment, stop all of them.

For details about how to stop services, see the chapter that describes starting and stopping Performance Management in the *JP1/Performance Management User's Guide*.

3. Delete the instance environment.

Execute the `jpccconf inst unsetup` command with the service key that indicates PFM - RM for Platform and the instance name specified.

For example, if the set instance name is `inst1`, specify the command as follows:

```
jpccconf inst unsetup -key RMPlatform -inst inst1
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf inst unsetup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

When the `jpccconf inst unsetup` command terminates normally, the directories configured as the instance environment and the service ID are deleted.

Important

Canceling the setup of an instance environment might not delete the service information that is displayed by the `jpctool service list` command. In this case, use the `jpctool service delete` command on the host where PFM - Manager is installed to delete the service information.

To apply the deletion of the instance environment to the PFM - Web Console host, you must execute the `jpctool service sync` command to synchronize the agent information between the PFM - Manager host and the PFM - Web Console host.

In such a case, use the `jpctool service delete` command at the host where PFM - Manager is installed to delete the service information. After the command executes, restart the PFM - Manager service. The following shows a specification example:

- Instance name: `inst1`
- Host name: `lhost1`
- Service ID of the Remote Monitor Collector service: `7A1inst1[lhost1]`
- Service ID of the Remote Monitor Store service: `7S1inst1[lhost1]`
- Service ID of the Group Agent service: `7S1inst1[All@lhost1]`

```
jpctool service delete -id 7?1inst1[lhost1] -host lhost1
```

```
jpctool service delete -id 7?1inst1[*@lhost1] -host lhost1
```

For details about the commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

3.4.3 Procedure for uninstalling the UNIX edition

To uninstall PFM - RM for Platform:

1. At the host where a Performance Management program is to be uninstalled, log on as superuser. Alternatively, use the `su` command to change the user to a superuser.

2. At the local host, stop the Performance Management programs and services.

Display the service information to make sure that no services are running. If any Performance Management programs and services are running on the local host, stop all the active programs and services. You must stop all services on both physical and logical hosts.

For details about how to display service information and how to stop services, see the chapter that describes startup and termination of Performance Management in the *JPI/Performance Management User's Guide*.

3. Execute the following command to start the Hitachi Program Product Installer:

```
/etc/hitachi_x64setup
```

The Hitachi Program Product Installer starts and the initial window is displayed.

4. In the initial window, enter `D`.

A list of programs that can be uninstalled is displayed.

5. Select the Performance Management program that you want to uninstall, and then enter `D`.

The selected program is uninstalled. To select another program, move the cursor to the desired program, and then press the space key to select it.

6. When uninstallation is completed successfully, enter `Q`.

The initial window of the Hitachi Program Product Installer is displayed again.

Important

If you specified a private key and a public key to be used for setting up SSH public key authentication in [3.2.5 SSH \(for UNIX\) connection setting method](#), delete these keys as necessary.

3.5 Changing the PFM - RM for Platform system configuration

When a change occurs, such as the monitoring target system's network configuration and host names, you must change the system configuration for PFM - RM for Platform.

When you change the system configuration for PFM - RM for Platform, you must also change the settings for PFM - Manager and PFM - Web Console. For details about how to change the system configuration for Performance Management, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

3.6 Changing the PFM - RM for Platform operation method

It might be necessary to change the operation method for PFM - RM for Platform for a reason such as a change made to the method for handling the collected operation monitoring data. This section describes how to change the operation method for PFM - RM for Platform.

For details about how to change the operation method for the entire Performance Management system, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

3.6.1 Changing performance data storage locations

The performance data collected by PFM - RM for Platform is managed in the Store database of the Remote Monitor Store service of PFM - RM for Platform. This subsection describes how to change performance data storage locations.

You use the `jpccconf db define` command to change the storage directories listed below for performance data managed in the Store database. For details about the `jpccconf db define` command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

- Storage directory
- Backup directory
- Export directory
- Partial backup directory
- Import directory

(1) In Windows

The following table lists and describes the option names set by the `jpccconf db define` command and their permitted values.

Table 3–32: Items set by the `jpccconf db define` command (for Windows)

No.	Option name	Description	Permitted value (Store version 2.0)	Default
1	bd	Sets the performance data backup folder ^{#1}	Path name of 1 to 211 bytes	<i>installation-folder</i> ^{#2} \agt7\store \instance-name\backup
2	bs	Sets the maximum generation number when performance data is backed up	From 1 to 9	5
3	id	Sets the performance data import folder ^{#1}	Path name of 1 to 222 bytes	<i>installation-folder</i> ^{#2} \agt7\store \instance-name\import
4	pbd	Sets the performance data partial backup folder ^{#1}	Path name of 1 to 214 bytes	<i>installation-folder</i> ^{#2} \agt7\store \instance-name\partial
5	dd	Sets the performance data export folder ^{#1}	Path name of 1 to 127 bytes	<i>installation-folder</i> ^{#2} \agt7\store \instance-name\dump
6	sd	Sets the performance data creation folder ^{#1}	Path name of 1 to 214 bytes	<i>installation-folder</i> ^{#2} \agt7\store \instance-name

#1

Specify either the folder name relative to the default Store database storage folder (*installation-folder\agt7\store\instance-name*) or the absolute path.

#2

For the default values for logical host operation, replace *installation-folder* with *environment-folder\jplpc*.

(2) In UNIX

The following table lists and describes the option names set by the `jpccconf db define` command and their permitted values.

Table 3–33: Items set by the `jpccconf db define` command (for UNIX)

No.	Option name	Description	Permitted value (Store version 2.0)	Default
1	bd	Sets the performance data backup directory ^{#1}	Path name of 1 to 211 bytes	/opt ^{#2} /jplpc/agt7/store/ <i>instance-name</i> /backup
2	bs	Sets the maximum generation number when performance data is backed up	From 1 to 9	5
3	id	Sets the performance data import directory ^{#1}	Path name of 1 to 222 bytes	/opt ^{#2} /jplpc/agt7/store/ <i>instance-name</i> /import
4	pbd	Sets the performance data partial backup directory ^{#1}	Path name of 1 to 214 bytes	/opt ^{#2} /jplpc/agt7/store/ <i>instance-name</i> /partial
5	dd	Sets the performance data export directory ^{#1}	Path name of 1 to 127 bytes	/opt ^{#2} /jplpc/agt7/store/ <i>instance-name</i> /dump
6	sd	Sets the performance data creation directory ^{#1}	Path name of 1 to 214 bytes	/opt ^{#2} /jplpc/agt7/store/ <i>instance-name</i>

#1

Specify either the directory name relative to the default Store database storage directory (`/opt/jplpc/agt7/store/instance-name`) or the absolute path.

#2

For the default values for logical host operation, replace `opt` with *environment-directory*.

3.6.2 Updating an instance environment

This subsection describes how to change an instance environment of PFM - RM for Platform while the Performance Management system is running.

(1) In Windows

To update an instance environment, check the instance name, and then update individual instance environment settings. Use the PFM - RM host to set individual instance environment settings.

Use the following table to check the information to be updated beforehand.

Table 3–34: Instance environment settings for PFM - RM for Platform (for Windows)

No.	Item name	Description	Setting	Default
1	UseCommonAccount [#]	Specifies whether to use common account information.	Specify one of the following values: <ul style="list-style-type: none"> Y: Use N: Do not use 	Previous setting
2	Interval	Specifies the collection interval for the collection process.	Specify a value in the range from 60 to 3,600 (seconds).	
3	Std_Category	Specifies whether the collection process is to collect basic information (PI and PI_CPU records).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	
4	Disk_Category	Specifies whether the collection process is to collect disk information (PI_PDSK and PI_LDSK records).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	
5	Network_Category	Specifies whether the collection process is to collect network information (PI_NET record).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	
6	Ps_Category	Specifies whether the collection process is to collect process information (PD_APS, PD_ASVC, PD_APP2, PD_APPC, and PD_APPD records).	Specify one of the following values: <ul style="list-style-type: none"> Y: Collect N: Do not collect 	
7	RMHost_User [#]	Specifies the user account used at the PFM - RM host.	From 1 to 256 bytes of characters are permitted. The tab character is not permitted.	
8	RMHost_Password [#]	Specifies the password for the account used at the PFM - RM host. The characters entered in this item are not displayed on the screen. If you enter this password, you are prompted to re-enter the same password.	From 1 to 256 bytes of characters are permitted. The tab character is not permitted.	
9	RMHost_Domain [#]	Specifies the domain name to which the account used at the PFM - RM host belongs. There is no need to specify this item if the account belongs to a work group.	From 0 to 256 bytes of characters are permitted. The tab character is not permitted.	
10	SSH_Client	Specifies an absolute path for the execution module (plink.exe) of the SSH client (PuTTY). Even if the file path contains a space, there is no need to enclose the file path in double quotation marks ("). There is no need to specify this item if all of the monitored hosts in the instance are running Windows.	From 0 to 256 bytes of characters are permitted. The tab character is not permitted.	
11	Perl_Module	Specifies an absolute path for the execution module (perl.exe) of Perl (ActivePerl). Even if the file path contains a space, there is no need to enclose the file path in double quotation marks (").	From 0 to 256 bytes of characters are permitted. The tab character is not permitted.	

No.	Item name	Description	Setting	Default
11	Perl_Module	There is no need to specify this item if all of the monitored hosts in the instance are running Windows.	From 0 to 256 bytes of characters are permitted. The tab character is not permitted.	Previous setting
12	Log_Size	Specifies the maximum size of one agent log file.	Specify a value in the range from 1 to 32 (megabytes).	

#

These items are not displayed, depending on the environment or settings. For details about the conditions and input values that prevent these items from being displayed, see [Table 3-11](#).

To check the name of an instance, use the `jpccconf inst list` command. To update an instance environment, use the `jpccconf inst setup` command.

To update multiple instance environments, repeat the procedure described below.

To update an instance environment:

1. Check the name of the instance.

Execute the `jpccconf inst list` command with the service key that indicates PFM - RM for Platform specified.

```
jpccconf inst list -key RMPlatform
```

For example, if the set instance name is `inst1`, the command displays `inst1`.

2. If any services of PFM - RM for Platform are running in the instance environment that you want to update, stop all of them.

For details about how to stop services, see the chapter that describes starting and stopping Performance Management in the *JP1/Performance Management User's Guide*.

If a service of the instance environment that is to be updated is running during execution of the `jpccconf inst setup` command, a confirmation message is displayed to enable you to stop the service. When you stop the service, the update processing resumes. If you do not stop the service, the update processing is canceled.

3. Execute the `jpccconf inst setup` command with the service key that indicates PFM - RM for Platform and the instance name specified.

For example, to update an instance environment whose instance name is `inst1`, execute the following command:

```
jpccconf inst setup -key RMPlatform -inst inst1
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf inst setup` command in the non-interactive mode.

For details about how to execute this command in the non-interactive mode, see [3.1.4\(2\) Setting up an instance environment](#).

If you execute the `jpccconf inst setup` command in the non-interactive mode, the procedure in step 4 is not required.

4. Update the instance environment for PFM - RM for Platform.

Enter the applicable items listed in [Table 3-34 Instance environment settings for PFM - RM for Platform \(for Windows\)](#) according to the command's instructions. The current settings are displayed. To not change a displayed value, press the **Enter** key. When all entries have been made, the instance environment is updated.

5. Restart the services for the updated instance environment.

For details about how to start services, see the chapter that describes starting and stopping Performance Management in the *JPI/Performance Management User's Guide*.

For details about the commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

(2) In UNIX

To update an instance environment, check the instance name, and then update individual instance environment settings. Use the PFM - RM host to set individual instance environment settings.

Use the following table to check the information to be updated beforehand.

Table 3–35: Instance environment settings for PFM - RM for Platform (for UNIX)

No.	Item name	Description	Setting	Default
1	Interval	Specifies the collection interval for the collection process.	Specify a value in the range from 60 to 3,600 (seconds).	Previous setting
2	Std_Category	Specifies whether the collection process is to collect basic information (PI and PI_CPU records).	Specify one of the following values: <ul style="list-style-type: none">Y: CollectN: Do not collect	
3	Disk_Category	Specifies whether the collection process is to collect disk information (PI_PDSK and PI_LDSK records).	Specify one of the following values: <ul style="list-style-type: none">Y: CollectN: Do not collect	
4	Network_Category	Specifies whether the collection process is to collect network information (PI_NET record).	Specify one of the following values: <ul style="list-style-type: none">Y: CollectN: Do not collect	
5	Ps_Category	Specifies whether the collection process is to collect process information (PD_APS, PD_ASVC, PD_APP2, PD_APPC, and PD_APPD records).	Specify one of the following values: <ul style="list-style-type: none">Y: CollectN: Do not collect	
6	Log_Size	Specifies the maximum size of one agent log file.	Specify a value in the range from 1 to 32 (megabytes).	

To check the name of an instance, use the `jpccconf inst list` command. To update an instance environment, use the `jpccconf inst setup` command.

To update multiple instance environments, repeat the procedure described below.

To update an instance environment:

1. Check the name of the instance.

Execute the `jpccconf inst list` command with the service key that indicates PFM - RM for Platform specified.

```
jpccconf inst list -key RMPlatform
```

For example, if the set instance name is `inst1`, the command displays `inst1`.

2. If any services of PFM - RM for Platform are running in the instance environment that you want to update, stop all of them.

For details about how to stop services, see the chapter that describes starting and stopping Performance Management in the *JPI/Performance Management User's Guide*.

If a service of the instance environment that is to be updated is running during execution of the `jpccconf inst setup` command, a confirmation message is displayed to enable you to stop the service. When you stop the service, the update processing resumes. If you do not stop the service, the update processing is canceled.

3. Execute the `jpccconf inst setup` command with the service key that indicates PFM - RM for Platform and the instance name specified.

For example, to update an instance environment whose instance name is `inst1`, execute the following command:

```
jpccconf inst setup -key RMPlatform -inst inst1
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf inst setup` command in the non-interactive mode.

For details about how to execute this command in the non-interactive mode, see [3.2.4\(3\) Setting up an instance environment](#).

If you execute the `jpccconf inst setup` command in the non-interactive mode, the procedure in step 4 is not required.

4. Update the instance environment for PFM - RM for Platform.

Enter the applicable items listed in [Table 3-35 Instance environment settings for PFM - RM for Platform \(for UNIX\)](#) according to the command's instructions. The current settings are displayed. To not change a displayed value, press the **Enter** key. When all entries have been made, the instance environment is updated.

5. Restart the services for the updated instance environment.

For details about how to start services, see the chapter that describes starting and stopping Performance Management in the *JPI/Performance Management User's Guide*.

For details about the commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

3.6.3 Updating a monitoring target

This subsection describes how to update a monitoring target of PFM - RM for Platform while the Performance Management system is running.

(1) In Windows

To update a set monitoring target, you must first check the name of the monitoring target, and then update the monitoring target. Use the PFM - RM host to set the monitoring target.

Before you perform this operation, check the information to be updated. The following table lists and describes the information that can be updated.

Table 3–36: Monitoring target settings for PFM - RM for Platform (for Windows)

No.	Item	Description	Setting	Default value
1	Target Host	Specifies the resolvable host name where the monitoring target is run. This information is used for collection of performance data and health checking. It is also used as the	From 1 to 32 bytes of alphanumeric characters and the hyphen (-) are permitted. A name beginning with a hyphen (-) is not permitted. The host	Previous setting

No.	Item	Description	Setting	Default value
1	Target Host	event host name when JP1/IM is linked.	name must be unique within the instance.	Previous setting
2	UseCommonAccount [#]	Specifies whether to use common account information.	Specify one of the following values: <ul style="list-style-type: none"> Y: Use N: Do not use 	
3	TargetType	Specifies the method to use when connecting to the monitored host. The setting differs depending on whether the monitored host is running Windows or UNIX. For health check monitoring, the value should be icmp.	The values listed below can be set. You cannot change these settings. <ul style="list-style-type: none"> wmi: WMI (when the monitored host is running Windows) ssh: SSH (when the monitored host is running UNIX) icmp: Health check monitoring 	Initial setting
4	User [#]	Specifies the user who connects to the monitored host.	From 1 to 256 bytes of characters are permitted. The following character is not permitted: <ul style="list-style-type: none"> Tab 	Previous setting
5	Password [#]	Specifies the password needed to connect to the monitored host. The password is not displayed on the screen. If you set a password, you must enter it twice. There is no need to specify this item if the monitored host is running UNIX.	From 0 to 256 bytes of characters are permitted. The following character is not permitted: <ul style="list-style-type: none"> Tab 	
6	Domain [#]	Specifies the domain name to which the monitored host belongs. There is no need to specify this item if the monitored host belongs to a work group. There is no need to specify this item if the monitored host is running UNIX.	From 0 to 256 bytes of characters are permitted. The following character is not permitted: <ul style="list-style-type: none"> Tab 	
7	Private_Key_File [#]	Specifies an absolute path for the name of the private key file used in the SSH public key method. Even if the file path contains a space, there is no need to enclose the file path in double quotation marks (""). There is no need to specify this item if the monitored host is running Windows.	From 0 to 256 bytes of characters are permitted. The following character is not permitted: <ul style="list-style-type: none"> Tab 	
8	Port [#]	Specifies the port number of the SSH server on the monitored host. This item is not used if the monitored host is running Windows. In this case, leave the default value.	1 to 65,535	

[#]

These items are not displayed, depending on the environment or settings. For details about the conditions and input values that prevent these items from being displayed, see [Table 3-18](#).

To check the name of a monitoring target, use the `jpccnf target list` command. To check the settings for a monitoring target, use the `jpccnf target display` command. To update a monitoring target, use the `jpccnf target setup` command.

Note

There is no need to stop services of PFM - RM for Platform while you are updating a monitoring target.

To update multiple monitoring targets, repeat the procedure described below.

To update a monitoring target:

1. To check the name of the monitoring target, execute the `jpccconf target list` command with the service key that indicates PFM - RM for Platform and the instance name specified:

```
jpccconf target list -key RMPlatform -inst inst1
Targets:
targethost1
targethost2
Groups:
All
```

2. To check the settings for the monitoring target, execute the `jpccconf target display` command with the service key that indicates PFM - RM for Platform, the instance name, and the monitoring target name specified.

For example, if you want to check the settings for the monitoring target whose name is `targethost1`, execute the following command:

```
jpccconf target display -key RMPlatform -inst inst1 -target targethost1
```

3. Execute the `jpccconf target setup` command with the service key that indicates PFM - RM for Platform, the instance name, and the monitoring target name specified.

For example, if you want to update the monitoring target whose name is `targethost1`, execute the following command:

```
jpccconf target setup -key RMPlatform -inst inst1 -target targethost1
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf target setup` command in the non-interactive mode.

For details about how to execute this command in the non-interactive mode, see [3.1.4\(3\) Setting the monitored host](#).

If you execute the `jpccconf target setup` command in the non-interactive mode, the procedure in step 4 is not required.

4. To update the PFM - RM for Platform monitoring target, enter the applicable items listed in [Table 3-36 Monitoring target settings for PFM - RM for Platform \(for Windows\)](#) according to the command's instructions.

The current settings are displayed. To not change a displayed value, press the **Enter** key. When all entries have been made, the monitoring target is updated.

For details about the commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

(2) In UNIX

To update a set monitoring target, you must first check the name of the monitoring target, and then update the monitoring target. Use the PFM - RM host to set the monitoring target.

Before you perform this operation, check the information to be updated. The following table lists and describes the information that can be updated.

Table 3–37: Monitoring target settings for PFM - RM for Platform (for UNIX)

No.	Item	Description	Setting	Default value
1	Target Host	Specifies the resolvable host name where the monitoring target is run.	From 1 to 32 bytes of alphanumeric characters and the hyphen (-) are permitted. A name beginning with a hyphen (-) is not permitted. The host name must be unique within the instance.	Previous setting
2	UseCommonAccount [#]	Specifies whether to use common account information.	Specify one of the following values: <ul style="list-style-type: none"> Y: Use N: Do not use 	
3	TargetType	Specifies the method for connecting to the monitored host. If the monitored host is running UNIX, the value should be <code>ssh</code> . For health check monitoring, the value should be <code>icmp</code> .	The values listed below can be set. You cannot change these settings. <ul style="list-style-type: none"> <code>ssh</code>: SSH (when the monitored host is running UNIX) <code>icmp</code>: Health check monitoring 	Initial setting
4	User [#]	Specifies the user who logs on to the monitoring target. PFM - RM for Platform uses this user to log on to the monitored host and perform information collection.	From 1 to 256 bytes of characters are permitted. The following character is not permitted: <ul style="list-style-type: none"> Tab 	Previous setting
5	Private_Key_File [#]	Specifies the name of the private key file that is used in the SSH public key method.	From 1 to 256 bytes of characters are permitted. The following character is not permitted: <ul style="list-style-type: none"> Tab 	
6	Port	Specifies the port number of the SSH server on the monitored host.	From 1 to 65,535	

#

These items are not displayed, depending on the environment or settings. For details about the conditions and input values that prevent these items from being displayed, see [Table 3-29](#).

To check the name of a monitoring target, use the `jpccconf target list` command. To check the settings for a monitoring target, use the `jpccconf target display` command. To update a monitoring target, use the `jpccconf target setup` command.

**Note**

There is no need to stop services of PFM - RM for Platform while you are updating a monitoring target.

To update multiple monitoring targets, repeat the procedure described below.

To update a monitoring target:

1. To check the name of the monitoring target, execute the `jpccconf target list` command with the service key that indicates PFM - RM for Platform and the instance name specified:

```
jpccconf target list -key RMPlatform -inst inst1
Targets:
targethost1
targethost2
```

Groups:
All

2. To check the settings for the monitoring target, execute the `jpccconf target display` command with the service key that indicates PFM - RM for Platform, the instance name, and the monitoring target name specified.

For example, if you want to check the settings for the monitoring target whose name is `targethost1`, execute the following command:

```
jpccconf target display -key RMPlatform -inst inst1 -target targethost1
```

3. Execute the `jpccconf target setup` command with the service key that indicates PFM - RM for Platform, the instance name, and the monitoring target name specified.

For example, if you want to update the monitoring target whose name is `targethost1`, execute the following command:

```
jpccconf target setup -key RMPlatform -inst inst1 -target targethost1
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf target setup` command in the non-interactive mode.

For details about how to execute this command in the non-interactive mode, see [3.2.4\(4\) Setting the monitored host](#).

If you execute the `jpccconf target setup` command in the non-interactive mode, the procedure in step 4 is not required.

4. To update the PFM - RM for Platform monitoring target, enter the applicable items listed in [Table 3-37 Monitoring target settings for PFM - RM for Platform \(for UNIX\)](#) according to the command's instructions.

The current settings are displayed. To not change a displayed value, press the **Enter** key. When all entries have been made, the monitoring target is updated.

For details about the commands, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

3.7 Backing up and restoring PFM - RM for Platform

This section describes backing up and restoring PFM - RM for Platform.

To provide for recovery of the system in the event of a failure, you should back up the settings for PFM - RM for Platform periodically. You should also back up the settings whenever a change has been made to the system, such as whenever PFM - RM for Platform setup is performed.

For details about backup and restoration of the entire Performance Management system, see the chapter that describes backup and restoration in the *JPI/Performance Management User's Guide*.

3.7.1 Backing up

You can use any method to make a backup, such as by copying files. Always perform the backup operation while the services of PFM - RM for Platform are stopped.

(1) Files to be backed up for PFM - RM for Platform (for Windows)

The following table lists the settings files for PFM - RM for Platform that must be backed up.

For other files, see the section that presents a list of PFM - RM files to be backed up (for Windows) in the *JPI/Performance Management User's Guide*.

Table 3–38: Files to be backed up for PFM - RM for Platform (for Windows)

No.	File name	Description
1	<i>installation-folder</i> ^{#1} \agt7\agent*.ini file	Settings files for the Remote Monitor Collector service
2	<i>installation-folder</i> ^{#1} \agt7\agent\instance-name ^{#2} *.ini file	
3	<i>installation-folder</i> ^{#1} \agt7\agent\instance-name ^{#2} \groups*.ini file	
4	<i>installation-folder</i> ^{#1} \agt7\agent\instance-name ^{#2} \targets*.ini file	
5	<i>installation-folder</i> ^{#1} \agt7\agent\instance-name ^{#2} \targets*_jpcapp file ^{#3}	Application definition file
6	<i>installation-folder</i> ^{#1} \agt7\store*.ini file	Settings files for the Remote Monitor Store service
7	<i>installation-folder</i> ^{#1} \agt7\store\instance-name ^{#2} *.ini file	

#1

If you use a logical host for operation, replace *PFM-RM-for-Platform-installation-folder* with *environment-folder\jplpc*. An environment folder is a folder on the shared disk that is specified when the local host is created.

#2

These are folders used for operation in an instance environment. In the case of an instance configuration, as many folders as there are instances are created.

#3

This file exists only if application monitoring is specified.

Important

When you back up PFM - RM for Platform, you must manage the environment's product version numbers. For details about the product version numbers, see the *Release Notes*.

Before you back up PFM - RM for Platform, you must record the instances and the configuration of the monitoring targets (including the logical host environment).

(2) Files to be backed up for PFM - RM for Platform (for UNIX)

The following table lists the settings files for PFM - RM for Platform that must be backed up.

For other files, see the section that presents a list of PFM - RM files to be backed up (for UNIX) in the *JPI/Performance Management User's Guide*.

Table 3–39: Files to be backed up for PFM - RM for Platform (for UNIX)

No.	File name	Description
1	/opt ^{#1} /jplpc/agt7/agent/*.ini file	Settings files for the Remote Monitor Collector service
2	/opt ^{#1} /jplpc/agt7/agent/instance-name ^{#2} /*.ini file	
3	/opt ^{#1} /jplpc/agt7/agent/instance-name ^{#2} /groups/*.ini file	
4	/opt ^{#1} /jplpc/agt7/agent/instance-name ^{#2} /targets/*.ini file	
5	/opt ^{#1} /jplpc/agt7/agent/instance-name ^{#2} /targets/_jpcapp file ^{#3}	Application definition file
6	/opt ^{#1} /jplpc/agt7/store/*.ini file ^{#2}	Settings files for the Remote Monitor Store service
7	/opt ^{#1} /jplpc/agt7/store/instance-name ^{#2} /*.ini file	

#1

If you use a *logical* host for operation, replace `opt` with *environment-directory*. An environment directory is a directory on the shared disk that is specified when the logical host is created.

#2

These are directories used for operation in an instance environment. In the case of an instance configuration, as many directories as there are instances are created.

#3

This file exists only if application monitoring is specified.

Important

When you back up PFM - RM for Platform, you must manage the environment's product version numbers. For details about the product version numbers, see the *Release Notes*.

3.7.2 Restoring

To restore PFM - RM for Platform settings, make sure that the prerequisites listed below are satisfied, and then copy the backup files to their original locations. The settings files on the host will be overwritten by the backup settings files.

Prerequisites

- PFM - RM for Platform has already been installed.
- All services of PFM - RM for Platform have stopped.
- Instances and monitoring targets (including the logical host environment) had been set up before they were backed up.

Important

To restore settings for PFM - RM for Platform, the product version numbers must match between the environment from which the backup was made and the environment into which the backup is restored. For details about the product version numbers, see the *Release Notes*.

3.8 Settings for using a Web browser to reference manuals

You can use a Web browser to reference the Performance Management manuals. To do this, you must copy the manuals from the manuals distribution media provided with the program product to the host where PFM - Web Console is installed.

If you are running PFM - Web Console in a cluster environment, copy the manuals onto the physical hosts of both the executing and the standby systems.

3.8.1 Setup for referencing manuals

This subsection describes the setup procedure that enables you to reference manuals from Help of PFM - Web Console or from your machine's hard disk.

(1) Referencing manuals from Help of PFM - Web Console

To reference manuals from Help of PFM - Web Console:

1. Register PFM - RM in PFM - Web Console according to the PFM - Web Console setup procedure.
Perform additional setup of PFM - RM.
2. On the host where PFM - Web Console is installed, create a directory for the copies of manuals.
The following shows the directory to be created:

In Windows

PFM-Web-Console-installation-folder\doc\language-code\Help-ID-of-PFM - RM-for-Platform

In UNIX

/opt/jplpcwebcon/doc/language-code/Help-ID-of-PFM - RM-for-Platform

For details about the help ID of PFM - RM for Platform, see [B. List of Identifiers](#).

3. From the manuals distribution media, copy the files and directories into the directory that was created in step 2.
The following shows the files and directories to be copied:

For HTML manuals

In Windows

All HTML files, CSS files, and GRAPHICS folders under *applicable-drive\MAN\3021\manual-number* (such as 03004A0D)

In UNIX

All HTML files, CSS files, and GRAPHICS directories under */distribution-media -mount-point/MAN/3021/manual-number* (such as 03004A0D)

For PDF manuals

In Windows

PDF files under *applicable-drive\MAN\3021\manual-number* (such as 03004A0D)

In UNIX

PDF files under */distribution-media -mount-point/MAN/3021/manual-number* (such as 03004A0D)

Directly under the created directory, place INDEX.HTM for the HTML manuals and the PDF files themselves for the PDF manuals.

4. Restart PFM - Web Console.

(2) Referencing manuals from your machine's hard disk

Use one of the following methods to reference manuals from your machine's hard disk:

- Use `setup.exe` on the distribution media to install the manuals (in Windows only).
- Copy the HTML, CSS, PDF, and GIF files directly into a directory of your choice.

When you reference HTML manuals, use the following directory structure:

`html` (stores HTML and CSS files)

`+-+ GRAPHICS` (stores GIF files)

3.8.2 How to view manuals

To view a manual:

1. In the Main window of PFM - Web Console, click the **Help** menu in the menu bar frame.
The Help window appears.
2. Click a manual name or the **PDF** link that follows a manual name.
Clicking a manual name displays the HTML version of that manual.
Clicking a **PDF** link displays that manual in PDF format.

Notes about displaying manuals in a Web browser

In Windows, if you display an online manual from the **Start** menu, the HTML manual might be displayed in the Web browser that is already open.

4

Collecting Process Operation Status Information

This chapter explains how to use PFM - RM for Platform to collect process operation status information and monitor it on PFM - Web Console. It also provides examples of actions to take when alarms are issued.

4.1 Setup for collecting process operation status information

This section explains the setup necessary for using PFM - RM for Platform to collect process operation status information.

You set up the collection of process operation status information by using the Agents tree window of PFM - Web Console or by using commands.

If you want to collect process operation status information by using the same procedure as that used by earlier versions (earlier than 10-00) of PFM - RM for Platform, you can set it up in the Services tree window of PFM - Web Console.

4.1.1 Setup using the Agents tree

You can set up the collection of process operation status information in the Agents tree window of PFM - Web Console.

To simplify the setup operation, you can also use an application definition template.

Setup using the Agents tree is available in PFM - Web Console version 10-00 or a later version.

4.1.2 Setting up monitoring targets in the Agents tree

To set up a monitoring targets in the Agents tree:

1. Create an application.
2. Bind an alarm table to the monitoring agent.

To collect operation status information on a per-process or per-service basis, specify only a single process or service in the application when creating it. To collect operation status information on a per-application basis, specify multiple processes or services in the application when creating it.

The following subsections provide a detailed description of how to set up a monitoring target.

(1) Creating an application

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, click **Agents**.
The Agents tree window appears.
3. In the Agents tree of the navigation frame, select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
4. In the method frame, select the **Process Monitoring Settings** method.
The Process Monitoring Settings window appears.

5. To create a new application, click the **Create** button. To modify an existing application, from **Application Definitions**, select the application definition you want to modify, and then click the **Edit** button.

You cannot select a group of application definitions.

The Process Monitoring Settings > Create a New Application Definition window or the Process Monitoring Settings > Edit an Application Definition window appears.

6. To create a new application, specify an application definition name in **Application definition name**.

Application definition names and the character strings that can be specified must obey the following rules:

- The user specifies a desired application definition name. The specified application definition name is stored in the Application Name fields of the PD_APP2, PD_APPC, and PD_APPD records, and is used as the identifier for identifying a specific application. Therefore, specify a unique name for the application definition name.
- You can specify from 1 to 63 bytes of single-byte alphanumeric characters and symbols, excluding the following:
Tab (\t) \ : ; , * ? " ' < > |

- You can specify a maximum of 64 applications.

7. If you are operating in a virtual system, specify a virtual environment identifier in **Virtual environment ID**.

If you are operating in a virtual system, enter an identifier for identifying a specific virtual environment. By specifying an identifier, you can limit the monitoring targets to processes in a specific environment.

You can specify from 1 to 63 bytes of single-byte alphanumeric characters and symbols, excluding the tab character (\t). The identifier you specify is compared to the value of the `Virtual Env ID` field of the `PD_APS` record.

Note:

Make sure that the character string you enter in **Virtual environment ID** matches what is entered in the `Virtual Env ID` field of the `PD_APS` record.

Any character in the information to be acquired that is not in the ASCII character set range of 0x20 to 0x7E will be converted to a hash mark (#; 0x23) before it is stored in the `Virtual Env ID` field of the `PD_APS` record. Note that multi-byte characters are processed in single-byte units during conversion. For example, the multi-byte (full-width) letter `A` is converted as follows:

Information to be acquired		Information after conversion	
Character encoding	Binary	Binary	Character string
Shift-JIS	8260	2360	#`
EUC	A3C1	2323	##
UTF-8	EFBCA1	232323	###

8. Specify detailed information for the application.

The following table shows the detailed information that you can specify in the Process Monitoring Settings > Create a New Application Definition window or the Process Monitoring Settings > Edit an Application Definition window.

Table 4–1: Detailed application information that can be specified

Setting	Description	Field name in the corresponding record
Name ^{#1}	Enter a condition for identifying a specific monitoring target. You can specify a maximum of 4,096 bytes of single-byte alphanumeric characters and symbols, excluding the tab character (\t).	Monitoring Condition field of the <code>PD_APPD</code> record
Label	Specify a label for identifying a specific monitoring condition. You can specify a maximum of 31 bytes of single-byte alphanumeric characters and symbols, excluding the tab character (\t). The default is <code>MonitoringXX</code> ^{#2} . If you do not enter any value, the default <code>MonitoringXX</code> ^{#2} is set. Specify a unique name for the monitoring label.	Monitoring Label field of the <code>PD_APPC</code> and <code>PD_APPD</code> records
Type	Select Program , Command Line , Service , or No selection . <ul style="list-style-type: none"> • Program The specified value is evaluated using the value of the <code>Program Name</code> field of the <code>PD_APS</code> record. • Command Line The specified value is evaluated using the value of the <code>Command Line</code> field of the <code>PD_APS</code> record. • Service The specified value is evaluated using the value of the <code>Service Name</code> field of the <code>PD_ASVC</code> record. • No selection 	Monitoring Field field of the <code>PD_APPD</code> record

Setting	Description	Field name in the corresponding record
Type	No evaluation.	Monitoring Field field of the PD_APPD record
Minimum ^{#3}	Enter the lower threshold value for the number of applications to be monitored. You can specify a value from 0 to 65535. The default is 0.	Monitoring Min field of the PD_APPD record
Maximum	Enter the upper threshold value for the number of applications to be monitored. You can specify a value from 0 to 65535. However, you must specify a value that is greater than or equal to the value specified for Minimum . The default is 0.	Monitoring Max field of the PD_APPD record

#1

- You can use the wildcard characters * and ? when specifying a name.

An asterisk (*) represents zero or more instances of any character, and a question mark (?) represents any single character.

If the monitoring target process' command line itself contains characters such as an asterisk (*) or a question mark (?), you cannot specify a monitoring condition based on complete matching.

For example, suppose that the three processes listed below exist. If you enter /bin/sample "*" as the monitoring condition, the * in the monitoring condition is treated as a wildcard, and as a result all three processes are considered to match the monitoring condition.

- /bin/sample ""
- /bin/sample "abc"
- /bin/sample "def"
- Note the following if you specify a **Name** of 128 bytes or more as a monitoring condition when setting up collection of process operation status information: The Monitoring Condition field of the PD_APPD record will display only the first 127 bytes of the specified monitoring condition. However, monitoring will occur using the complete specified monitoring condition.
- When the OS of the monitored host is Windows, the monitoring condition specified for **Name** is not case-sensitive when used to identify monitoring targets in the default setting. When the OS of the monitored host is UNIX, on the other hand, the monitoring condition specified in **Name** is case-sensitive when used to identify monitoring targets in the default setting. For details about how to specify whether the monitoring condition will be case-sensitive when identifying monitoring targets, see [4.1.12 Specifying whether process or service names to be used as monitoring targets will be case-sensitive](#).
- When the OS of the monitored host is Windows, if you select **Program** for **Type**, specify the Windows program extension (such as .exe) for **Name**.
- Make sure that the character string you enter in **Name** matches what is entered in the Program Name field of the PD_APS record, the Command Line field of the PD_APS record, and the Service Name field of the PD_ASVC record.

Any character in the information to be acquired that is not in the ASCII character set range of 0x20 to 0x7E will be converted to a hash mark (#; 0x23) before it is stored in the Program Name field of the PD_APS record, the Command Line field of the PD_APS record, and the Service Name field of the PD_ASVC record. Note that multi-byte characters are processed in single-byte units during conversion. For example, the multi-byte (full-width) letter A is converted as follows:

Information to be acquired		Information after conversion	
Character encoding	Binary	Binary	Character string
Shift-JIS	8260	2360	#`
EUC	A3C1	2323	##
UTF-8	EFBCA1	232323	###

#2

A value from 01 to 15 is set for *XX*. A numeric value corresponding to the Monitoring Number field of the PD_APPC and PD_APPD records is set.

#3

To monitor a process that generates child processes, specify an appropriate numeric value by referring to [9.2.4 Alarms related to process monitoring are not reported as intended](#).

Note

From the **Input support** > **Agent** pull-down menu, select a remote agent for a monitored host and click the **Add** button. The Process Monitoring Settings > Create a New Application Definition > Add from *monitoring-targets* window[#] or the Process Monitoring Settings > Edit an Application Definition > Add from *monitoring-target* window[#] appears. You can then select a process and set up its properties.

#

For *monitoring-targets*, **Running Process**, **Running Command Lines**, or **Services** is displayed depending on what is specified for **Type** in the Process Monitoring Settings > Create a New Application Definition window or the Process Monitoring Settings > Edit an Application Definition window.

If you selected **Program** for **Type** in these windows, **Running Processes** is displayed. If you selected **Command Line**, **Running Command Lines** is displayed. If you selected **Service**, **Services** is displayed. By default, **Running Processes** is displayed.

9. Click the **OK** button.

The settings you specified take effect.

Shown below is the procedure for setting up properties from the Process Monitoring Settings > Create a New Application Definition > Add from *monitoring-target* window[#] or the Process Monitoring Settings > Edit an Application Definition > Add from *monitoring-target* window[#] in steps 8 and beyond under [\(1\) Creating an application](#).

#

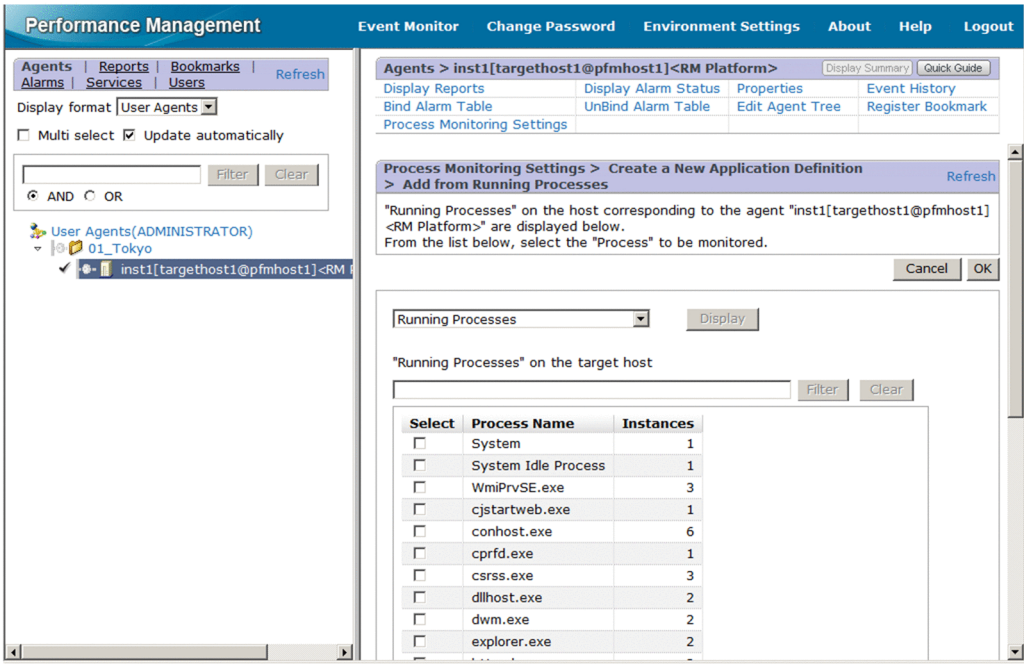

For the monitoring target type, **Running Processes**, **Running Command Lines**, or **Services** is displayed depending on what is specified for **Type** in the Process Monitoring Settings > Create a New Application Definition window or the Process Monitoring Settings > Edit an Application Definition window.

If you selected **Program** for **Type** in these windows, **Running Processes** is displayed. If you selected **Command Line**, **Running Command Lines** is displayed. If you selected **Service**, **Services** is displayed. By default, **Running Processes** is displayed.

10. Execute steps 1 through 7 in [\(1\) Creating an application](#).

11. From **Input support** > **Agent** pull-down menu, select a remote agent for the monitored host and click the **Add** button.

The Process Monitoring Settings > Create a New Application Definition > Add from *monitoring-target* window or the Process Monitoring Settings > Edit an Application Definition > Add from *monitoring-target* window appears.

12. From the pull-down menu on the left side of the **Display** button, select a monitoring target type (**Running Processes**, **Running Command Lines**, or **Services**) and click the **Display** button.
- A process list is displayed at the bottom of the Process Monitoring Settings > Create a New Application Definition > Add from *monitoring-target* window or the Process Monitoring Settings > Edit an Application Definition > Add from *monitoring-target* window.
- In the process list, by specifying a keyword in **Filter** and clicking the **Search** button, you can display only those processes that include the keyword in their process names. Clicking the **Clear** button will take you back to the original process list.
13. From the process list, select the process you want to monitor and click the **OK** button.
- The Process Monitoring Settings > Create a New Application Definition > Add from *monitoring-target* window or the Process Monitoring Settings > Edit an Application Definition > Add from *monitoring-target* window closes, and the display will return to the Process Monitoring Settings > Create a New Application Definition window or the Process Monitoring Settings > Edit an Application Definition window.
14. Modify the necessary items in the displayed window.
- For details about the settings, see [Table 4-1 Detailed application information that can be specified](#).
15. Click the **OK** button.
- The new settings take effect.

(2) Binding an alarm table to the monitoring agent

Bind an alarm table for monitoring the operation status information to the monitoring agent. The alarm for monitoring the operation status information is called the Application Status alarm. Edit it as needed. For details about this alarm, see [Application Status](#) in [6. Monitoring Template](#). If you monitor a process that generates child processes, specify an alarm-reporting method by referring to [9.2.4 Alarms related to process monitoring are not reported as intended](#).

You can use one of the following two methods to bind an alarm table:

- Binding the alarm table PFM RM Platform Template Alarms [APP] 09.10
- Binding a user-created alarm table

To bind the alarm of PFM RM Platform Template Alarms [APP] 09.10:

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, click **Agents**.
The Agents tree window appears.
3. In the Agents tree of the navigation frame, select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
4. In the method frame, select the **Process Monitoring Settings** method.
The Process Monitoring Settings window appears.
5. Click the **Start** button for **Process monitoring alarm settings**.
The alarm table is bound to the monitoring agent.

To bind a user-created alarm table:

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, click **Agents**.
The Agents tree window appears.
3. In the Agents tree of the navigation frame, select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
4. In the method frame, select **Bind Alarm Table**.
The Bind Alarm Table [Select Alarm Table] window appears.
5. Select an alarm table displayed under the **RM Platform** folder and click the **OK** button.
The alarm table is bound to the monitoring agent.

If you want to monitor the status of a specific process only, you can create an alarm based on one of the following conditional expressions for monitoring.

Table 4–2: Conditional expression for monitoring a specific process only

Item	Conditional expression
Record	Application Process Count (PD_APPC)
Field	Application Name Monitoring Label Monitoring Status
Abnormal and warning conditions ^{#1}	Application Name = <i>Name</i> ^{#2} AND Monitoring Label = <i>Label</i> ^{#2} AND Monitoring Status = ABNORMAL

#1

For the abnormal and warning conditions, specify the same condition.

#2

Specify the application name to be monitored and a monitoring label.

4.1.3 Deleting monitoring target settings in Agents tree

To delete a monitoring target in the Agents tree:

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, click **Agents**.
The Agents tree window appears.
3. In the Agents tree of the navigation frame, select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
4. In the method frame, select the **Process Monitoring Settings** method.
The Process Monitoring Settings window appears.
5. From **Application Definitions**, select the application definition you want to delete and click the **Delete** button.
The Process Monitoring Settings > Delete an Application Definition window appears.
6. Click the **OK** button.
The setting is deleted.

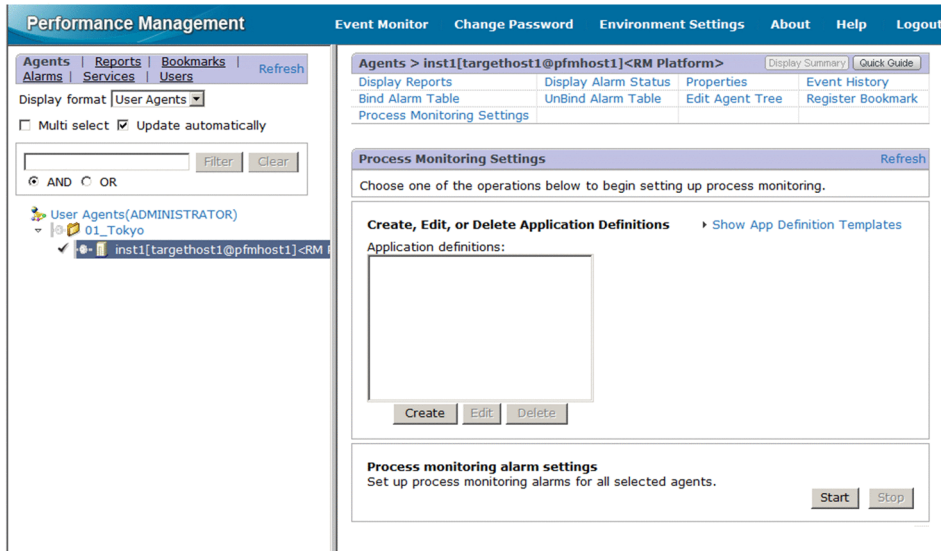

4.1.4 Using an application definition template in the Agents tree

You can save the setting for collecting process operation status information (application definition) that was specified in the Agents tree window of PFM - Web Console as a template and use it in multiple machines.

This subsection explains how to create, delete, and load an application definition template.

(1) Creating an application definition template

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, click **Agents**.
The Agents tree window appears.
3. In the Agents tree of the navigation frame, select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
4. In the method frame, select the **Process Monitoring Settings** method.
The Process Monitoring Settings window appears.

5. Select the **Show App Definition Templates** menu.

The **Edit Templates** menu appears.

6. Select the **Edit Templates** menu.

The Process Monitoring Settings > Application Definition Templates window appears.

7. To create a new template, click the **Create** button. To modify settings, select the template you want to modify from **Application Definition Templates** and click the **Edit** button.

The Process Monitoring Settings > Create a New Application Definition Template window or the Process Monitoring Settings > Edit an Application Definition Template window appears.

8. Enter a template name in **Template name**.
9. Enter a template description in **Description**.
10. Specify detailed information for the application.
For details about the settings, see [Table 4-1 Detailed application information that can be specified in 4.1.2\(1\) Creating an application](#).
11. Click the **OK** button.
An application definition template is created.

(2) Deleting an application definition template

1. From the browser of the monitoring console, log in to PFM - Web Console.

The Main window appears.

2. In the navigation frame of the Main window, click **Agents**.

The Agents tree window appears.

3. In the Agents tree of the navigation frame, select a remote agent (*device-ID<product-name>*).

A check mark is displayed for the selected remote agent.

4. In the method frame, select the **Process Monitoring Settings** method.

The Process Monitoring Settings window appears.

5. Select the **Show App Definition Templates** menu.

The **Edit Templates** menu appears.

6. Select the **Edit Templates** menu.

The Process Monitoring Settings > Application Definition Templates window appears.

7. From **Application Definition Templates**, select the template you want to delete and click the **Delete** button.

The Process Monitoring Settings > Delete an Application Definition Template window appears.

8. Click the **OK** button.

The application definition template is deleted.

(3) Loading an application definition template

1. From the browser of the monitoring console, log in to PFM - Web Console.

The Main window appears.

2. In the navigation frame of the Main window, click **Agents**.

The Agents tree window appears.

3. In the Agents tree of the navigation frame, select a remote agent (*device-ID<product-name>*).

A check mark is displayed for the selected remote agent.

4. In the method frame, select the **Process Monitoring Settings** method.

The Process Monitoring Settings window appears.

5. Click the **Create** button.

The Process Monitoring Settings > Create a New Application Definition window appears.

6. Click the **Load Template** button.

The Process Monitoring Settings > Create a New Application Definition > Input Using Application Definition Template window appears.

7. Select the template you want to load from **Application Definition Templates** and click the **Select** button.
The application definition template is loaded.

4.1.5 Setting up collection in Services

If you want to specify the collection of process operation status information using the same procedure that was used in an earlier versions of PFM - RM for Platform (earlier than 10-00), you can do so in the Services window of PFM - Web Console.

4.1.6 Setting up a monitoring target in Services

To set up a monitoring target in Services:

1. Create an application.
2. Specify application properties (the name of the application to be monitored and a threshold value).
3. Bind an alarm table to the monitoring agent.[#]

#

To bind an alarm table, use the Agents tree window of PFM - Web Console.

To collect operation status information on a per-process or per-service basis, specify only a single process or service when creating the application. To collect operation status information on a per-application basis, specify multiple processes or services when creating the application.

The following subsections provide a detailed description of how to set up a monitoring target.

(1) Creating an application

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, select the **Services** tab.
The Services window appears.
3. From the navigation frame, expand the hierarchy under the **Machines** folder.

A folder with the name of the host on which Performance Management service is installed appears. When you expand the folder with the host name, the services installed on this host appear.

The name of each service is displayed as a service ID. For details about service IDs, see [B. List of Identifiers](#) and the section that describes service-naming rules in the appendix of the *JPI/Performance Management Planning and Configuration Guide*.

The service ID format differs depending on whether the product name display function is enabled. For details about this function, see the chapter that describes the functions of Performance Management in the *JPI/Performance Management Planning and Configuration Guide*.

- Expand the hierarchy under the monitoring agent host's folder and select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
- In the method frame, select the **Properties** method.
The Service Properties window appears.
- Under the **Remote Monitor Configuration** tree, select the **ADDITION OR DELETION A SETTING** tree.
- On the bottom of the information frame, specify an application name in **ADD AN APPLICATION MONITORING SETTING**.

The following rules apply to application names and the character string that can be specified:

- The user specifies a desired application name. The specified application name is stored in the *Application Name* fields of the *PD_APP2*, *PD_APPC*, and *PD_APPD* records, and is used as the identifier for identifying a specific application. Therefore, specify a unique name for the application name.
- You can specify from 1 to 63 bytes of single-byte alphanumeric characters and symbols, excluding the following:
Tab (\t) \ : ; , * ? " ' < > |
- You can specify a maximum of 64 applications.

- Click the **OK** button.
In the Service Properties window, under the **Remote Monitor Configuration - Application monitoring setting** tree, an application name tree is generated.

(2) Specifying application properties

- After you have performed the procedure in [\(1\) Creating an application](#), open the Service Properties window again and select an application name generated under the **Remote Monitor Configuration - Application monitoring setting** tree.
A window for entering property information appears at the bottom of the information frame.

- Specify properties.
Specify a virtual environment identifier, a monitoring label, a monitoring field, a monitoring condition, and the minimum and maximum threshold values for the number of monitoring targets. You can specify multiple pieces of process information. The following table lists and describes the properties.

Table 4–3: Application property settings

Item	Property name	Description	Field name in the corresponding record
Virtual environment identifier	Virtual Environment ID#1	If you are operating on a virtual system, enter an ID for identifying a specific virtual environment. By specifying this item, you can restrict the operation to processes in a specific environment.	Virtual Env ID field of the PD_APP2 record

Item	Property name	Description	Field name in the corresponding record
Virtual environment identifier	Virtual Environment ID ^{#1}	You can specify from 1 to 63 bytes of single-byte alphanumeric characters and symbols, excluding the tab character (\t). The identifier you specify is compared to the value of the Virtual Env ID field of the PD_APS record.	Virtual Env ID field of the PD_APP2 record
Monitoring label	MonitoringXX Label	Specify a label for identifying a specific monitoring condition. You can specify a maximum of 31 bytes of single-byte alphanumeric characters and symbols, excluding the tab character (\t). The default is MonitoringXX ^{#2} . If you do not enter any value, the default MonitoringXX ^{#2} is set. Specify a unique name for the monitoring label.	Monitoring Label field of the PD_APPC and PD_APPD records
Monitoring field	MonitoringXX Field	Select Program Name , Command Line , Service Name , or None . <ul style="list-style-type: none"> • Program Name The specified value is compared to the value of the Program Name field of the PD_APS record. • Command Line The specified value is compare to the value of the Command Line field of the PD_APS record. • Service Name The specified value is compared to the value of the Service Name field of the PD_ASVC record. • None No evaluation. The default is None .	Monitoring Field field of the PD_APPD record
Monitoring condition ^{#3}	MonitoringXX Condition	Enter a condition for identifying a specific monitoring target. You can specify a maximum of 4,096 bytes of single-byte alphanumeric characters and symbols, excluding the tab character (\t). The default is one space.	Monitoring Condition field of the PD_APPD record
Minimum and maximum threshold values for the number of monitoring targets ^{#4}	MonitoringXX Range	Enter the lower and upper threshold values for the number of monitoring targets by connecting the two values with a hyphen (-), such as 1-2. You can specify from 0 to 65535. The default is 0-0.	<ul style="list-style-type: none"> • Minimum value Monitoring Min field of the PD_APPD record • Maximum value Monitoring Max field of the PD_APPD record

#1

For the Virtual Environment ID property, you must check the Virtual Env ID field of the PD_APS record and enter the same character string as that specified in this field.

#2

A value from 01 to 15 is set for *XX*. A numeric value corresponding to the Monitoring Number field of the PD_APPC and PD_APPD records is set.

#3

- You can use the wildcard characters * and ? when specifying a condition.

An asterisk (*) represents zero or more instances of any character, and a question mark (?) represents any single character.

If the monitoring target process' command line itself contains characters such as an asterisk (*) or a question mark (?), you cannot specify a monitoring condition based on complete matching.

For example, suppose that the three processes listed below exist. If you enter /bin/sample "*" as the monitoring condition, the * in the monitoring condition is treated as a wildcard, and as a result all three processes are considered to match the monitoring condition.

- /bin/sample ""
- /bin/sample "abc"
- /bin/sample "def"
- Note the following if you specify 128 bytes or more characters for the monitoring condition (Monitoring*XX* Condition) when setting up collection of process operation status information: The Monitoring Condition field of the PD_APPD record will display only the first 127 bytes of the specified monitoring condition. However, monitoring will occur using the complete specified monitoring condition.
- When the OS of the monitored host is Windows, the monitoring condition is not case-sensitive when identifying monitoring targets in the default setting. In contrast, when the OS of the monitored host is UNIX, the monitoring condition is case-sensitive when identifying monitoring targets in the default setting. For details about how to specify whether the monitoring condition will be case-sensitive when identifying monitoring targets, see [4.1.12 Specifying whether process or service names to be used as monitoring targets will be case-sensitive](#).
- When the OS of the monitored host is Windows, if you specify **Program Name** for the Monitoring*XX*Field property, specify the Windows program extension (such as .exe) for the Monitoring*XX*Condition property.
- Make sure that the character string you enter in the Monitoring*XX*Condition property matches what is entered in the Program Name field of the PD_APS record, the Command Line field of the PD_APS record, and the Service Name field of the PD_ASVC record.

Any character in the information to be acquired that is not in the ASCII character set range of 0x20 to 0x7E will be converted to a hash mark (#: 0x23) before it is stored in the Program Name field of the PD_APS record, the Command Line field of the PD_APS record, the Service Name field of the PD_ASVC record, and the Virtual Env ID field of the PD_APS record. Note that multi-byte characters are processed in single-byte units during conversion. For example, the multi-byte (full-width) letter A is converted as follows:

Information to be acquired		Information after conversion	
Character encoding	Binary	Binary	Character string
Shift-JIS	8260	2360	#`
EUC	A3C1	2323	##
UTF-8	EFBCA1	232323	###

#4

To monitor a process that generates child processes, specify a maximum value by referring to [9.2.4 Alarms related to process monitoring are not reported as intended](#).

3. Click the **OK** button.
The settings you specified take effect.

(3) Binding an alarm table to the monitoring agent

Bind an alarm table for monitoring the operation status information to the monitoring agent.

The alarm for monitoring the operation status information is called the Application Status alarm. Edit it as needed.

For details about this alarm, see *Application Status* in *6. Monitoring Template*.

If you monitor a process that generates child processes, specify an alarm-reporting method by referring to *9.2.4 Alarms related to process monitoring are not reported as intended*.

To bind an alarm table:

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, click **Agents**.
The Agents tree window appears.
3. In the Agents tree of the navigation frame, select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
4. In the method frame, select **Bind Alarm Table**.
The Bind Alarm Table [Select Alarm Table] window appears.
5. Select an alarm table displayed under the **RM Platform** folder and click the **OK** button.

If you want to monitor the status of one specific process only, you can create an alarm based on one of the following conditional expressions for monitoring.

Table 4–4: Conditional expression for monitoring a specific process only

Item	Conditional expression
Record	Application Process Count (PD_APPC)
Field	Application Name Monitoring Label Monitoring Status
Abnormal and warning conditions ^{#1}	Application Name = <i>Name</i> ^{#2} AND Monitoring Label = <i>Label</i> ^{#2} AND Monitoring Status = ABNORMAL

#1
For the abnormal and warning conditions, specify the same condition.

#2
Specify the application name to be monitored and a monitoring label.

4.1.7 Checking or modifying the settings for monitoring targets in Services

To check or modify the settings for monitoring targets in Services:

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, select the **Services** tab.
The Services window appears.
3. From the navigation frame, expand the hierarchy under the **Machines** folder.
A folder with the name of the host on which Performance Management service is installed appears. When you expand the folder with the host name, the services installed on this host appear.
The name of each service is displayed as a service ID. For details about service IDs, see [B. List of Identifiers](#) and the section that describes service-naming rules in the appendix of the *JPI/Performance Management Planning and Configuration Guide*.
The service ID format differs depending on whether the product name display function is enabled. For details about this function, see the chapter that describes the functions of Performance Management in the *JPI/Performance Management Planning and Configuration Guide*.
4. Expand the hierarchy under the monitoring agent host's folder and select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
5. In the method frame, select the **Properties** method.
The Service Properties window appears.
6. Expand the **Remote Monitor Configuration - Application monitoring setting** tree and select the tree with the application name you want to check.
7. Check the setting content.
8. To update the setting content, follow step 2 in [4.1.6\(2\) Specifying application properties](#).
9. Click the **OK** button.
If you update the setting details in step 8, the new content goes into effect.

4.1.8 Deleting the settings for monitoring targets in Services

To delete the settings for monitoring targets in Services:

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, select the **Services** tab.
The Services window appears.
3. From the navigation frame, expand the hierarchy under the **Machines** folder.
A folder with the name of the host on which Performance Management service is installed appears. When you expand the folder with the host name, the services installed on this host appear.

The name of each service is displayed as a service ID. For details about service IDs, see [B. List of Identifiers](#) and the section that describes service-naming rules in the appendix of the *JPI/Performance Management Planning and Configuration Guide*.

The service ID format differs depending on whether the product name display function is enabled. For details about this function, see the chapter that describes the functions of Performance Management in the *JPI/Performance Management Planning and Configuration Guide*.

4. Expand the hierarchy under the monitoring agent host's folder and select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
5. In the method frame, select the **Properties** method.
The Service Properties window appears.
6. Under the **Remote Monitor Configuration** tree, select the **ADDITION OR DELETION A SETTING** tree.
7. On the bottom of the information frame, from **DELETE AN APPLICATION MONITORING SETTING**, select the application name of the monitoring target you want to delete and click the **OK** button.
The setting content is deleted.

4.1.9 Setup using non-interactive commands

You can set up the collection of process operation status information by executing commands.

You can also set up the collection of process operation status information in the Agents tree window of PFM - Web Console. However, when you use commands, batch processing can automate the setup tasks during maintenance, for example.

4.1.10 Using commands to set up monitoring targets

To use commands to set up monitoring targets:

1. Create an application definition file.
2. Create an application.
3. Bind an alarm table to the monitoring agent.

To collect operation status information on a per-process or per-service basis, specify only a single process or service when creating the application. To collect operation status information on a per-application basis, specify multiple processes or services when creating the application.

The subsections below provide a detailed description of how to set up a monitoring target.

For details about the `jpcmkkey`, `jpcprocdef create`, `jpcprocdef output`, and `jpctool alarm bind` commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

The service ID differs depending on various conditions such as the instance name, monitoring target name, and PFM - RM host name. For example, if the instance name is `inst1`, the monitoring target is `targethost1`, and the PFM - RM host name is `lhost1`, the service ID becomes `7A1inst1[targethost1@lhost1]`. For details about service IDs, see the section that describes service-naming rules in the appendix of the *JPI/Performance Management Planning and Configuration Guide*.

(1) Creating an authentication key file

On the host on which PFM - Web Console is installed, create an authentication key file by executing the `jpcmkkey` command.

This step is not necessary if an authentication key file has already been created.

The following is an example of command execution that creates an authentication key file when `ADMINISTRATOR` is the user name to be used for login authentication and `xxxxx` is the password used during execution:

```
jpcmkkey -user "ADMINISTRATOR" -password "xxxxx"
```

(2) Creating an application definition file

Describe the conditions necessary for collecting the process operation status information in an application definition file (XML format). The application definition file is used as the parameter file for the `jpcprocdef create` command during application creation.

Execute this command by logging in to the host on which PFM - Web Console is installed.

If you are creating a new application definition file, you can use the sample shown below as a template.

When PFM - Web Console is running under Windows

```
PFM - Web-Console-installation-folder\sample\processmonitoringcommand\jpcprocdef-parameters-windows.xml
```

When PFM - Web Console is running under UNIX

```
/opt/jp1pcwebcon/sample/processmonitoringcommand/jpcprocdef-parameters-unix.xml
```

If an application definition already exists and you want to edit its content to create a new application definition, output it by executing the `jpcprocdef output` command.

Execute this command by logging in to the host on which PFM - Web Console is installed.

Examples of how to specify the `jpcprocdef output` command are shown below.

To output the application definition to `c:\sample.xml` when PFM - Web Console is running under Windows:

```
jpcprocdef output -agent service-ID -name application1 -f c:\sample.xml
```

To output the application definition to `/tmp/sample.xml` when PFM - Web Console is running under UNIX:

```
jpcprocdef output -agent service-ID -name application1 -f /tmp/sample.xml
```

(3) Creating an application

Specify an application definition file for the `-f` option and execute the `jpcprocdef create` command to create an application.

Execute the `jpcprocdef create` command by logging in to the host on which PFM - Web Console is installed. The `jpcprocdef create` command creates an application for a single agent. To create an application for multiple agents, repeatedly execute the command using a batch process. Examples of how to specify the `jpcprocdef create` command are shown below.

When PFM - Web Console is running under Windows and the application definition setting information file is `c:\sample.xml`

```
jpcprocdef create -agent service-ID -f c:\sample.xml
```

When PFM - Web Console is running under UNIX and the application definition setting information file is `/tmp/sample.xml`

```
jpcprocdef create -agent service-ID -f /tmp/sample.xml
```

(4) Binding an alarm table to the monitoring agent

Bind an alarm table for monitoring the operation status information to the monitoring agent by executing the `jpctool alarm bind` command.

Execute this command by logging in to the host on which PFM - Manager is installed.

The alarm for monitoring the operation status information is called the Application Status alarm. Edit it as needed. For details about this alarm, see [Application Status](#) in [6. Monitoring Template](#).

If an alarm table has already been bound, there is no need to bind it every time you set up a monitoring target.

You can use one of the following two methods to bind an alarm table:

- Binding the alarm table PFM RM Platform Template Alarms [APP] 09.10
- Binding a user-created alarm table

An example of specifying the `jpctool alarm bind` command for binding the alarm table PFM RM Platform Template Alarms [APP] 09.10 follows:

```
jpctool alarm bind -key RMPlatform -table "PFM RM Platform Template Alarms  
[APP] 09.10" -id service-ID -add
```

An example of specifying the `jpctool alarm bind` command for binding for binding a user-created alarm table follows:

```
jpctool alarm bind -key RMPlatform -table user-created-alarm-table-name# -id  
service-ID -add
```

#

For *user-created-alarm-table-name*, you can specify the name of any user-created alarm table.

If you want to monitor the status of a specific process only, you can create an alarm based on conditional expressions. For details about the conditional expression for monitoring only one specific process, see [Table 4-2 Conditional expression for monitoring a specific process only](#) in [4.1.2\(2\) Binding an alarm table to the monitoring agent](#).

4.1.11 Using commands to delete settings for a monitoring target

To use commands to delete settings for a monitoring target:

1. Check the definition name of the application definition you want to delete.
2. Unbind the alarm table.

3. Delete the application definition.

For details about the `jpcmkkey`, `jpcprocdef list`, `jpctool alarm unbind`, and `jpcprocdef delete` commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

The service ID differs depending on various conditions such as the instance name, monitoring target name, and PFM - RM host name. For example, if the instance name is `inst1`, the monitoring target is `targethost1`, and the PFM - RM host name is `lhost1`, the service ID becomes `7A1inst1[targethost1@lhost1]`. For details about service IDs, see the section that describes service-naming rules in the appendix of the *JPI/Performance Management Planning and Configuration Guide*.

(1) Creating an authentication key file

On the host on which PFM - Web Console is installed, create an authentication key file by executing the `jpcmkkey` command.

This step is not necessary if an authentication key file has already been created.

The following example shows a command execution that creates an authentication key file when `ADMINISTRATOR` is the user name to be used for login authentication and `xxxxxx` is the password used during execution:

```
jpcmkkey -user "ADMINISTRATOR" -password "xxxxxx"
```

(2) Checking the definition name of the application definition to be deleted

You can check the definition name of the application definition you want to delete from the list of application definitions defined in the monitoring agent by executing the `jpcprocdef list` command.

Execute the `jpcprocdef list` command by logging in to the host on which PFM - Web Console is installed. An example of how to specify this command follows:

```
jpcprocdef list -agent service-ID
```

(3) Unbinding the alarm table

Unbind the alarm table that is bound to the monitoring agent and stop any monitoring by executing the `jpctool alarm unbind` command.

Execute this command by logging in to the host on which PFM - Web Console is installed.

If the alarm table has already been unbound, there is no need to unbind it every time you delete a setting of a monitoring target.

An example of how to specify the `jpctool alarm unbind` command for unbinding the alarm table PFM RM Platform Template Alarms [APP] 09.10 follows:

```
jpctool alarm unbind -key RMPlatform -table "PFM RM Platform Template  
Alarms [APP] 09.10" -id service-ID
```

(4) Deleting the application definition

Delete the application definition by executing the `jpcprocdef delete` command.

Execute this command by logging in to the host on which PFM - Web Console is installed.

The `jpcprocdef delete` command deletes an application definition for a single agent. To delete application definitions for multiple agents, repeatedly execute the command using a batch process.

An example of how to specify the `jpcprocdef delete` command for deleting application definition `application5` follows:

```
jpcprocdef delete -agent service-ID -name "application5"
```

4.1.12 Specifying whether process or service names to be used as monitoring targets will be case-sensitive

You can specify whether process or service names to be used as monitoring targets will be case-sensitive.

If the OS of the monitored host is Windows, the names are not case-sensitive by default. If the OS of the monitored host is UNIX, the names are case-sensitive by default.

To specify whether the process or service names to be used as monitoring targets will be case-sensitive:

1. From the browser of the monitoring console, log in to PFM - Web Console.
The Main window appears.
2. In the navigation frame of the Main window, select the **Services** tab.
The Services window appears.
3. In the Services window, select a remote agent (*device-ID<product-name>*).
A check mark is displayed for the selected remote agent.
4. In the method frame, select the **Properties** method.
The Service Properties window appears.
5. Select the **Remote Monitor Configuration - Application monitoring setting** tree.
The window for entering property information appears at the bottom of the information frame.
6. Change the value of the **Case Sensitive** property.
Select either of the following:
 - **Yes**: Case-sensitive
 - **No**: Not case-sensitive
7. Click the **OK** button.
The setting is applied.

The following table shows the differences in actions based on the value of the **Case Sensitive** property.

Table 4–5: Differences in actions based on the value of the Case Sensitive property

Name of the process that is running	MonitoringXX Condition property setting	Case Sensitive property setting	Number of processes
• ProcessA	ProcessA	Yes	1

Name of the process that is running	MonitoringXX Condition property setting	Case Sensitive property setting	Number of processes
• PROCESSA	ProcessA	No	2
	PROCESSA	Yes	1
		No	2
	processa	Yes	0
		No	2

Legend:

Yes: Case-sensitive

No: Not case-sensitive

The above table shows differences in the number of processes that are judged to be running based on the settings of the `MonitoringXXCondition` and `Case Sensitive` properties in an environment in which two kinds of processes (`ProcessA` and `PROCESSA`) are running on the monitored host.

Note:

The setting of the `Case Sensitive` property affects all application definitions. Therefore, if you change the setting of the `Case Sensitive` property, check, and if necessary, revise the existing application definitions.

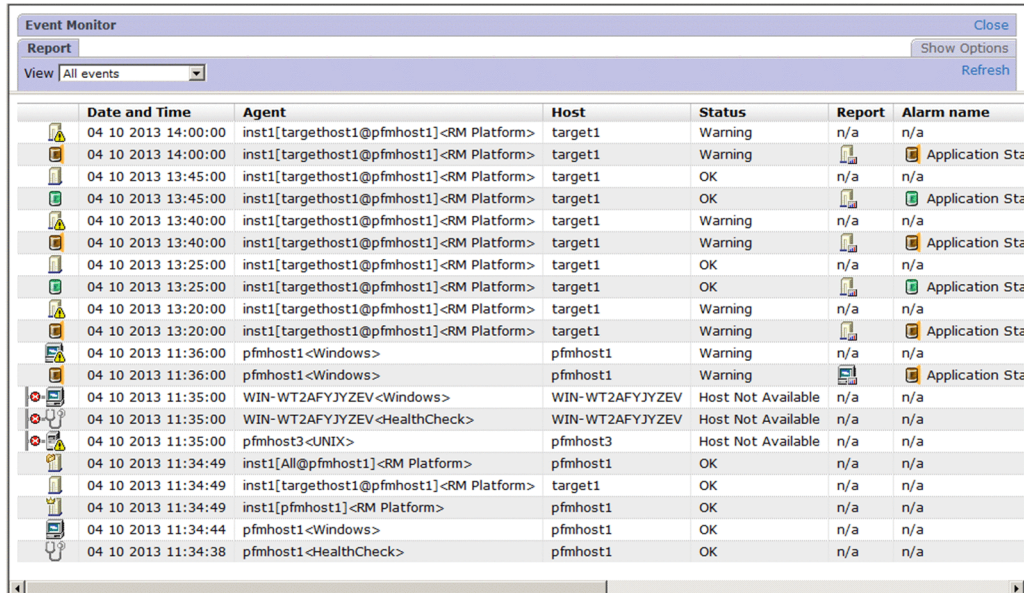

4.2 Example of the procedure to follow when an alarm is issued during the collection of process operation status information

This section shows an example of the procedure to identify the process that resulted in a warning if an alarm is issued when the collection of process operation status information is set.

For details about alarms and reports, see [6. Monitoring Template](#).

1. In the menu bar frame of the Main window, select the **Event Monitor** menu.

The Event Monitor window appears.

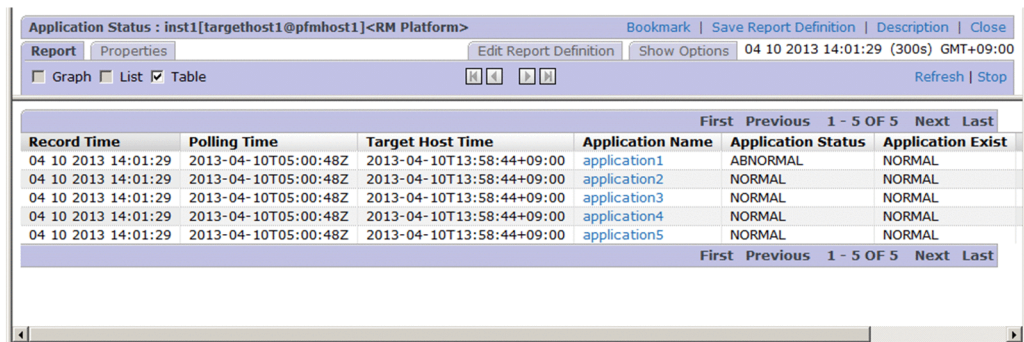

The Event Monitor window displays a table of events. The table has columns: Date and Time, Agent, Host, Status, Report, and Alarm name. The events are listed in chronological order from top to bottom.

Date and Time	Agent	Host	Status	Report	Alarm name
04 10 2013 14:00:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	Warning	n/a	n/a
04 10 2013 14:00:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	Warning		Application Sta
04 10 2013 13:45:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	OK	n/a	n/a
04 10 2013 13:45:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	OK		Application Sta
04 10 2013 13:40:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	Warning	n/a	n/a
04 10 2013 13:40:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	Warning		Application Sta
04 10 2013 13:25:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	OK	n/a	n/a
04 10 2013 13:25:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	OK		Application Sta
04 10 2013 13:20:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	Warning	n/a	n/a
04 10 2013 13:20:00	inst1[targethost1@pfmhost1]<RM Platform>	target1	Warning		Application Sta
04 10 2013 11:36:00	pfmhost1<Windows>	pfmhost1	Warning	n/a	n/a
04 10 2013 11:36:00	pfmhost1<Windows>	pfmhost1	Warning		Application Sta
04 10 2013 11:35:00	WIN- WT2AFYJYZEV<Windows>	WIN- WT2AFYJYZEV	Host Not Available	n/a	n/a
04 10 2013 11:35:00	WIN- WT2AFYJYZEV<HealthCheck>	WIN- WT2AFYJYZEV	Host Not Available	n/a	n/a
04 10 2013 11:35:00	pfmhost3<UNIX>	pfmhost3	Host Not Available	n/a	n/a
04 10 2013 11:34:49	inst1[All@pfmhost1]<RM Platform>	pfmhost1	OK	n/a	n/a
04 10 2013 11:34:49	inst1[targethost1@pfmhost1]<RM Platform>	target1	OK	n/a	n/a
04 10 2013 11:34:49	inst1[pfmhost1]<RM Platform>	pfmhost1	OK	n/a	n/a
04 10 2013 11:34:44	pfmhost1<Windows>	pfmhost1	OK	n/a	n/a
04 10 2013 11:34:38	pfmhost1<HealthCheck>	pfmhost1	OK	n/a	n/a

2. Click the report icon of the alarm for which a warning has been issued.

An Application Status report appears.

The Application Status report window shows a table of application status data. The table has columns: Record Time, Polling Time, Target Host Time, Application Name, Application Status, and Application Exist. The data is filtered to show only records where the Application Status is ABNORMAL.

Record Time	Polling Time	Target Host Time	Application Name	Application Status	Application Exist
04 10 2013 14:01:29	2013-04-10T05:00:48Z	2013-04-10T13:58:44+09:00	application1	ABNORMAL	NORMAL
04 10 2013 14:01:29	2013-04-10T05:00:48Z	2013-04-10T13:58:44+09:00	application2	NORMAL	NORMAL
04 10 2013 14:01:29	2013-04-10T05:00:48Z	2013-04-10T13:58:44+09:00	application3	NORMAL	NORMAL
04 10 2013 14:01:29	2013-04-10T05:00:48Z	2013-04-10T13:58:44+09:00	application4	NORMAL	NORMAL
04 10 2013 14:01:29	2013-04-10T05:00:48Z	2013-04-10T13:58:44+09:00	application5	NORMAL	NORMAL

3. Look for the lines where **ABNORMAL** is shown for **Application Status** or **Application Exist** to identify the application for which a warning was issued.

4. Under **Application Name**, select the application for which a warning was issued.

Here, application1 is selected.

An Application Process Status report appears.

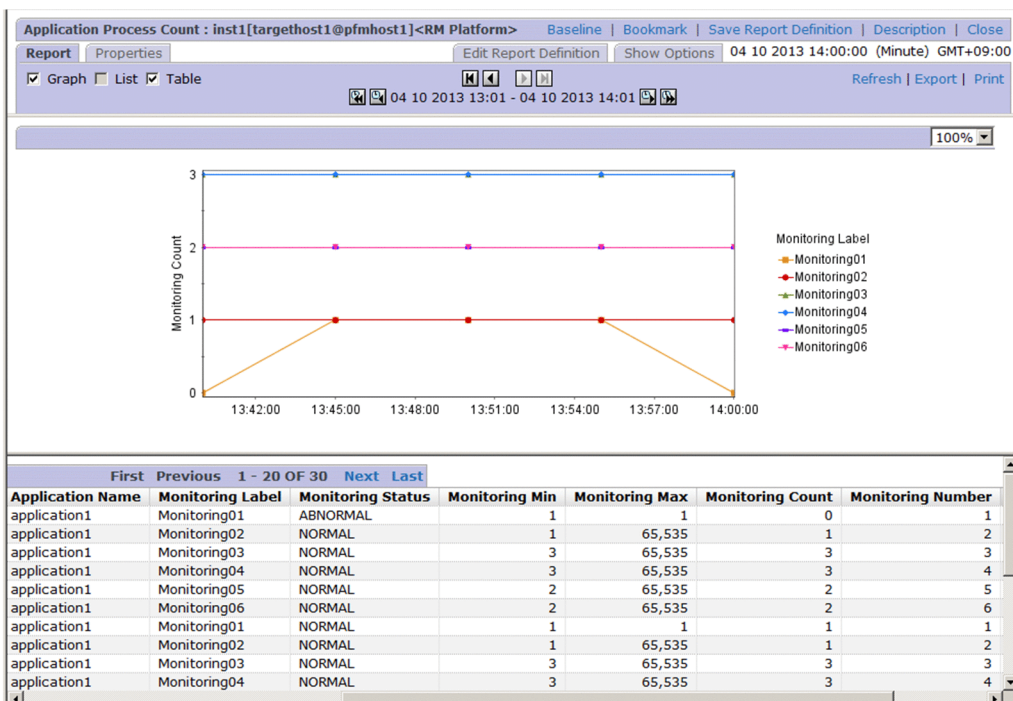

Application Process Status : inst1[targethost1@pfmhost1]<RM Platform>						
Bookmark Save Report Definition Description Close						
Report Properties Edit Report Definition Show Options 04 10 2013 14:01:26 (300s) GMT+09:00						
Graph List Table Refresh Stop						
OF 6 Next Last						
Monitoring Status	Monitoring Min	Monitoring Max	Monitoring Count	Monitoring Number	Monitoring Field	Monitoring Condition
ABNORMAL	1	1	0	1	Program Name	sample.exe
NORMAL	1	65,535	1	2	Program Name	System
NORMAL	3	65,535	3	3	Program Name	WmiPrvSE.exe
NORMAL	3	65,535	3	4	Program Name	csrss.exe
NORMAL	2	65,535	2	5	Program Name	dwm.exe
NORMAL	2	65,535	2	6	Program Name	explorer.exe
OF 6 Next Last						

5. Look for the lines where **ABNORMAL** is shown for **Monitoring Status** to identify the process for which a warning was issued.

Here, you can see that a warning was issued for `sample.exe`.

6. If you have collected the log data for the PD_APPC record, select a **Monitoring Count** value as needed.

An Application Process Count report appears. You can check the status of each process and whether the log related to the process count has increased or decreased.

Note:

If the alarm status is cancelled while a real-time report is being displayed, you cannot use the report to identify the process or service for which a warning was issued. An example of a real-time report is an Application Status report displayed by the event monitor, or an Application Process Status report displayed from an Application Status report. In this case, view the event monitor or an Application Process Count report (log report) to check the status transition that has occurred since the alarm was issued.

5

Operation in a Cluster System

This chapter describes the installation and setup of PFM - RM for Platform in a cluster system and the operating procedures when PFM - RM for Platform is run in a cluster system.

5.1 Configuration of PFM - RM for Platform in a cluster system

This section describes the configuration in which PFM - RM for Platform is run in a cluster system. For an overview of cluster systems and details about the system configuration for running the Performance Management system in a cluster system, see the chapter that describes system construction and operations in a cluster system in the *JP1/Performance Management User's Guide*.

If you run PFM - RM for Platform in a cluster system, you can improve availability because the system operation can be maintained by failover in the event of a problem.

To run PFM - RM for Platform in a cluster system, you must configure an environment in which the same instance of PFM - RM for Platform can be run in both the executing node and the standby node. Also you must store all data, such as data files, configuration files, and log files, on a shared disk.

When PFM - RM for Platform is run in a cluster system, it is configured as shown below.

Figure 5–1: Example of the configuration of PFM - RM for Platform in a cluster system (when PFM - RM for Platform is installed on the PFM - Manager host)

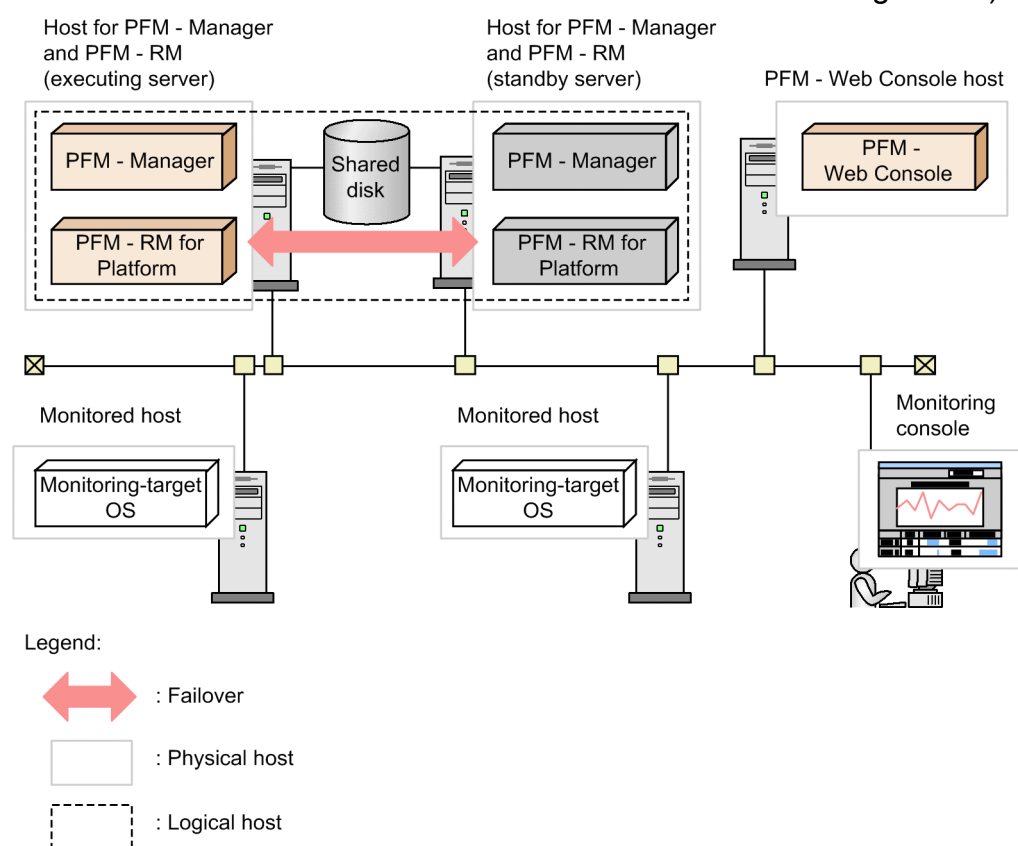

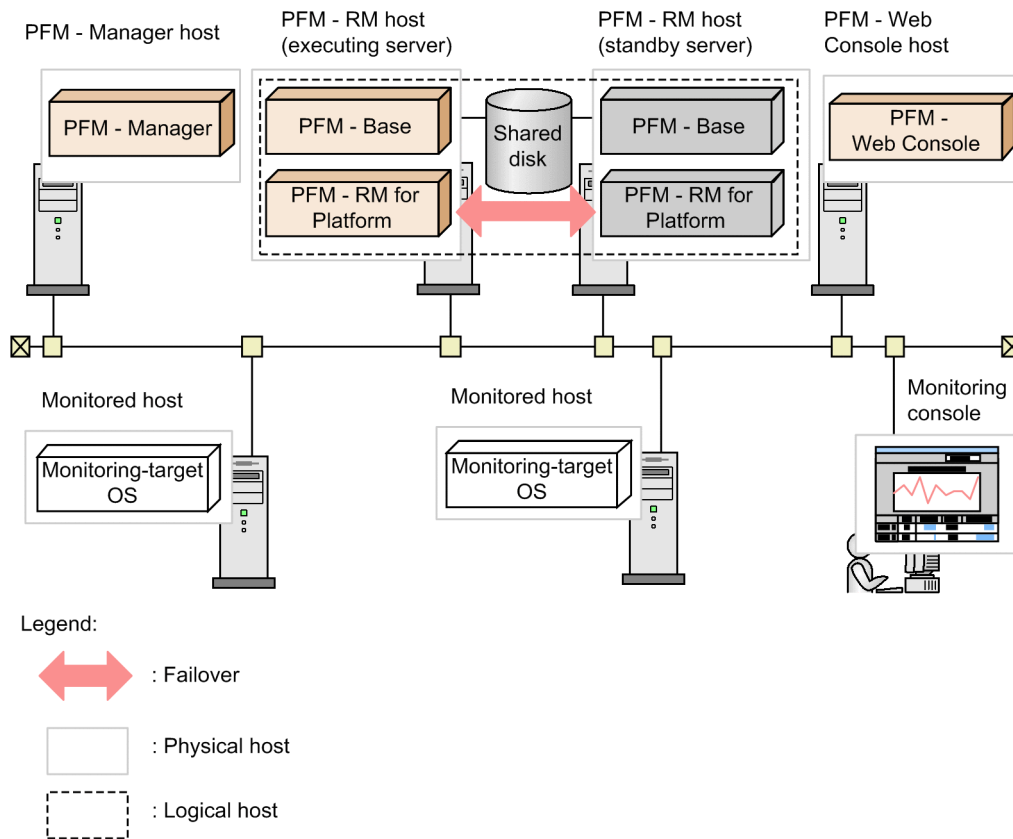

Figure 5–2: Example of the configuration of PFM - RM for Platform in a cluster system (when PFM - RM for Platform is installed on a different host from the PFM - Manager host)

PFM - RM for Platform in a cluster system runs in a logical host environment and monitors other hosts as monitoring targets. Therefore, you must configure the system in such a manner that the same host names can be used to connect to the monitored hosts from each host.

PFM - RM for Platform stores necessary information on the shared disk, such as definition and performance information, and inherits this information in the event of a failover. If a single logical host contains multiple Performance Management programs, all of them use the same shared directory.

You can run multiple PFM - RM for Platforms at the same node. If there are multiple cluster configurations (active-active configuration), run PFM - RM for Platform in each logical host environment. You can operate each PFM - RM for Platform independently and have them perform failover separately.

5.2 Processing when a failover occurs

If a failure occurs on the executing node, control shifts to the standby node.

This section describes the failover processing when a failure occurs in PFM - RM for Platform. It also describes the effects of a PFM - Manager failure on PFM - RM for Platform.

5.2.1 Failover when an error occurs at the PFM - RM host

The following figure shows the processing when failover occurs at the host PFM - RM host.

Figure 5–3: Processing when failover occurs at the PFM - RM host (when PFM - RM for Platform is installed on the PFM - Manager host)

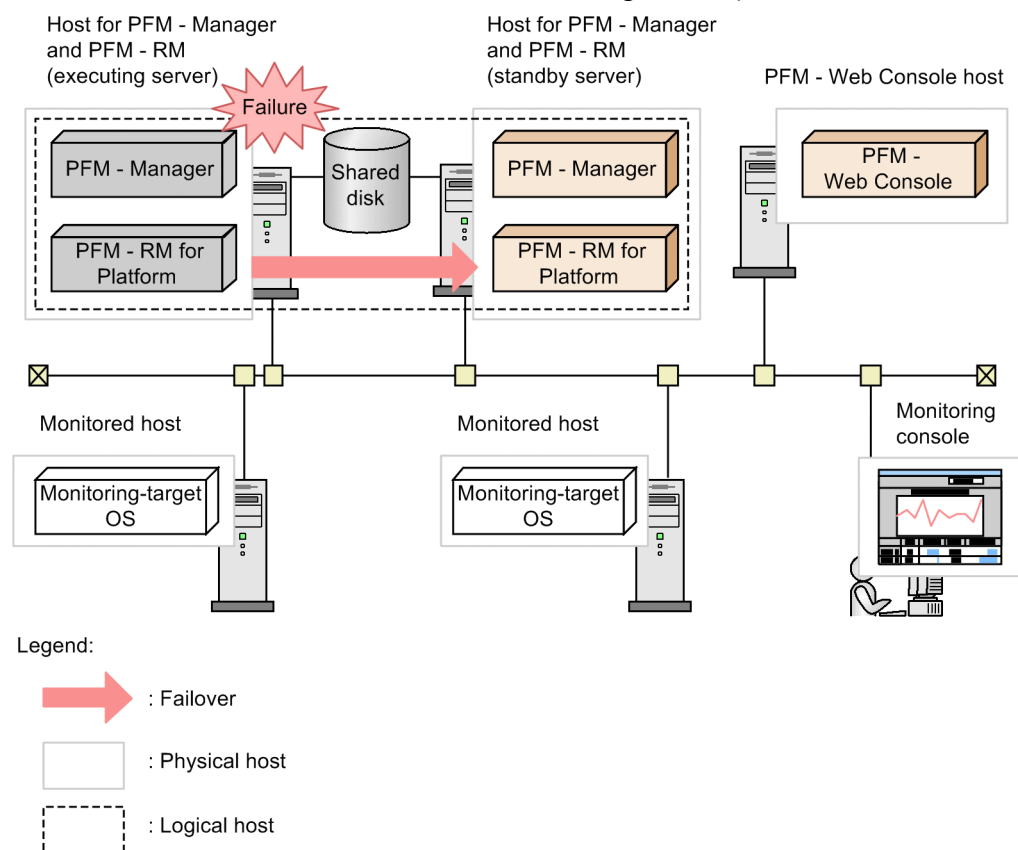

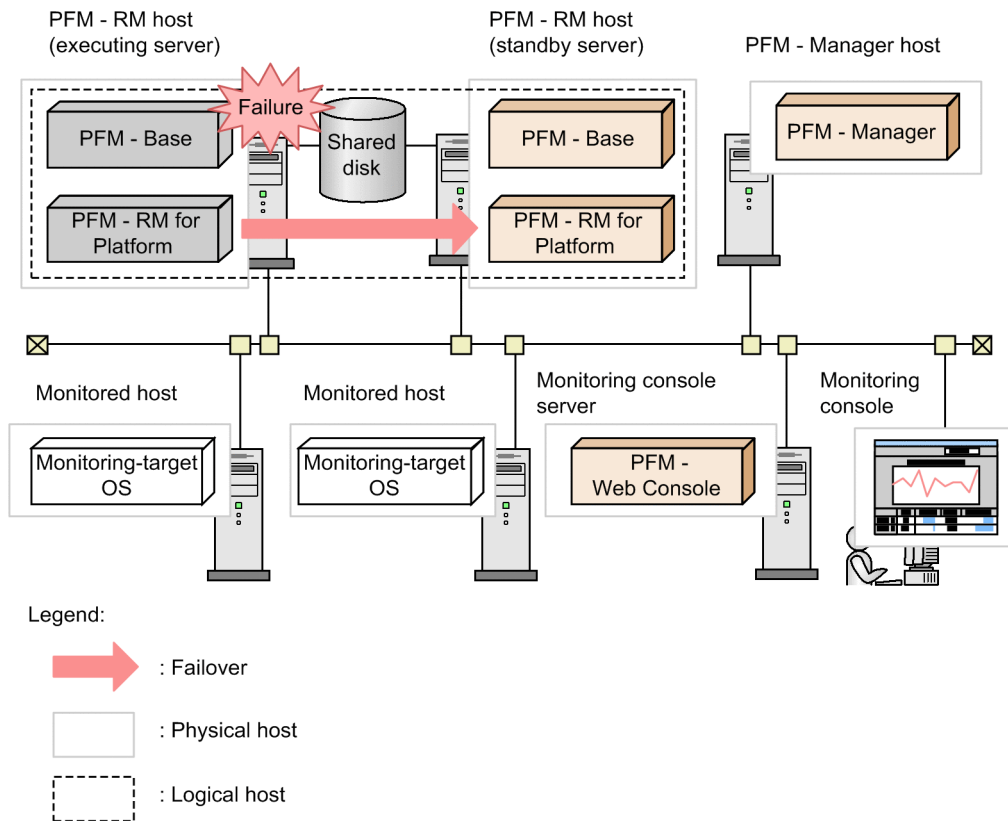

Figure 5–4: Processing when failover occurs at the PFM - RM host (when PFM - RM for Platform is installed on a different host from the PFM - Manager host)

If PFM - Web Console is used while PFM - RM for Platform is engaged in failover processing, the message `There was no answer (-6)` is displayed. If this message is displayed, wait until failover processing is completed.

Once failover is completed at PFM - RM for Platform, an attempt to use PFM - Web Console connects you to the PFM - RM for Platform that has started at the target node, so that you can perform operations.

5.2.2 Effects of PFM - Manager shutdown and the action to take

A shutdown of PFM - Manager has effects on the entire Performance Management system.

PFM - Manager provides centralized management of the agent information for PFM - RM for Platform that is running at each node. It also controls alarm event notifications when thresholds are exceeded during performance monitoring by PFM - RM for Platform as well as execution of actions based on alarm events.

The following describes the effects of a PFM - Manager shutdown on PFM - RM for Platform.

Effects

If PFM - Manager shuts down while PFM - RM for Platform is running, the effects described below result. Note that collection of performance data continues.

- Because alarm events cannot be reported to PFM - Manager, alarm events are retained for each alarm definition. PFM - RM for Platform retries notification until PFM - Manager starts. When the number of retained alarm events exceeds 3, the oldest alarm event is overwritten. If PFM - RM for Platform is shut down, the retained alarm events are deleted.

- Any notification of alarm status already sent to PFM - Manager is reset when PFM - Manager restarts. The alarm status is refreshed after PFM - Manager has checked the status of PFM - RM for Platform.
- Shutting down PFM - RM for Platform takes a while because no notification of this event can be sent to PFM - Manager.

Action

Start PFM - Manager. An active PFM - RM for Platform can continue its operation. However, alarms might not be notified as expected.

After PFM - Manager has been recovered, check the common message log for the KAVE00024-I message.

Evaluate the operation method, taking into account the effects of PFM - Manager shutdown. In addition to problems, events such as configuration change and maintenance might require shutdown of PFM - Manager. We recommend that you ensure that shutdowns for maintenance purposes be performed only when the shutdown will have the least adverse effects on operations.

5.3 Installation and setup in a cluster system (for Windows)

This section describes the procedures for installing and setting up PFM - RM for Platform in a cluster system.

For details about how to install and set up PFM - Manager, see the chapter that describes configuration and operation of cluster systems in the *JP1/Performance Management User's Guide*.

5.3.1 Items to be checked before installing in a cluster system (for Windows)

This subsection describes items to be checked before you start installation of PFM - RM for Platform.

(1) Prerequisites

Following are the prerequisites for using PFM - RM for Platform in a cluster system.

(a) Cluster system

Make sure that the following conditions are satisfied:

- The cluster system is controlled by cluster software.
- The cluster software is set up in such a manner that it controls startup and termination of the PFM - RM for Platform that is running on the logical host.
- Both the executing node and the standby node are set up to disable error reporting to Microsoft.

In Windows, if an application error occurs, a dialog box will be displayed to report the error to Microsoft. If this dialog box is displayed, a failover could not occur. Therefore, you must disable error reporting. If the nodes have not been set up to disable error reporting, take the following steps.

In Windows Server 2008

1. Choose **Control Panel > System and Security > Action Center > Maintenance**.
2. In **Check for solutions to problem reports**, click **Settings**.
3. In the Choose when to check for solutions to problem reports dialog box, choose **Never check for solutions (not recommended)**.
4. Click the **OK** button.

In Windows Server 2012

1. Choose **Control Panel > System and Security > Action Center > Maintenance**.
2. In **Check for solutions to unreported problems**, click **Settings**.
3. In the **Windows Error Reporting Configuration** dialog box, choose **I don't want to participate, and don't ask me again**.
4. Click the **OK** button.

In Windows Server 2016

1. Right-click the Windows **Start** menu and then choose **Run** from the displayed menu.
2. Enter `gpedit.msc`, and then click the **OK** button.

The Local Group Policy Editor appears.

3. Click **Computer Configuration, Administrative Templates, Windows Components**, and then **Windows Error Reporting**.
4. In the right pane, right-click **Disable Windows Error Reporting**, and then from the displayed menu, choose **Edit**.
The setting window appears.
5. In the setting window, select the **Enabled** check box.
6. Click the **OK** button.

(b) Shared disk

Make sure that the following conditions are satisfied:

- A shared disk is available to each logical host and information can be inherited from the executing node to the standby node.
- The shared disk is connected to each node physically by Fibre Channel or SCSI.^{#1}
- The shared disk can be placed offline forcibly by means such as the cluster software in order to implement failover even when there is still an active process that is using the shared disk.
- If multiple PFM products are running on the same logical host, the shared disk uses the same directory names.^{#2}

#1

Performance Management does not support a configuration that uses a network drive or a disk replicated via the network as the shared disk.

#2

You can change the storage location of the Store database and store it in a different folder on the shared disk.

(c) Logical host names and logical IP addresses

Make sure that the following conditions are satisfied:

- Each logical host has a logical host name and a corresponding logical IP address, and that this information can be inherited from the executing node to the standby node.
- The logical host names and logical IP addresses are set in the `hosts` file and name server.
- If DNS operation is employed, the host name without the domain name is used as the logical host name, not the FQDN name.
- All physical and logical host names are unique within the system.

Important

- Do not specify a physical host name (host name displayed by the `hostname` command) as a logical host name. If you do so, normal communication processing might not occur.
- A logical host name is expressed using from 1 to 32 bytes of alphanumeric characters. None of the following symbols nor the space character can be used:
/ \ : ; * ? ' " < > | & = , .
- For a logical host name, you cannot specify `localhost`, an IP address, or a host name beginning with a hyphen (-).

(d) Settings for using IPv6

Performance Management supports both IPv4 and IPv6 network environments. Therefore, you can run Performance Management even in a network environment where IPv4 and IPv6 coexist.

PFM - RM for Platform can use IPv6 to communicate with PFM - Manager. However, this applies only when the OS of the hosts on which PFM - RM for Platform and PFM - Manager are installed are Windows or Linux. For details about the applicable scope of communication in the IPv4 and IPv6 environments, see [L. Communication in IPv4 and IPv6 Environments](#).

To communicate in IPv6, you must enable the use of IPv6 on both the PFM - Manager host and the PFM - RM host. You specify this setting by executing the `jpcconf ipv6 enable` command. The following explains the conditions to use for determining whether you need to execute this command.

Cases in which you need to execute the `jpcconf ipv6 enable` command:

- When all hosts are being changed from an IPv4 environment to an IPv6 environment
- In an environment where IPv4 and IPv6 coexist and PFM - Manager is being changed from an IPv4 environment to an IPv6 environment

Cases in which you do not need to execute the `jpcconf ipv6 enable` command:

- When all hosts are already in an IPv6 environment
- In an environment where IPv4 and IPv6 coexist and PFM - Manager is already in an IPv6 environment

An example of executing the `jpcconf ipv6 enable` command follows:

```
jpcconf ipv6 enable
```

Execute the `jpcconf ipv6 enable` command separately on the executing node and on the standby node.

For details about the `jpcconf ipv6 enable` command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*. For details about the conditions and timing for executing the `jpcconf ipv6 enable` command, see the chapter that describes an example of a network configuration that includes an IPv6 environment in the *JPI/Performance Management Planning and Configuration Guide*.

When PFM - RM for Platform will use IPv6 to communicate with monitored hosts, specify a monitored host name that can be resolved.

PFM - RM for Platform uses a resolvable IP address to communicate with a monitoring target. When PFM - RM for Platform communicates with a monitoring target in an environment where IPv4 and IPv6 coexist, PFM - RM for Platform will not try to communicate using another IP address if communication using a resolvable IP address fails.

For example, if a connection attempt using IPv4 fails, PFM - RM for Platform will not retry using IPv6. Conversely, if a connection attempt using IPv6 fails, PFM - RM for Platform will not retry using IPv4. Therefore, make sure beforehand that connection can be established.

(e) WMI connection

Make sure that the following conditions are satisfied:

- The same user account that can connect to the monitored hosts by using WMI is available in the environments for both the executing node and the standby node.

For details about the WMI connection settings, see [3.1.5 WMI connection setting method \(when both the PFM - RM host and the monitored host are running Windows\)](#).

(f) SSH connection

Make sure that the following conditions are satisfied:

- A private key using the same path is available in the environments for both the executing node and the standby node.
- That private key can be used to connect to the monitored hosts.
- PuTTY is installed on the same path in the environments for both the executing node and the standby node.
- ActivePerl is installed on the same path in the environments for both the executing node and the standby node.

Note:

Use one of the following methods to register the private and public keys:

- Copy the private key created on the executing server to the standby server, and then establish its correspondence with the public key that is distributed from the executing server to the monitored host.
- Create public keys on both the executing and standby servers, and then establish correspondence between them by registering both public keys on the monitored hosts.

For details about the SSH connection settings, see [3.1.6 SSH connection setting method for Windows \(when the PFM - RM host is running Windows and the monitored host is running UNIX\)](#).

(2) Information needed for setting up PFM - RM for Platform for logical host operation

If you run PFM - RM for Platform on a logical host, you need the information listed in the table below in addition to the environment information that is needed for setting up a normal PFM - RM for Platform.

Table 5–1: Information needed for setting up PFM - RM for Platform for logical host operation

No.	Item	Example
1	Logical host name	jpl-halrmp
2	Logical IP address	172.16.92.100
3	Shared disk	s:\jpl

If multiple Performance Management programs are running on the same logical host, all of them must use folders on the same shared disk.

For details about the space requirements on the shared disk, see [A. Estimating System Requirements](#).

(3) Notes about logical host failover

If you employ a system configuration in which PFM - RM for Platform runs on a logical host, evaluate whether the entire logical host should failover in the event of a PFM - RM for Platform failure.

If a PFM - RM for Platform failure is to result in failover of the entire logical host, any other job application that is running on the logical host will also result in failover, which might affect the job adversely.

Typically, we recommend that you use one of the following cluster software settings so that errors on PFM - RM for Platform do not affect the operation of other applications:

- Operation of PFM - RM for Platform is not monitored.
- Detection of PFM - RM for Platform errors does not result in failover.

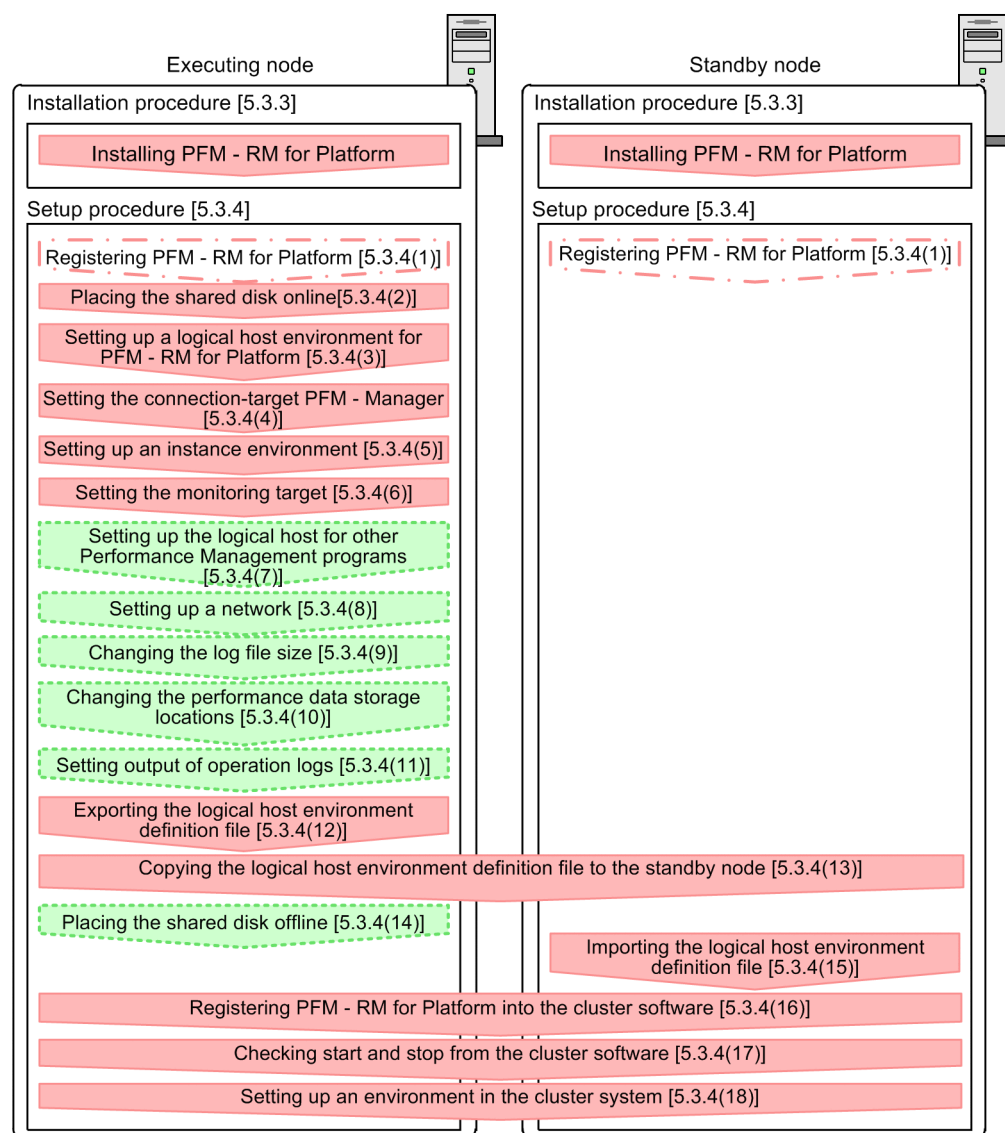

(4) Notes about upgrading when logical operation is used

To upgrade a PFM - RM for Platform that is running on a logical host, you must place the shared disk online at either the executing node or the standby node.

5.3.2 Flow of installation and setup in a cluster system (for Windows)

The following figure shows the procedures for installing and setting up PFM - RM for Platform in a cluster system.

Figure 5–5: Installation and setup procedures in a cluster system (for Windows)

Legend:

- : Required setup item
- : Optional setup item
- : Setup item that is required depending on the situation
- [] : Reference

Note:

Setting up PFM - RM for Platform in a logical host environment does not automatically inherit the existing PFM - RM Platform definition from the physical host environment. New environments are created when an instance environment is set up in the logical and physical host environments.

For setup commands that require a user input, you can select whether to execute the commands in the interactive or non-interactive mode.

When a command is executed in the interactive mode, the user must enter a value in response to the instruction from the command.

When a command is executed in the non-interactive mode, no user input is required because option specification or a definition file replaces the input step required during interactive command execution. Furthermore, batch processing or remote execution can automate the setup procedure, thereby reducing the workload on the administrator and the operating costs. Commands in the non-interactive mode are convenient in the following cases:

- You want to change the password used for connecting to monitoring targets on a regular basis.
- You want to improve the efficiency of the procedure for adding multiple monitoring targets.

For details about commands, see the manual *JPI/Performance Management Reference*.

5.3.3 Installation procedure in a cluster system (for Windows)

Install PFM - Base and PFM - RM for Platform on both the executing node and the standby node.

Important

The installation target is the local disk. Do not install PFM - RM for Platform on a shared disk.

The installation procedure is the same as for non-cluster systems. For details about the installation procedure, see [3.1.3 Installation procedure for the Windows edition](#).

5.3.4 Setup procedure in a cluster system (for Windows)

This subsection describes the setup needed for running Performance Management in a cluster system.

To run Performance Management in a cluster system, you must set up both the executing node and the standby node. Set up the executing node first, and then set up the standby node.

Executing system

indicates an item that is to be executed at the executing node, and

Standby system

indicates an item that is to be executed at the standby node.

Optional

indicates the following setup items:

- Setup item that is required depending on the environment in use
- Setup item for changing the default settings

Important

Do not set `JPC_HOSTNAME` as an environment variable because it is used by Performance Management. If it is set as an environment variable by mistake, Performance Management will not function correctly.

(1) Registering PFM - RM for Platform

Executing system

Standby system

Optional

To achieve central management of PFM - RM for Platform in the Performance Management system, you must register PFM - RM for Platform into PFM - Manager and PFM - Web Console.

You must register PFM - RM for Platform at the following times:

- When you add a new PFM - RM for Platform in the Performance Management system.
- When you update the Data model version for the registered PFM - RM for Platform.

You use PFM - Manager and PFM - Web Console to register PFM - RM for Platform. The registration procedure is the same as when a cluster system is not used. For details about the procedure, see [3.1.4\(1\) Registering PFM - RM for Platform](#).

(2) Placing the shared disk online

Executing system

Make sure that the shared disk is online.

If the shared disk is not in online status, use a program such as the cluster software or a volume manager to place it online.

(3) Setting up a logical host environment for PFM - RM for Platform

Executing system

Execute the `jpccnf ha setup` command to create a logical host environment.

This command creates a logical host environment by copying necessary data to the shared disk and setting definitions for a logical host.

Note

Before you execute the command, stop all Performance Management programs and services in the entire Performance Management system. For details about how to stop services, see the chapter that describes startup and termination of Performance Management in the *JP1/Performance Management User's Guide*.

To set up a logical host environment for PFM - RM for Platform:

1. Execute the `jpccnf ha setup` command to create a logical host environment for PFM - RM for Platform.

Execute the following command:

```
jpccnf ha setup -key RMPlatform -lhost jp1-halrmp -d S:\jp1
```

Use the `-lhost` option to specify the logical host name. This example specifies `jp1-halrmp` as the logical host name. If you employ DNS operations, specify the logical host name without the domain name.

Specify in the `-d` option a folder name on the shared disk within the environment folder. For example, if `-d S:\jp1` is specified, `S:\jp1\jp1pc` is created, and then files for the logical host environment are created.

2. Execute the `jpccnf ha list` command to check the logical host settings.

Execute the following command:

```
jpccconf ha list -key all
```

Make sure that the created logical host environment is correct.

(4) Setting the connection-target PFM - Manager Executing system

Execute the `jpccconf mgrhost define` command to set the PFM - Manager that manages PFM - RM for Platform.

To set the connection-target PFM - Manager:

1. Execute the `jpccconf mgrhost define` command to set the connection-target PFM - Manager.

Execute the following command:

```
jpccconf mgrhost define -host jpl-hal -lhost jpl-halrmp
```

Specify in the `-host` option the host name of the connection-target PFM - Manager. If the connection-target PFM - Manager is to run on a logical host, specify in the `-host` option the logical host name of the connection-target PFM - Manager. This example specifies `jpl-hal` as the PFM - Manager's logical host name.

Use the `-lhost` option to specify the logical host name of PFM - RM for Platform. This example specifies `jpl-halrmp` as the logical host name of PFM - RM for Platform.

The example above shows execution in the interactive mode, but you can also execute the `jpccconf mgrhost define` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

(5) Setting up an instance environment Executing system

Execute the `jpccconf inst setup` command to set up an instance environment for PFM - RM for Platform.

The setup procedure is the same as when a cluster system is not employed. However, in the case of a cluster system, you must specify the logical host name in the `-lhost` option when you execute the `jpccconf inst setup` command.

The following shows how to specify the `jpccconf inst setup` command for a cluster system:

```
jpccconf inst setup -key RMPlatform -lhost logical-host-name -inst instance-name
```

The example above shows execution in the interactive mode, but you can also execute the `jpccconf inst setup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

For details about the settings and procedure, see [3.1.4\(2\) Setting up an instance environment](#).

(6) Setting the monitoring target Executing system

Execute the `jpccconf target setup` command to set information about the monitored host for PFM - RM for Platform.

The setting procedure is the same as when a cluster system is not employed.

However, in the case of a cluster system, you must specify the logical host name in the `-lhost` option when you execute the `jpccconf target setup` command.

The following shows how to specify the `jpccconf target setup` command for a cluster system:

```
jpccconf target setup -key RMPlatform -lhost logical-host-name -inst
instance-name -target monitoring-target-name
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf target setup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

For details about the settings and procedure, see [3.1.4\(3\) Setting the monitored host](#).

(7) Setting up the logical host for other Performance Management programs

If you have other PFM - Manager, PFM - Agent, or PFM - RM programs to be set up on the same logical host in addition to PFM - RM for Platform, set them up at this stage.

For details about the setup procedure, see the chapter that describes the configuration and operation of cluster systems in the *JPI/Performance Management User's Guide*.

(8) Setting up a network

You specify network settings if you need to change the network environment settings as appropriate to the network configuration where Performance Management is used.

The two network environment settings are described below. Change these settings if necessary.

- Setting IP addresses

Set this information to use Performance Management in a network that is connected to multiple LANs. To specify an IP address to be used, directly edit the contents of the `jpchosts` file.

Copy the edited `jpchosts` file from the executing node to the standby node under *physical-host-installation-folder* \jp1pc\.

For details about how to set IP addresses, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

- Setting port numbers

If you establish communication between Performance Management programs via a firewall, use the `jpccconf port define` command to set the port numbers.

For details about how to set port numbers, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide* and the chapter that describes configuration and operation of cluster systems in the *JPI/Performance Management User's Guide*.

(9) Changing the log file size

The operation status of Performance Management is output to a log file unique to Performance Management. This log file is called the *common message log*. The common message log consists of two files with a default size of 2,048 kilobytes each. If necessary, use this setting to change this file size.

For details, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

(10) Changing the performance data storage locations Executing system

Optional

This setting is used to change the storage locations, backup folder, export folder, or import folder for the performance data that is managed by PFM - RM for Platform.

For details about the setting method, see [3.6.1 Changing performance data storage locations](#).

(11) Action log output setting Executing system

Optional

This setting is required in order to output action logs in the event of an alarm.

An action log consists of log information about exceeded threshold values caused by factors such as system loading; its output is linked with the alarm function. For details about the setting method, see [1. Outputting Action Log Data](#).

(12) Exporting the logical host environment definition file Executing system

After you have created a logical host environment for PFM - RM for Platform, export the environment definition to a file.

This export process involves output of the definition information for the Performance Management program that has been set up on the logical host to a file in the batch mode. If you are setting up other Performance Management programs on the same logical host, export the environment definition after all the setup processes are completed.

To export the logical host environment definition:

1. Execute the `jpccconf ha export` command to export the logical host environment definition.

Output the definition information for the logical host environment that has been created so far to an export file. You can assign any name to the export file.

For example, to export the logical host environment definition to the `lhostexp.txt` file, execute the following command:

```
jpccconf ha export -f lhostexp.txt
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf ha export` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

(13) Copying the logical host environment definition file to the standby node Executing system Standby system

Copy from the executing node to the standby node the logical host environment definition file exported in [\(12\) Exporting the logical host environment definition file](#).

(14) Placing the shared disk offline Executing system

Optional

Use a program such as the cluster software or a volume manager to place the shared disk offline and finish the procedure.

If you will be using the shared disk after you complete this procedure, there is no need to place it offline.

(15) Importing the logical host environment definition file Standby system

Import to the standby node the export file that was copied from the executing node.

Use the `jpccnf ha import` command to specify settings for executing at the standby node the Performance Management program on the logical host that was created at the executing node. If multiple Performance Management programs have been set up on the same logical host, the settings for all the programs are imported in the batch mode.

When you execute this command, there is no need to keep the shared disk in online status.

To import the logical host environment definition file:

1. Execute the `jpccnf ha import` command to import the logical host environment definition.

Execute the following command:

```
jpccnf ha import -f lhostexp.txt
```

This example shows execution in the interactive mode, but you can also execute the `jpccnf ha import` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

This command changes settings in such a manner that the environment for the standby node becomes the same as for the export file. As a result, the setup for starting PFM - RM for Platform on the logical host is performed.

If a fixed port number has been set by the `jpccnf port define` command during the setup, it is also set in the same manner.

2. Execute the `jpccnf ha list` command to check the logical host settings.

Execute the following command:

```
jpccnf ha list -key all
```

Make sure that the displayed information is the same as when the `jpccnf ha list` command is executed at the executing node.

(16) Registering PFM - RM for Platform into the cluster software

Standby system

Executing system

To run a Performance Management program in a logical host environment, you must register the program into the cluster software and set up the environment in such a manner that the Performance Management program is started and terminated from the cluster software.

For details about how to register PFM - RM for Platform into the cluster software, see the cluster software documentation.

This subsection describes the settings for registering PFM - RM for Platform into the cluster software using an example of items that are registered into Windows WSFC.

For PFM - RM for Platform, register the services shown in the table below into the cluster software.

For dependency settings when PFM - RM for Platform coexists with PFM - Manager's logical host, see the chapter that describes planning and operation in the *JPI/Performance Management User's Guide*.

Table 5–2: PFM - RM for Platform services to be registered into the cluster software

No.	Name	Service name	Resource dependencies
1	PFM - RM Store for Platform <i>instance-name</i> [<i>LHOST</i>]	JP1PCAGT_7S_ <i>instance-name</i> [<i>LHOST</i>]	<ul style="list-style-type: none">• IP address resources• Physical disk resources
2	PFM - RM for Platform <i>instance-name</i> [<i>LHOST</i>]	JP1PCAGT_7A_ <i>instance-name</i> [<i>LHOST</i>]	<ul style="list-style-type: none">• Cluster resources in No. 1

No.	Name	Service name	Resource dependencies
3	PFM - Action Handler [LHOST]	JP1PCMGR_PH [LHOST]	<ul style="list-style-type: none"> • IP address resources • Physical disk resources

Replace [LHOST] with the logical host name. If the instance name is SDC1 and the logical host name is jp1-halrmp, then the name of the service is PFM - RM Store for Platform SDC1 [jp1-halrmp], and the service name is JP1PCAGT_7S_SDC1 [jp1-halrmp].

In the case of WSFC, register these services as WSFC resources. Set each resource as follows:

- In **Resource type**, register as **Generic Service**.
- Set **Resource Dependencies** as shown in [Table 5-2 PFM - RM for Platform services to be registered into the cluster software](#).
- Do not set **Startup parameters** or **Registry Replication**.
- In the **Policies** tab in the properties window, specify the settings according to whether you want a failover to occur in the event of a Performance Management program failure.
 - For example, if you want a failover to occur in the event of a PFM - RM for Platform failure, specify the following settings:
 - Select the **If resource fails, attempt restart on current node** radio button.
 - Select the **If restart is unsuccessful, fail over all resources in this service or application** check box[#].
 - As a guide, specify 3 for **Maximum restarts in the specified period**.

#

In Windows Server 2012 or later, this check box is **If restart is unsuccessful, fail over all resources in this Role**.

Note

A service registered in the cluster is started and stopped from the cluster. Therefore, set **Startup type** to **Manual** so that the service will not be started automatically during OS startup. Immediately after the setup is performed by the `jpccnf ha` setup command, the service is set to **Manual**.

Make sure that you do not use the following command to forcibly stop services:

```
jpccsp stop -key all -lhost logical-host-name -kill immediate
```

(17) Checking start and stop from the cluster software

Executing system

Standby system

Make sure that the Performance Management programs function normally by starting and terminating the programs from the cluster software at each node.

(18) Setting up an environment in the cluster system

Executing system

Standby system

After you have finished setting up the Performance Management programs, set up an environment for them so that PFM - Web Console can be used to display the monitoring target's operation status as a report according to the operating procedures and can send notifications to the user in the event of problems at the monitoring target.

For details about how to set up an environment for the Performance Management programs, see the chapter that describes the configuration and operation of cluster systems in the *JP1/Performance Management User's Guide*.

5.3.5 WMI connection setting method (when both the PFM - RM host and the monitored host are running Windows) in a cluster system

For details about the WMI connection setting method, see *3.1.1(5) Environment settings required for collecting performance data (when both the PFM - RM host and the monitored hosts are running Windows)* and *3.1.5 WMI connection setting method (when both the PFM - RM host and the monitored host are running Windows)*.

5.3.6 SSH connection setting method in a cluster system (when the PFM - RM host is running Windows and the monitored host is running UNIX) (for Windows)

For details about the SSH connection setting method, see *3.1.1(6) Environment settings required for collecting performance data (when the PFM - RM host is running Windows and the monitored hosts are running UNIX)* and *3.1.6 SSH connection setting method for Windows (when the PFM - RM host is running Windows and the monitored host is running UNIX)*.

5.4 Installation and setup in a cluster system (for UNIX)

This section describes the procedures for installing and setting up PFM - RM for Platform in a cluster system.

For details about how to install and set up PFM - Manager, see the chapter that describes configuration and operation of cluster systems in the *JPI/Performance Management User's Guide*.

5.4.1 Items to be checked before installing in a cluster system (for UNIX)

This subsection describes items to be checked before you start installation of PFM - RM for Platform.

(1) Prerequisites

Following are the prerequisites for using PFM - RM for Platform in a cluster system.

(a) Cluster system

Make sure that the following conditions are satisfied:

- The cluster system is controlled by cluster software.
- The cluster software is set up in such a manner that it controls startup and termination of the PFM - RM for Platform that is running on the logical host.

(b) Shared disk

Make sure that the following conditions are satisfied:

- A shared disk is available to each logical host and information can be inherited from the executing node to the standby node.
- The shared disk is connected to each node physically by Fibre Channel or SCSI.^{#1}
- The shared disk can be placed offline forcibly by means such as the cluster software in order to implement failover even when there is still an active process that is using the shared disk.
- If multiple PFM products are running on the same logical host, the shared disk uses the same directory names.^{#2}

#1

Performance Management does not support a configuration that uses a network drive or a disk replicated via the network as the shared disk.

#2

You can change the storage location of the Store database and store it in a different directory on the shared disk.

(c) Logical host names and logical IP addresses

Make sure that the following conditions are satisfied:

- Each logical host has a logical host name and a corresponding logical IP address, and that this information can be inherited from the executing node to the standby node.
- The logical host names and logical IP addresses are set in the `hosts` file and name server.
- If DNS operation is employed, the host name without the domain name is used as the logical host name, not the FQDN name.

- All physical and logical host names are unique within the system.

Important

- Do not specify a physical host name (host name displayed by the `uname -n` command) as a logical host name. If you do so, normal communication processing might not occur.
- A logical host name is expressed as 1 to 32 bytes of alphanumeric characters. None of the following symbols nor the space character can be used:
`/ \ : ; * ? ' " < > | & = , .`
- For a logical host name, you cannot specify `localhost`, an IP address, or a host name beginning with a hyphen (-).

(d) Settings for using IPv6

Performance Management supports both IPv4 and IPv6 network environments. Therefore, you can run Performance Management even in a network environment where IPv4 and IPv6 coexist.

PFM - RM for Platform can use IPv6 to communicate with PFM - Manager. However, this applies only when the OS of the hosts on which PFM - RM for Platform and PFM - Manager are installed are Windows, or Linux. For details about the applicable scope of communication in the IPv4 and IPv6 environments, see [L. Communication in IPv4 and IPv6 Environments](#).

To communicate in IPv6, you must enable the use of IPv6 on both the PFM - Manager host and the PFM - RM host. You specify this setting by executing the `jpccconf ipv6 enable` command. The following explains the conditions to use for determining whether you need to execute this command.

Cases in which you need to execute the `jpccconf ipv6 enable` command:

- When all hosts are being changed from an IPv4 environment to an IPv6 environment
- In an environment where IPv4 and IPv6 coexist and PFM - Manager is being changed from an IPv4 environment to an IPv6 environment

Cases in which you do not need to execute the `jpccconf ipv6 enable` command:

- When all hosts are already in an IPv6 environment
- In an environment where IPv4 and IPv6 coexist and PFM - Manager is already in an IPv6 environment

An example of executing the `jpccconf ipv6 enable` command follows:

```
jpccconf ipv6 enable
```

Execute the `jpccconf ipv6 enable` command separately on the executing node and the standby node.

For details about the `jpccconf ipv6 enable` command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*. For details about the conditions and timing for executing the `jpccconf ipv6 enable` command, see the chapter that describes an example of a network configuration that includes an IPv6 environment in the *JP1/Performance Management Planning and Configuration Guide*.

When PFM - RM for Platform will use IPv6 to communicate with monitored hosts, specify a monitored host name that can be resolved.

PFM - RM for Platform uses a resolvable IP address to communicate with a monitoring target. When PFM - RM for Platform communicates with a monitoring target in an environment where IPv4 and IPv6 coexist, PFM - RM for Platform will not try to communicate using another IP address if communication using a resolvable IP address fails.

For example, if a connection attempt using IPv4 fails, PFM - RM for Platform will not retry using IPv6. Conversely, if a connection attempt using IPv6 fails, PFM - RM for Platform will not retry using IPv4. Therefore, make sure beforehand that connection can be established.

(e) SSH connection

Make sure that the following conditions are satisfied:

- A private key on the same path is available in the environments for both the executing node and the standby node.
- That private key can be used to connect to the monitored hosts.

Note:

If you use the private key that is automatically generated when PFM - RM for Platform is installed, use one of the following methods to register the private and public keys:

- Copy the private key created at the executing server to the standby server, and then establish its correspondence with the public key that is distributed from the executing server to the monitored host.
- Create public keys at both executing and standby servers, and then establish correspondence between them by registering both public keys at the monitored hosts.

For details about the SSH connection settings, see [3.2.5 SSH \(for UNIX\) connection setting method](#).

(2) Information needed for setting up PFM - RM for Platform for logical host operation

If you run PFM - RM for Platform on a logical host, you need the information listed in the table below in addition to the environment information that is needed for setting up a normal PFM - RM for Platform.

Table 5–3: Information needed for setting up PFM - RM for Platform for logical host operation

No.	Item	Example
1	Logical host name	jp1-halrmp
2	Logical IP address	172.16.92.100
3	Shared disk	/jp1

If multiple Performance Management programs are running on the same logical host, all of them must use directories on the same shared disk

For details about the space requirements on the shared disk, see [A. Estimating System Requirements](#).

(3) Notes about logical host failover

If you employ a system configuration in which PFM - RM for Platform runs on a logical host, evaluate whether the entire logical host should failover in the event of a PFM - RM for Platform failure.

If a PFM - RM for Platform failure is to result in failover of the entire logical host, any other job application that is running on the logical host will also result in failover, which might affect the job adversely.

Typically, we recommend that you use one of the following cluster software settings so that errors on PFM - RM for Platform do not affect the operation of other applications:

- Operation of PFM - RM for Platform is not monitored.
- Detection of PFM - RM for Platform errors does not result in failover.

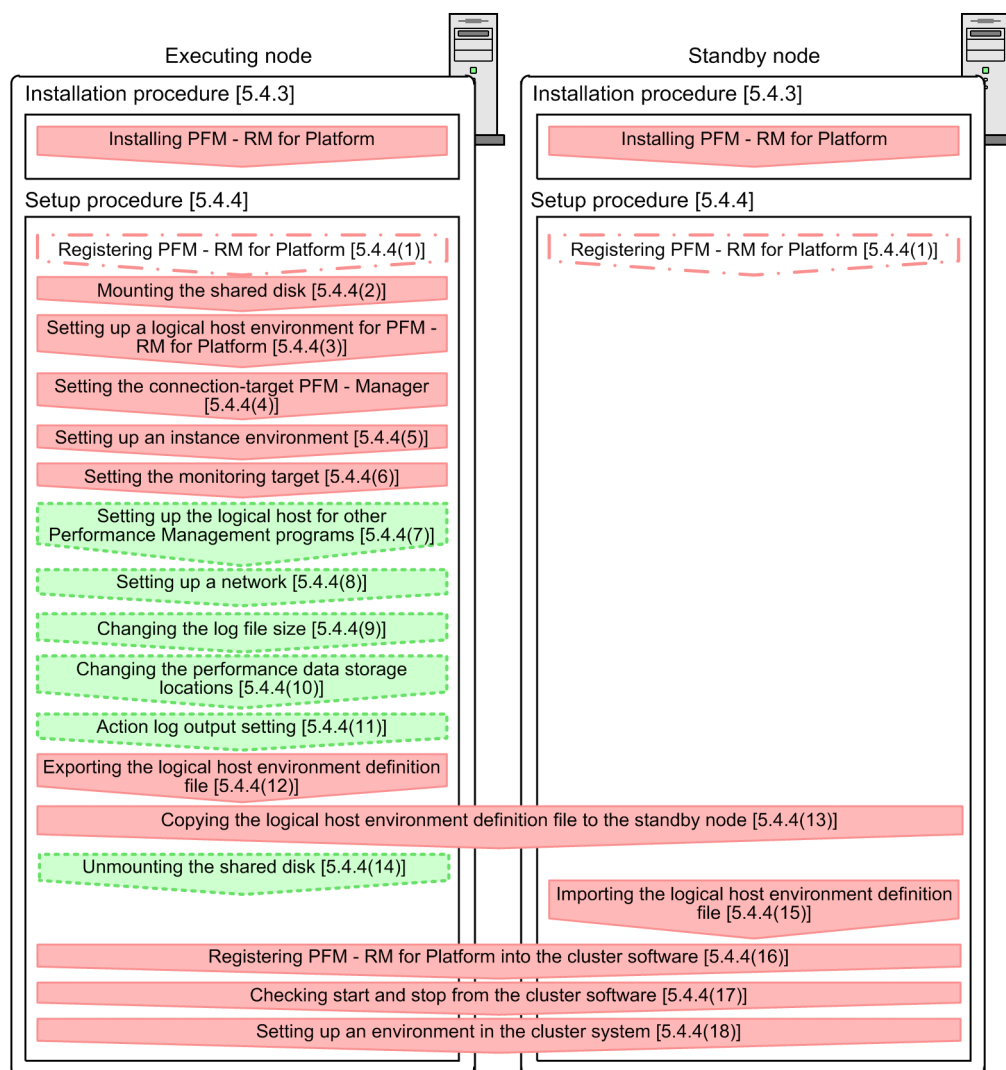

(4) Notes about upgrading when logical operation is used

To upgrade a PFM - RM for Platform that is running on a logical host, you must mount the shared disk at either the executing node or the standby node.

5.4.2 Flow of installation and setup in a cluster system (for UNIX)

The following figure shows the procedures for installing and setting up PFM - RM for Platform in a cluster system.

Figure 5–6: Installation and setup procedures in a cluster system (for UNIX)

Legend:

- : Required setup item
- : Setup item that is required depending on the situation
- : Optional setup item
- [] : Reference

Note:

Setting up a PFM - RM in a logical host environment does not inherit the existing PFM - RM definition in the physical host environment. A new environment is created when an instance environment is set up in the logical and physical host environments.

For setup commands that require a user input, you can select whether to execute the commands in the interactive or non-interactive mode.

When a command is executed in the interactive mode, the user must enter a value in response to the instruction from the command.

When a command is executed in the non-interactive mode, no user input is required because option specification or a definition file replaces the input step required during interactive command execution. Furthermore, batch processing or remote execution can automate the setup procedure, thereby reducing the workload on the administrator and the operating cost. Commands in the non-interactive mode are convenient in the following cases:

- You want to change the password used for connecting to monitoring targets on a regular basis.
- You want to improve the efficiency of the procedure for adding multiple monitoring targets.

For details about commands, see the manual *JP1/Performance Management Reference*.

5.4.3 Installation procedure in a cluster system (for UNIX)

Install PFM - Base and PFM - RM for Platform on both the executing node and the standby node.

The installation procedure is the same as for non-cluster systems. For details about the installation procedure, see [3.2.3 Installation procedure for the UNIX edition](#).

5.4.4 Setup procedure in a cluster system (for UNIX)

This subsection describes the setup needed for running Performance Management in a cluster system.

To run Performance Management in a cluster system, you must set up both the executing node and the standby node. Set up the executing node first, and then set up the standby node.

Executing system indicates an item that is to be executed at the executing node, and **Standby system** indicates an item that is to be executed at the standby node. **Optional** indicates the following setup items:

- Setup item that is required depending on the environment in use
- Setup item for changing the default settings

Important

Do not set `JPC_HOSTNAME` as an environment variable because it is used by Performance Management. If it is set as an environment variable by mistake, Performance Management will not function correctly.

(1) Registering PFM - RM for Platform **Executing system** **Standby system** **Optional**

To achieve central management of PFM - RM for Platform in the Performance Management system, you must register PFM - RM for Platform into PFM - Manager and PFM - Web Console.

You must register PFM - RM for Platform at the following times:

- When you add a new PFM - RM for Platform in the Performance Management system.
- When you update the Data model version for the registered PFM - RM for Platform.

You use PFM - Manager and PFM - Web Console to register PFM - RM for Platform. The registration procedure is the same as when a cluster system is not used. For details about the procedure, see [3.2.4\(2\) Registering PFM - RM for Platform](#).

(2) Mounting the shared disk **Executing system**

Make sure that the shared disk is mounted.

If the shared disk is not mounted, use a program such as the cluster software or a volume manager to mount it.

(3) Setting up a logical host environment for PFM - RM for Platform

Execute the `jpccconf ha setup` command to create a logical host environment. This command creates a logical host environment by copying necessary data to the shared disk and setting definitions for a logical host.

Note

Before you execute the command, stop all Performance Management programs and services in the entire Performance Management system. For details about how to stop services, see the chapter that describes the startup and termination of Performance Management in the *JPI/Performance Management User's Guide*.

To set up a logical host environment for PFM - RM for Platform:

1. Execute the `jpccconf ha setup` command to create a logical host environment for PFM - RM for Platform.

Execute the following command:

```
jpccconf ha setup -key RMPlatform -lhost jp1-halrmp -d /jp1
```

Use the `-lhost` option to specify the logical host name. This example specifies `jp1-halrmp` as the logical host name. If you employ DNS operations, specify the logical host name without the domain name.

Specify in the `-d` option a directory name on the shared disk within the environment directory. For example, if `-d /jp1` is specified, `/jp1/jp1pc` is created, and then files for the logical host environment are created.

2. Execute the `jpccconf ha list` command to check the logical host settings.

Execute the following command:

```
jpccconf ha list -key all
```

Make sure that the created logical host environment is correct.

(4) Setting the connection-target PFM - Manager

Execute the `jpccconf mgrhost define` command to set the PFM - Manager that manages PFM - RM for Platform.

To set the connection-target PFM - Manager:

1. Execute the `jpccconf mgrhost define` command to set the connection-target PFM - Manager.

Execute the following command:

```
jpccconf mgrhost define -host jp1-hal -lhost jp1-halrmp
```

Specify in the `-host` option the host name of the connection-target PFM - Manager. If the connection-target PFM - Manager is to run on a logical host, specify in the `-host` option the logical host name of the connection-target PFM - Manager. This example specifies `jp1-hal` as the PFM - Manager's logical host name.

Use the `-lhost` option to specify the logical host name of PFM - RM for Platform. This example specifies `jp1-halrmp` as the logical host name of PFM - RM for Platform.

The example above shows execution in the interactive mode, but you can also execute the `jpccconf mgrhost define` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

(5) Setting up an instance environment

Execute the `jpccconf inst setup` command to set up an instance environment for PFM - RM for Platform.

The setup procedure is the same as when a cluster system is not employed. However, in the case of a cluster system, you must specify the logical host name in the `-lhost` option when you execute the `jpccconf inst setup` command.

The following shows how to specify the `jpccconf inst setup` command for a cluster system:

```
jpccconf inst setup -key RMPlatform -lhost logical-host-name -inst instance-name
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf inst setup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

For details about the settings and procedure, see [3.2.4\(3\) Setting up an instance environment](#).

(6) Setting the monitoring target

Execute the `jpccconf target setup` command to set information about the monitored host for PFM - RM for Platform.

The setting procedure is the same as when a cluster system is not employed.

However, in the case of a cluster system, you must specify the logical host name in the `-lhost` option when you execute the `jpccconf target setup` command.

The following shows how to specify the `jpccconf target setup` command for a cluster system:

```
jpccconf target setup -key RMPlatform -lhost logical-host-name -inst instance-name -target monitoring-target-name
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf target setup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

For details about the settings and procedure, see [3.2.4\(4\) Setting the monitored host](#).

(7) Setting up the logical host for other Performance Management programs

If you have other PFM - Manager, PFM - Agent, or PFM - RM programs to be set up on the same logical host in addition to PFM - RM for Platform, set them up at this stage.

For details about the setup procedure, see the chapter that describes the configuration and operation of cluster systems in the *JP1/Performance Management User's Guide*.

(8) Setting up a network

You specify network settings if you need to change the network environment settings as appropriate to the network configuration where Performance Management is used.

The two network environment settings are described below. Change these settings if necessary.

- Setting IP addresses

Set this information to use Performance Management in a network that is connected to multiple LANs. To specify an IP address to be used, directly edit the contents of the `jpchosts` file.

Copy the edited `jpchosts` file from the executing node to the standby node under *physical-host-installation-directory*/`jp1pc`/.

For details about how to set IP addresses, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

- Setting port numbers

If you establish communication between Performance Management programs via a firewall, use the `jpccnf port define` command to set the port numbers.

For details about how to set port numbers, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide* and the chapter that describes configuration and operation of cluster systems in the *JPI/Performance Management User's Guide*.

(9) Changing the log file size Executing system Optional

The operation status of Performance Management is output to a log file unique to Performance Management. This log file is called the *common message log*. The common message log consists of two files with a default size of 2,048 kilobytes each. If necessary, use this setting to change this file size.

For details, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*.

(10) Changing the performance data storage locations Executing system Optional

This setting is used to change the storage locations, backup directory, export directory, or import directory for the performance data that is managed by PFM - RM for Platform

For details about the setting method, see [3.6.1 Changing performance data storage locations](#).

(11) Action log output setting Executing system Optional

This setting is required in order to output action logs in the event of an alarm.

An action log consists of log information about exceeded threshold values caused by factors such as system loading; its output is linked with the alarm function. For details about the setting method, see [1. Outputting Action Log Data](#).

(12) Exporting the logical host environment definition file Executing system

After you have created a logical host environment for PFM - RM for Platform, export the environment definition to a file.

This export process involves output of the definition information for the Performance Management program that has been set up on the logical host to a file in the batch mode. If you are setting up other Performance Management programs on the same logical host, export the environment definition after all the setup processes are completed.

To export the logical host environment definition:

1. Execute the `jpccnf ha export` command to export the logical host environment definition.

Output the definition information for the logical host environment that has been created so far to an export file. You can assign any name to the export file.

For example, to export the logical host environment definition to the `lhostexp.txt` file, execute the following command:

```
jpccnf ha export -f lhostexp.txt
```

This example shows execution in the interactive mode, but you can also execute the `jpccnf ha export` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

(13) Copying the logical host environment definition file to the standby node

Executing system

Standby system

Copy from the executing node to the standby node the logical host environment definition file exported in (12) *Exporting the logical host environment definition file*.

(14) Unmounting the shared disk

Executing system

Optional

Unmount the file system and finish the procedure.

If you will be using the shared disk after you complete this procedure, there is no need to unmount the file system.

Note

If the shared disk is unmounted but the specified environment directory contains the `jp1pc` directory and that directory has files under it, the setup is performed without unmounting the shared disk.

In such a case, perform the following procedure:

1. Use the `tar` command to archive the `jp1pc` directory that is located in the specified environment directory on the local disk.
2. Mount the shared disk.
3. If the specified environment directory does not exist on the shared disk, create an environment directory.
4. Expand the `tar` file in the environment directory on the shared disk.
5. Unmount the shared disk.
6. Delete all files and directories under the `jp1pc` directory that is located in the specified environment directory on the local disk.

(15) Importing the logical host environment definition file

Standby system

Import to the standby node the export file that was copied from the executing node.

Use the `jpccnf ha import` command to specify settings for executing at the standby node the Performance Management program on the logical host that was created at the executing node. If multiple Performance Management programs have been set up on the same logical host, the settings for all the programs are imported in the batch mode.

When you execute this command, there is no need to keep the shared disk mounted.

To import the logical host environment definition file:

1. Execute the `jpccnf ha import` command to import the logical host environment definition.
Execute the following command:

```
jpccnf ha import -f lhostexp.txt
```

This example shows execution in the interactive mode, but you can also execute the `jpccnf ha import` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

This command changes settings in such a manner that the environment for the standby node becomes the same as for the export file. As a result, the setup for starting PFM - RM for Platform on the logical host is performed.

If a fixed port number has been set by the `jpccnf port define` command during the setup, it is also set in the same manner.

2. Execute the `jpccnf ha list` command to check the logical host settings.

Execute the following command:

```
jpccnf ha list -key all
```

Make sure that the displayed information is the same as when the `jpccnf ha list` command is executed at the executing node

(16) Registering PFM - RM for Platform into the cluster software Executing system

Standby system

To run a Performance Management program in a logical host environment, you must register the program into the cluster software and set up the environment in such a manner that the Performance Management program is started and terminated from the cluster software.

For details about how to register PFM - RM for Platform into the cluster software, see the cluster software documentation.

This subsection describes the settings for registering PFM - RM for Platform into the cluster software.

When applications are registered into the UNIX cluster software, the following four items are typically required: *Start*, *Stop*, *Operation monitoring*, and *Forced stop*.

The following table shows how to set these items in PFM - RM for Platform.

Table 5–4: How to control a PFM - RM for Platform that is registered into the cluster software

No.	Item	Description
1	Start	<p>Execute the following commands in the order shown to start PFM - RM for Platform:</p> <ol style="list-style-type: none"> 1. <code>jpccspm start -key AH -lhost <i>logical-host-name</i></code> 2. <code>jpccspm start -key RMPlatform -lhost <i>logical-host-name</i> -inst <i>instance-name</i></code> <p>The time to do this is after the shared disk and logical IP address become available.</p>
2	Stop	<p>Execute the following commands in the order shown to terminate PFM - RM for Platform:</p> <ol style="list-style-type: none"> 1. <code>jpccspm stop -key RMPlatform -lhost <i>logical-host-name</i> -inst <i>instance-name</i></code> 2. <code>jpccspm stop -key AH -lhost <i>logical-host-name</i></code> <p>The time to do this is before the shared disk and logical IP address become unavailable.</p> <p>If the service has stopped for a reason such as a failure, the <code>jpccspm stop</code> command returns a value of 3. In such a case, the processing is treated as a normal termination because the service has stopped.</p> <p>If the cluster software uses the return value to determine the execution result, take appropriate action, such as setting the return value to 0.</p>
3	Operation monitoring	<p>Execute the <code>ps</code> command to check whether the indicated process is running:</p> <ul style="list-style-type: none"> • <code>ps -ef grep "<i>process-name logical-host-name</i>" grep -v "grep monitoring-target-process"</code>

No.	Item	Description
3	Operation monitoring	<p>The monitoring-target processes are as follows:</p> <ul style="list-style-type: none"> • <code>jpcagt7, agt7/jpcsto, jpcah</code> <p>For process names, see the chapter that describes planning and operation in a cluster system in the <i>JP1/Performance Management User's Guide</i>.</p> <p>Note that a process might have been stopped temporarily during Performance Management operation for a reason such as the need to perform system maintenance. To prepare for this, we recommend that you provide a method for suppressing operation monitoring (for example, monitoring is not to be performed when the system detects a file that indicates that system maintenance is underway).</p>
4	Forced stop	<p>If forced termination is necessary, execute the following command:</p> <ul style="list-style-type: none"> • <code>jpcspm stop -key all -lhost <i>logical-host-name</i> -kill immediate</code> <p>You can specify only <code>all</code> as the service key in the <code>-key</code> option.</p> <p>Note</p> <p>If you execute this command, all Performance Management processes in the specified logical host environment are terminated forcibly by <code>SIGKILL</code> transmission. In this case, the Performance Management processes are terminated forcibly in units of logical hosts, not services.</p> <p>Specify the settings so that forced termination is used only when processes cannot be terminated by normal termination.</p>

Notes:

- The Performance Management programs registered in the cluster are started and terminated by the cluster. Therefore, do not set automatic startup at the time of OS startup.
- If you execute Performance Management programs in a Japanese language environment, use the script registered in the cluster software to set up the `LANG` environment variable before executing Performance Management commands.
- If the cluster software uses the return value of a command to determine the execution result, specify the settings so that the return value of the Performance Management commands is converted to a value that can be handled by the cluster software. For details about the return values of Performance Management commands, see each command reference.
- The length of the text that can be displayed by the `ps` command depends on the OS. Set the text so that the total length of the logical host name and the instance name does not exceed 47 characters. If you want to use the `ps` command to monitor actions, execute the `ps` command in advance to make sure that the entire logical host name is displayed up to the end. Specify the settings so that if the displayed text is not complete, monitoring will apply based on the displayed characters. When you use the `ps` command to identify a specific process name and a logical host name, the command might fail to acquire a process name or a logical host name. If this occurs, the text might be displayed inside square brackets (`[]`). Check the reference for the `ps` command for your OS, and then re-execute the command.
- Start the monitored host first, and then start PFM - RM for Platform. During termination, terminate PFM - RM for Platform first, and then terminate the monitored host.

(17) Checking start and stop from the cluster software

Executing system

Standby system

Make sure that the Performance Management programs function normally by starting and terminating the programs from the cluster software at each node.

(18) Setting up an environment in the cluster system

Executing system

Standby system

After you have finished setting up the Performance Management programs, set up an environment for them so that PFM - Web Console can be used to display the monitoring target's operation status as a report according to the operating procedures and can send notifications to the user in the event of problems at the monitoring target.

For details about how to set up an environment for the Performance Management programs, see the chapter that describes the configuration and operation of cluster systems in the *JP1/Performance Management User's Guide*.

5.4.5 SSH connection setting method in a cluster system (for UNIX)

For details about how to set SSH connection, see [3.2.1\(5\) Environment settings required for collecting performance data \(for UNIX\)](#) and [3.2.5 SSH \(for UNIX\) connection setting method](#).

5.5 Uninstallation and unsetup in a cluster system (for Windows)

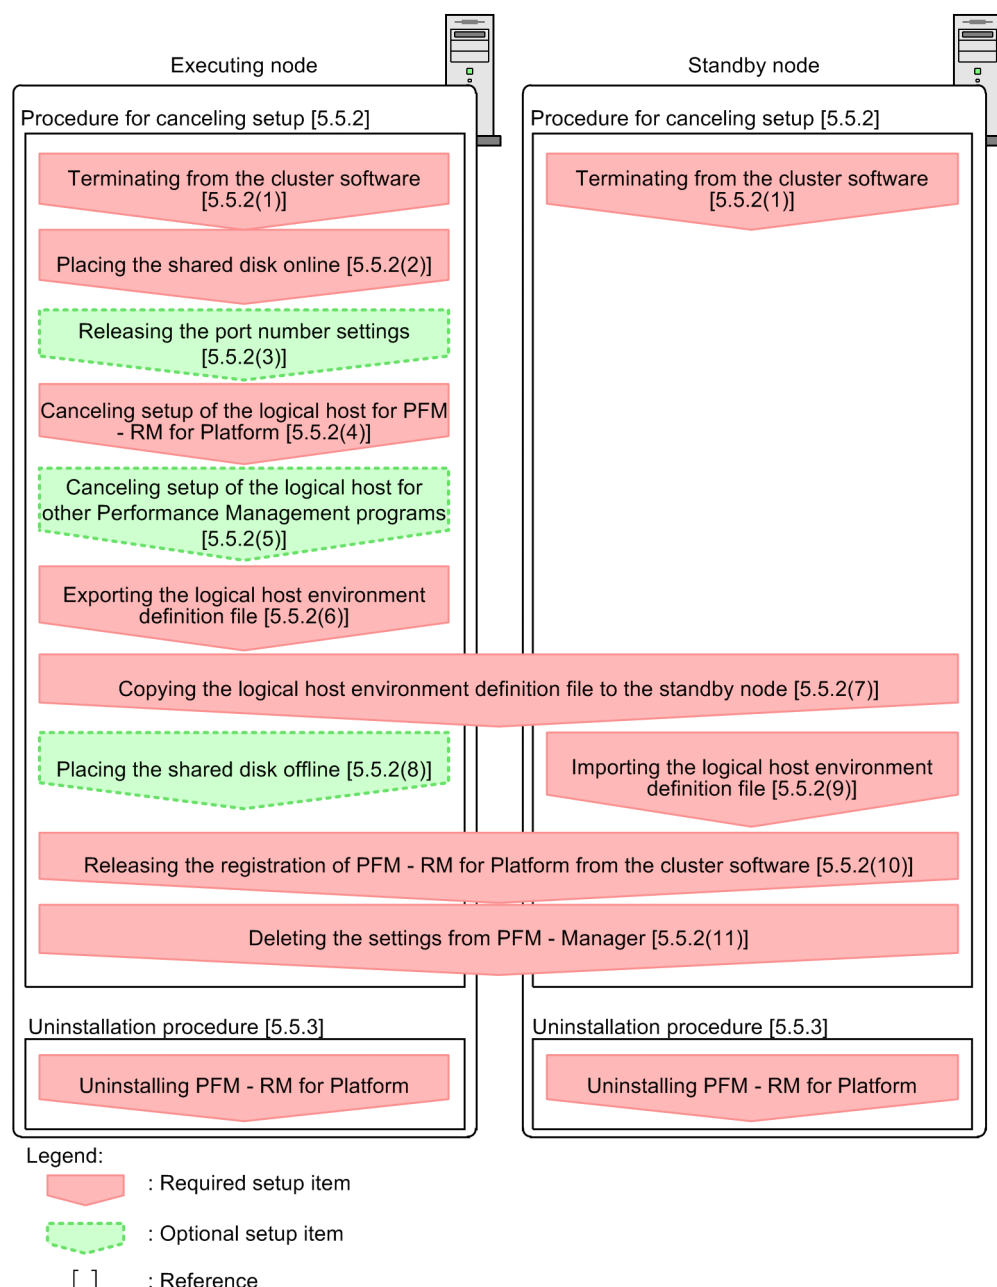

This section describes the procedures for uninstalling and canceling the setup of a PFM - RM for Platform that is running in a cluster system.

For details about uninstalling and canceling the setup of PFM - Manager, see the chapter that describes configuration and operation of cluster systems in the *JP1/Performance Management User's Guide*.

5.5.1 Flow of uninstallation and unsetup in a cluster system (for Windows)

The following figure shows the procedure for uninstalling and canceling the setup of a PFM - RM for Platform that is running in a cluster system.

Figure 5–7: Procedure for uninstalling and canceling the setup of a PFM - RM for Platform in a cluster system (for Windows)

5.5.2 Unsetup procedure in a cluster system (for Windows)

Cancel the setup of the logical host environment.

This procedure must be performed at both the executing node and the standby node. Cancel the setup at the executing node first, and then at the standby node.

Note that Executing system indicates the items to be executed at the executing node, Standby system indicates the items to be executed at the standby node, and Optional indicates the following setup items:

- Setup items that are required depending on the environment in use

- Setup items for changing the default settings

The following subsections describe how to cancel the setup of PFM - RM for Platform.

(1) Terminating from the cluster software Executing system Standby system

Use the cluster software to stop all the Performance Management programs and services running on the executing and standby nodes.

For details about how to stop programs and services, see the cluster software documentation.

(2) Placing the shared disk online Executing system

Make sure that the shared disk is online.

If the shared disk is not in online status, use a program such as the cluster software or a volume manager to place it online.

(3) Releasing the port number settings Executing system Optional

This procedure is required only when the `jpccconf port define` command was used to set port numbers during setup in an environment that uses a firewall.

For details about how to release port numbers, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide* and the chapter that describes configuration and operation of cluster systems in the *JPI/Performance Management User's Guide*.

(4) Canceling setup of the logical host for PFM - RM for Platform Executing system

This subsection describes how to cancel the setup of the logical host.

If a logical host environment is deleted while the shared disk is in offline status, the logical host settings are deleted from the physical host, but the folders and files are not deleted from the shared disk. In such a case, you must place the shared disk online and manually delete the `jp1pc` folder under the environment folder.

To cancel the setup of the logical host for PFM - RM for Platform:

1. Execute the `jpccconf ha list` command to check the logical host settings.

Execute the following command:

```
jpccconf ha list -key all-lhost logical-host-name
```

You must check the current settings before you cancel the setup of the logical host environment. Check such information as the name of the logical host and the path to the shared disk.

2. Execute the `jpccconf target unsetup` command to delete information about the monitoring host for PFM - RM for Platform.

Execute the following command:

```
jpccconf target unsetup -key RMPlatform -lhost logical-host-name -inst instance-name -target monitoring-target-name
```

The `jpccconf target unsetup` command excludes the specified monitored host on the logical host as a monitoring target.

3. Execute the `jpccconf inst unsetup` command to delete the instance environment for PFM - RM for Platform.

Execute the following command:

```
jpccconf inst unsetup -key RMPlatform -lhost logical-host-name -inst  
instance-name
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf inst unsetup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

The `jpccconf inst unsetup` command deletes the settings for starting the instance of the logical host. It also deletes files for the instance from the shared disk.

4. Execute the `jpccconf ha unsetup` command to delete the logical host environment for PFM - RM for Platform.

Execute the following command:

```
jpccconf ha unsetup -key RMPlatform -lhost logical-host-name
```

The `jpccconf ha unsetup` command deletes the settings for starting PFM - RM for Platform on the logical host. It also deletes files for the logical host from the shared disk.

5. Execute the `jpccconf ha list` command to check the logical host settings.

Execute the following command:

```
jpccconf ha list -key all
```

Make sure that PFM - RM for Platform has been deleted from the logical host environment.

(5) Canceling setup of the logical host for other Performance Management programs

If you are also canceling from the same logical host the setup of Performance Management programs other than PFM - RM for Platform, do so at this stage.

For details about the procedure for canceling the setup, see the chapter that describes configuration and operation of cluster systems in the *JPI/Performance Management User's Guide*. Also see the chapter that describes cluster system operation in each PFM - RM manual or PFM - Agent manual.

(6) Exporting the logical host environment definition file

After you have deleted the logical host environment for PFM - RM for Platform, export the environment definition to a file.

Performance Management achieves a matching environment in the executing and standby nodes by importing and exporting environment definitions. When the environment definition exported from the executing node (definition from which the Performance Management definition has been deleted) is imported to the standby node, the system compares it with the environment definition existing in the standby node (definition that still contains the Performance Management definition) to determine the differences (the portion deleted at the executing node), and then deletes the Performance Management environment definition.

To export the logical host environment definition file:

1. Execute the `jpccconf ha export` command to export the logical host environment definition.

Output the logical host environment definition information for Performance Management to an export file. You can assign any name to the export file. For example, to export the logical host environment definition to the `lhostexp.txt` file, execute the following command:

```
jpccconf ha export -f lhostexp.txt
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf ha export` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

(7) Copying the logical host environment definition file to the standby node

Executing system

Standby system

Copy from the executing node to the standby node the logical host environment definition file that was exported in (6) *Exporting the logical host environment definition file*.

(8) Placing the shared disk offline

Executing system

Optional

Use a program such as the cluster software or a volume manager to place the shared disk in offline status and finish the procedure.

If you will be using the shared disk after this procedure is completed, there is no need to place it in offline status.

(9) Importing the logical host environment definition file

Standby system

Import to the standby node the export file that was copied from the executing node. At the standby node, there is no need to place the shared disk in offline status during the import processing.

To import the logical host environment definition file:

1. Execute the `jpccconf ha import` command to import the logical host environment definition.

Execute the following command:

```
jpccconf ha import -f lhostexp.txt
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf ha import` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

This command changes settings in such a manner that the environment for the standby node becomes the same as for the export file. As a result, the settings for starting PFM - RM for Platform on the logical host are deleted. If you have canceled the setup of other Performance Management programs on the logical host, those settings are also deleted. If a fixed port number was set by the `jpccconf port define` command during the setup, it is also released.

2. Execute the `jpccconf ha list` command to check the logical host settings.

Execute the following command:

```
jpccconf ha list -key all
```

Make sure that the displayed information is the same as when the `jpccconf ha list` command is executed at the executing node.

(10) Releasing the registration of PFM - RM for Platform from the cluster software

Executing system

Standby system

From the cluster software, delete the settings related to PFM - RM for Platform on the logical host.

For details about how to delete the settings, see the cluster software documentation.

(11) Deleting the settings from PFM - Manager

Executing system

Standby system

From PFM - Web Console, log in to PFM - Manager and delete the settings related to the PFM - RM for Platform that you want to unsetup.

To delete the settings from PFM - Manager:

1. Start the PFM - Manager service.

If the PFM - Manager service was stopped in [5.5.2\(1\) Terminating from the cluster software](#), use the cluster software to start the PFM - Manager service. For details about how to start the service, see the cluster software manual.

2. From PFM - Web Console, delete the agent.

3. Delete the agent information from PFM - Manager.

For example, if PFM - Manager is running on logical host `jp1-hal` and PFM - RM for Platform is running on logical host `jp1-halrmp`, execute the following command:

```
jpccconf ha list -key all\tools\jpctool service delete -id service-ID -  
host jp1-halrmp -lhost jp1-hal
```

In *service-ID*, specify the service ID of the agent that is to be deleted.

4. Restart the PFM - Manager service.

For details about how to start services, see the chapter that describes startup and termination of Performance Management in the *JP1/Performance Management User's Guide*.

5. Apply the service information of PFM - Manager host.

To apply the deletion of the service information to the PFM - Web Console host, synchronize the agent information between the PFM - Manager host and the PFM - Web Console host. To synchronize the agent information, use the `jpctool service sync` command.

5.5.3 Uninstallation procedure in a cluster system (for Windows)

Uninstall PFM - RM for Platform from both the executing node and the standby node.

The uninstallation procedure is the same as when a cluster system is not employed. For details about the procedure, see [3.3.3 Procedure for uninstalling the Windows edition](#).

Notes

- Before you uninstall PFM - RM for Platform, stop all Performance Management programs and services at the node where PFM - RM for Platform is to be uninstalled.
- If you uninstall PFM - RM for Platform without deleting the logical host environment, the environment folders might remain. In such a case, manually delete the environment folders.

5.6 Uninstallation and unsetup in a cluster system (for UNIX)

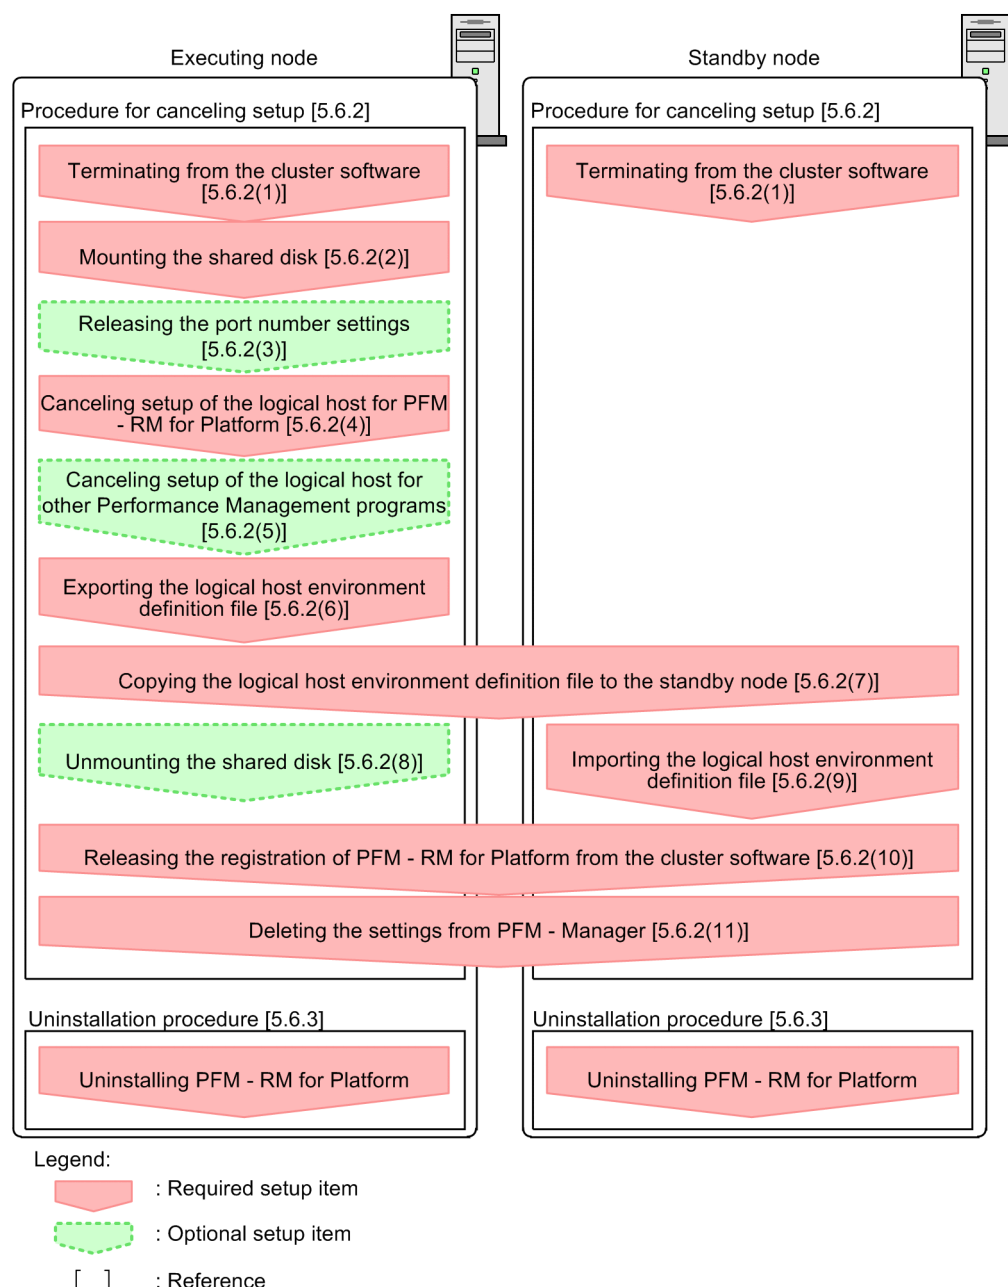

This section describes the procedures for uninstalling and canceling the setup of a PFM - RM for Platform that is running in a cluster system.

For details about uninstalling and canceling the setup of PFM - Manager, see the chapter that describes configuration and operation of cluster systems in the *JP1/Performance Management User's Guide*.

5.6.1 Flow of uninstallation and unsetup in a cluster system (for UNIX)

The following figure shows the procedure for uninstalling and canceling the setup of a PFM - RM for Platform that is running in a cluster system.

Figure 5–8: Procedure for uninstalling and canceling the setup of a PFM - RM for Platform in a cluster system (for UNIX)

5.6.2 Unsetup procedure in a cluster system (for UNIX)

Cancel the setup of the logical host environment.

This procedure must be performed at both the executing node and the standby node. Cancel the setup at the executing node first, and then at the standby node.

Note that **Executing system** indicates the items to be executed at the executing node, **Standby system** indicates the items to be executed at the standby node, and **Optional** indicates the following setup items:

- Setup items that are required depending on the environment in use

- Setup items for changing the default settings

The following subsections describe how to cancel the setup of PFM - RM for Platform.

(1) Terminating from the cluster software Executing system Standby system

Use the cluster software to stop all the Performance Management programs and services running on the executing and standby nodes.

For details about how to stop programs and services, see the cluster software documentation.

(2) Mounting the shared disk Executing system

Make sure that the shared disk is mounted.

If the shared disk is not mounted, use a program such as the cluster software or a volume manager to mount it.

Note

If the shared disk is unmounted but the environment directory on the logical host whose setup is to be canceled contains the `jplpc` directory and there are files under the `jplpc` directory, the setup cancellation is performed without unmounting the shared disk. In this case, perform the following procedure:

1. Use the `tar` command to archive the `jplpc` directory that is located in the environment directory on the logical host whose setup is to be canceled on the local disk.
2. Mount the shared disk.
3. If the environment directory on the logical host whose setup is to be canceled does not exist on the shared disk, create an environment directory.
4. Expand the `tar` file in the environment directory on the logical host whose setup is to be canceled on the shared disk.
5. Unmount the shared disk.
6. Delete all files and directories under the `jplpc` directory that is located in the environment directory on the logical host whose setup is to be canceled on the local disk.

(3) Releasing the port number settings Executing system Optional

This procedure is required only if the `jpcconf port define` command was used to set port numbers during setup in an environment that uses a firewall.

For details about how to release port numbers, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide* and the chapter that describes configuration and operation of cluster systems in the *JPI/Performance Management User's Guide*.

(4) Canceling setup of the logical host for PFM - RM for Platform Executing system

This subsection describes how to cancel the setup of the logical host.

If a logical host environment is deleted while the shared disk is in offline status, the logical host settings are deleted from the physical host, but the directories and files are not deleted from the shared disk. In such a case, you must place the shared disk online and manually delete the `jplpc` directory under the environment directory.

To cancel the setup of the logical host for PFM - RM for Platform:

1. Execute the `jpcconf ha list` command to check the logical host settings.

Execute the following command:

```
jpcconf ha list -key all -lhost logical-host-name
```

You must check the current settings before you cancel the setup of the logical host environment. Check such information as the name of the logical host and the path to the shared disk.

2. Execute the `jpcconf target unsetup` command to delete information about the monitoring host for PFM - RM for Platform.

Execute the following command:

```
jpcconf target unsetup -key RMPlatform -lhost logical-host-name -inst  
instance-name -target monitoring-target-name
```

The `jpcconf target unsetup` command excludes the specified monitored host on the logical host as a monitoring target.

3. Execute the `jpcconf inst unsetup` command to delete the instance environment for PFM - RM for Platform.

Execute the following command:

```
jpcconf inst unsetup -key RMPlatform -lhost logical-host-name -inst  
instance-name
```

This example shows execution in the interactive mode, but you can also execute the `jpcconf inst unsetup` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

The `jpcconf inst unsetup` command deletes the settings for starting the instance of the logical host. It also deletes files for the instance from the shared disk.

4. Execute the `jpcconf ha unsetup` command to delete the logical host environment for PFM - RM for Platform.

Execute the following command:

```
jpcconf ha unsetup -key RMPlatform -lhost logical-host-name
```

The `jpcconf ha unsetup` command deletes the settings for starting PFM - RM for Platform on the logical host. It also deletes files for the logical host from the shared disk.

5. Execute the `jpcconf ha list` command to check the logical host settings.

Execute the following command:

```
jpcconf ha list -key all
```

Make sure that PFM - RM for Platform has been deleted from the logical host environment.

(5) Canceling setup of the logical host for other Performance Management programs

If you are also canceling from the same logical host the setup of Performance Management programs other than PFM - RM for Platform, do so at this stage.

For details about the procedure for canceling the setup, see the chapter that describes configuration and operation of cluster systems in the *JPI/Performance Management User's Guide*. Also see the chapter that describes cluster system operation in each PFM - RM manual or PFM - Agent manual.

(6) Exporting the logical host environment definition file Executing system

After you have deleted the logical host environment for PFM - RM for Platform, export the environment definition to a file.

Performance Management achieves a matching environment in the executing and standby nodes by importing and exporting environment definitions. When the environment definition exported from the executing node (definition from which the Performance Management definition has been deleted) is imported to the standby node, the system compares it with the environment definition existing in the standby node (definition that still contains the Performance Management definition) to determine the differences (the portion deleted at the executing node), and then deletes the Performance Management environment definition.

To export the logical host environment definition file:

1. Execute the `jpcconf ha export` command to export the logical host environment definition.

Output the logical host environment definition information for Performance Management to an export file. You can assign any name to the export file. For example, to export the logical host environment definition to the `lhostexp.txt` file, execute the following command:

```
jpcconf ha export -f lhostexp.txt
```

This example shows execution in the interactive mode, but you can also execute the `jpcconf ha export` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

(7) Copying the logical host environment definition file to the standby node Executing system Standby system

Copy from the executing node to the standby node the logical host environment definition file that was exported in [\(6\) Exporting the logical host environment definition file](#).

(8) Unmounting the shared disk Executing system Optional

Unmount the file system and finish the procedure.

If you will be using the shared disk after this procedure is completed, there is no need to unmount the file system.

(9) Importing the logical host environment definition file Standby system

Import to the standby node the export file that was copied from the executing node. At the standby node, there is no need to unmount the shared disk during the import processing.

To import the logical host environment definition file:

1. Execute the `jpcconf ha import` command to import the logical host environment definition.

Execute the following command:

```
jpcconf ha import -f lhostexp.txt
```

This example shows execution in the interactive mode, but you can also execute the `jpccconf ha import` command in the non-interactive mode. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*.

This command changes settings in such a manner that the environment for the standby node becomes the same as in the export file. As a result, the settings for starting PFM - RM for Platform on the logical host are deleted. If you have canceled the setup of other Performance Management programs on the logical host, those settings are also deleted. If a fixed port number was set by the `jpccconf port define` command during the setup, it is also released.

2. Execute the `jpccconf ha list` command to check the logical host settings.

Execute the following command:

```
jpccconf ha list -key all
```

Make sure that the displayed information is the same as when the `jpccconf ha list` command is executed at the executing node.

(10) Releasing the registration of PFM - RM for Platform from the cluster software

Executing system

Standby system

From the cluster software, delete the settings related to PFM - RM for Platform on the logical host.

For details about how to delete the settings, see the cluster software documentation.

(11) Deleting the settings from PFM - Manager

Executing system

Standby system

From PFM - Web Console, log in to PFM - Manager and delete the settings related to the PFM - RM for Platform that you want to unsetup.

To delete the settings from PFM - Manager:

1. Start the PFM - Manager service.

If the PFM - Manager service was stopped in [5.6.2\(1\) Terminating from the cluster software](#), use the cluster software to start the PFM - Manager service. For details about how to start the service, see the cluster software manual.

2. From PFM - Web Console, delete the agent.

3. Delete the agent information from PFM - Manager.

For example, if PFM - Manager is running on logical host `jp1-hal` and PFM - RM for Platform is running on logical host `jp1-halrmp`, execute the following command:

```
jpctool service delete -id service-ID -host jp1-halrmp -lhost jp1-hal
```

In *service-ID*, specify the service ID of the agent that is to be deleted.

4. Restart the PFM - Manager service.

For details about how to start services, see the chapter that describes startup and termination of Performance Management in the *JP1/Performance Management User's Guide*.

5. Apply the service information of PFM - Manager host.

To apply the deletion of the service information to the PFM - Web Console host, synchronize the agent information between the PFM - Manager host and the PFM - Web Console host. To synchronize the agent information, use the `jpctool service sync` command.

5.6.3 Uninstallation procedure in a cluster system (for UNIX)

Uninstall PFM - RM for Platform from both the executing node and the standby node.

The uninstallation procedure is the same as when a cluster system is not employed. For details about the procedure, see [3.4.3 Procedure for uninstalling the UNIX edition](#).

Notes

- Before you uninstall PFM - RM for Platform, stop all Performance Management programs and services at the node where PFM - RM for Platform is to be uninstalled.
- If you uninstall PFM - RM for Platform without deleting the logical host environment, the environment directories might remain. In such a case, manually delete the environment directories.

5.7 Changing the PFM - RM for Platform system configuration

When a change occurs, such as the monitoring target system's network configuration and host names, you must change the system configuration for PFM - RM for Platform.

When you change the system configuration for PFM - RM for Platform, you must also change the settings for PFM - Manager and PFM - Web Console. For details about how to change the system configuration for Performance Management, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*. When you rename a logical host, some additions of PFM - Agent require additional tasks. PFM - RM for Platform requires no additional tasks.

5.8 Changing the PFM - RM for Platform operation method in a cluster system

This section describes how to change the PFM - RM for Platform operation method in a cluster system.

For details about how to change the operation method for the entire Performance Management system, see the chapter that describes installation and setup in the *JP1/Performance Management Planning and Configuration Guide*.

5.8.1 Updating an instance environment in a cluster system

To update an instance environment in a cluster system, check the logical host name and instance name, and then update each setting for the instance environment. Perform the instance environment setup on the PFM - RM host at the executing node.

Check the information to be updated in advance by referencing [3.6.2 Updating an instance environment](#).

Use the `jpccconf ha list` command to check the logical host name and instance name; use the `jpccconf inst setup` command to update the instance environment.

To update multiple instance environments, repeat the procedure described below.

To update an instance environment:

1. Check the logical host name and instance name.

Execute the `jpccconf ha list` command specifying the service key that indicates the PFM - RM for Platform running in the instance environment that you want to update.

For example, to check the logical host name and instance name of PFM - RM for Platform, execute the following command:

```
jpccconf ha list -key all
```

If the set logical host name is `jp1-halrmp` and the instance name is `SDC1`, the command displays as follows:

Output example:

Logical Host Name	Key	Environment Directory	[Instance Name]
jp1-halrmp	RMPlatform	<i>path-of-logical-host</i>	SDC1

2. If services of PFM - RM for Platform are running in the instance environment that is to be updated, stop them from the cluster software.
3. If the shared disk was placed offline (or unmounted) in step 2, use a program such as the cluster software or a volume manager to place it online (or mount it).
4. Execute the `jpccconf inst setup` command specifying the service key that indicates PFM - RM for Platform in the instance environment that you want to update.

For example, to update the instance environment where the logical host name for PFM - RM for Platform is `jp1-halrmp` and the instance name is `SDC1`, execute the following command:

```
jpccconf inst setup -key RMPlatform -lhost jp1-halrmp -inst SDC1
```

This example shows execution in the interactive mode, but you can also execute the `jpccnf inst setup` command in the non-interactive mode. For details about how to execute this command in the non-interactive mode, see [3.1.4\(2\) Setting up an instance environment](#).

If you execute the `jpccnf inst setup` command in the non-interactive mode, skip step 5.

5. Update the instance environment for PFM - RM for Platform.

Enter the instance environment settings for PFM - RM for Platform according to the command's instructions. For details about each instance environment setting for PFM - RM for Platform, see [3.6.2 Updating an instance environment](#). The current settings are displayed (note that the value of `RMHost_Password` is not displayed). To not change a displayed value, simply press the return key. When all entries have been completed, the instance environment is updated.

6. Restart the services for the updated instance environment from the cluster software.

For details about how to start and stop services, see the chapter that describes startup and termination of Performance Management in the *JPI/Performance Management User's Guide*.

Important

To change the value of an item that cannot be updated, you must delete the instance environment, and then re-create it.

For details about the commands, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

5.8.2 Updating a monitoring target in a cluster system

To update a monitoring target in a cluster system, check the monitoring target name, and then update the monitoring target. Perform the monitoring target settings on the PFM - RM host at the executing node.

Check the information to be updated in advance by referencing [3.1.4\(3\) Setting the monitored host](#) for Windows and [3.2.4\(4\) Setting the monitored host](#) for UNIX.

Use the `jpccnf target list` command to check the monitoring target name; use the `jpccnf target display` command to check the settings for the monitoring target; use the `jpccnf target setup` command to update the monitoring target.

Note

When you update the monitoring target, there is no need to stop services of PFM - RM for Platform.

To update multiple monitoring targets, repeat the procedure described below.

To update the monitoring target:

1. Check the name of the monitoring target.

Execute the `jpccnf target list` command specifying the service key that indicates the PFM - RM for Platform that is monitoring the target to be updated, the logical host name, and the instance name.

For example, to check the name of the monitoring target for the PFM - RM for Platform whose logical host name is `jp1-halrmp` and instance name is `SDC1`, execute the following command:

```
jpccnf target list -key RMPlatform -lhost jp1-halrmp -inst SDC1
```

When this command is executed, the following information is displayed:

Output example:

```
Targets:
targethost1
targethost2
Groups:
All
```

2. Check the settings for the monitoring target.

Execute the `jpcconf target display` command specifying the service key that indicates the PFM - RM for Platform that is monitoring the target to be updated, the logical host name, the instance name, and the monitoring target name.

For example, to check the settings for the monitoring target whose name is `targethost1`, logical host name is `jp1-halrmp`, and instance name is `SDC1`, execute the following command:

```
jpcconf target display -key RMPlatform -lhost jp1-halrmp -inst SDC1 -target
targethost1
```

3. If the shared disk is in offline status (or is unmounted), use a program such as the cluster software or a volume manager to place it online (or mount it).

4. Execute the `jpcconf target setup` command specifying the service key that indicates the PFM - RM for Platform that is monitoring the target to be updated, the logical host name, the instance name, and the monitoring target name.

For example, to update the monitoring target whose name is `targethost1`, logical host name is `jp1-halrmp`, and instance name is `SDC1`, execute the following command:

```
jpcconf target setup -key RMPlatform -lhost jp1-halrmp -inst SDC1 -target
targethost1
```

This example shows execution in the interactive mode, but you can also execute the `jpcconf target setup` command in the non-interactive mode. For details about how to execute this command in the non-interactive mode, see [3.1.4\(3\) Setting the monitored host](#).

If you execute the `jpcconf target setup` command in the non-interactive mode, skip step 5.

5. Update the monitoring target of PFM - RM for Platform.

Enter the monitoring target information for PFM - RM for Platform according to the command's instructions. For details about the monitoring target information for PFM - RM for Platform, see [3.6.3 Updating a monitoring target](#). The current settings are displayed (note that the value of `Password` is not displayed). To not change a displayed value, simply press the return key. When all entries have been completed, the monitoring target is updated.

Important

To change the value of an item that cannot be updated, you must delete the monitoring target information, and then re-create it.

5.8.3 Importing and exporting the logical host environment definition file in a cluster system

Import and export the logical host environment definition file only if you have performed the following operations:

- You changed the node configuration on the logical host when you set up the logical host, instance environment, and monitoring target.

The following subsections show how to set up a logical host for PFM - RM for Platform:

- For Windows: See [5.3.4\(3\) Setting up a logical host environment for PFM - RM for Platform](#).
- For UNIX: See [5.4.4\(3\) Setting up a logical host environment for PFM - RM for Platform](#).

The following subsections show how to set up an instance environment:

- For Windows: See [5.3.4\(5\) Setting up an instance environment](#).
- For UNIX: See [5.4.4\(5\) Setting up an instance environment](#).

The following subsections show how to set up the monitoring target:

- For Windows: See [5.3.4\(6\) Setting the monitoring target](#).
- For UNIX: See [5.4.4\(6\) Setting the monitoring target](#).

- You executed an operation that requires export of the logical host environment definition file when you set up a logical host for other Performance Management programs.

The following subsections show how to set up the logical host for other Performance Management programs:

- For Windows: See [5.3.4\(7\) Setting up the logical host for other Performance Management programs](#).
- For UNIX: See [5.4.4\(7\) Setting up the logical host for other Performance Management programs](#).

- You set port numbers during network setup.

The following subsections show how to set up a network:

- For Windows: See [5.3.4\(8\) Setting up a network](#).
- For UNIX: See [5.4.4\(8\) Setting up a network](#).

The following subsections show how to export and import the logical host environment definition file:

- For Windows: See [5.3.4\(12\) Exporting the logical host environment definition file](#) through [5.3.4\(15\) Importing the logical host environment definition file](#).
- For UNIX: See [5.4.4\(12\) Exporting the logical host environment definition file](#) through [5.4.4\(15\) Importing the logical host environment definition file](#).

If you have only updated the instance environment and monitoring target, there is no need to import or export the logical host environment definition file.

For details about how to set up an instance environment, see [5.8.1 Updating an instance environment in a cluster system](#). For details about how to update the monitoring target, see [5.8.2 Updating a monitoring target in a cluster system](#).

6

Monitoring Template

This chapter describes the monitoring template for PFM - RM for Platform.

Overview of the monitoring template

A set of alarms and reports provided by PFM - RM for Platform is called a *monitoring template*. You can define alarms and reports by the following methods:

- Use the alarms and reports defined by PFM - RM for Platform
- Copy and customize the alarms and reports defined by PFM - RM for Platform
- Use a wizard to define new information

Because the necessary information for reports and alarms is predefined in the provided monitoring template, you can use the provided monitoring template as-is, or you can copy the provided template's reports and alarms and customize them as appropriate for your environment. Thus, it is not necessary to use the wizard to create new definitions, which simplifies the preparations for monitoring the operation status of a monitoring target.

This chapter describes the alarm and report settings in the monitoring template that have been defined by PFM - RM for Platform.

For details about how to use the monitoring template, see the chapter that describes report creation for operation analysis or operation monitoring by alarms in the *JP1/Performance Management User's Guide*.

Note:

The threshold value specified in the monitoring template is for reference only. To use the alarm from the monitoring template, you need to copy it and specify a threshold value that is appropriate to your environment and OS.

Format of alarm explanations

This section describes the format used to explain alarms. The alarms are presented in alphabetical order.

Alarm name

Indicates the alarm's name in the monitoring template.

Overview

Provides an overview of the target that can be monitored by the alarm.

Main settings

Explains in tabular format the main settings for this alarm.

This table lists the correspondence between settings on the Properties window of PFM - Web Console and the alarm settings defined in the monitoring template.

To display the Properties window in PFM - Web Console, click the alarm icon on the **Alarms** page, and then click the **Properties** method. For details about the settings for each alarm, check the Properties window.

If the abnormal condition is the same as the warning condition in a conditional expression, the system issues only the abnormal alarm event.

Alarm table

Indicates the alarm table that contains this alarm.

Related reports

Indicates the reports in the monitoring template that are associated with this alarm.

To display these reports in PFM - Web Console, on the **Agents** page, click the agent icon, and then click the  icon displayed in the **Display Alarm Status** method.

List of alarms

A table containing one or more alarms is called an *alarm table*. The alarms defined in the monitoring template of PFM - RM for Platform are in alarm table format and are stored in the `RM Platform` folder that is displayed on the **Alarms** page of PFM - Web Console.

The alarm table name is as follows:

- PFM RM Platform Template Alarms 09.10
- PFM RM Platform Template Alarms [APP] 09.10
- PFM RM Platform Template Alarms [PS] 09.10
- PFM RM Platform Template Alarms [SVC] 09.10

Item in square brackets ([]) in an alarm name

Square brackets ([]) indicate the monitoring item to which the alarm table corresponds. An alarm table without square brackets ([]) is an alarm table that groups other basic alarms.

09.10 at the end of the alarm table name

The numerics (09.10) at the end of the alarm table name indicate the alarm table's version number.

When you use alarms defined in the monitoring template, check the version of the alarm table used in the Performance Management system for version compatibility. For details about the alarm table version and version compatibility, see [H. Version Compatibility](#).

The following table lists (in alphabetical order) and describes the alarms defined in the monitoring template of PFM - RM for Platform.

Table 6–1: List of alarms

Alarm table name	Alarm name	Monitoring target	Purpose
PFM RM Platform Template Alarms 09.10	Available Memory	Size of the unused physical memory area (megabytes)	Monitoring operation status
	CPU Usage	Processor usage rate (%)	Monitoring performance data
	Disk Busy %	Percentage of time the disk was busy (%)	
	Disk Free Size	Size of the unused area on the logical disk (in megabytes)	Monitoring operation status
	Disk Service Time	Device usage (in busy status)	Monitoring performance data
	Disk Space	Ratio of the free area on the logical disk to the total available area (%)	Monitoring operation status
	I/O Wait Time	Percentage of the time all processors in the entire host were in I/O wait status (%)	Monitoring performance data
	Kernel CPU	Percentage of the time all processors in the entire host were running in the kernel mode (%)	
	Network Received	Rate of data received by the network interface (bytes/second)	
	Page Faults	Page fault count	
	Pagescans	Page scan rate	

Alarm table name	Alarm name	Monitoring target	Purpose
PFM RM Platform Template Alarms 09.10	Processor Queue	Number of requests in the processor queue that are ready for execution	Monitoring performance data
	Run Queue	Number of threads in the execution queue	
	Swap Outs	Number of pages that were swapped out	
	Target Host Status	Status of the connection to the monitored host	Monitoring operation status
	Used Swap Mbytes	Size of the memory used in the virtual memory area (in megabytes)	
	User CPU	Percentage of the time all processors in the entire host were running in the user mode (%)	Monitoring performance data
PFM RM Platform Template Alarms [PS] 09.10	Process Existence	Program name	Monitoring operation status
PFM RM Platform Template Alarms [SVC] 09.10	Service Stop	Service name used in the service control manager database and the service status at the time of data collection	
	Service Stop(dsp nm)	Name used by the user interface program to identify a service and the service status at the time of data collection	
PFM RM Platform Template Alarms [APP] 09.10	Application Status	Status of the application being monitored by the Application Summary (PD_APP2) record	

PFM - RM for Platform provides in the monitoring template various alarms for monitoring the operation status in order to determine whether the system is running normally, as well as alarms for monitoring performance data in order to determine whether the system is providing adequate services. You can set use of the alarms that are appropriate to your purposes.

Note

Some fields used in alarms might not be supported by the OS of the monitored host. Do not use alarm fields that are not supported.

The following table shows which alarm fields are supported by the monitored host OSs.

Table 6–2: Support status of alarm fields (monitoring template)

Alarm name	OS of the monitored host					When an unsupported alarm is used by the OS
	Windows	HP-UX	Solaris	AIX	Linux	
Available Memory	Y	Y	Y	Y	Y	--
CPU Usage	Y	Y	Y	Y	Y	--
Disk Busy %	Y	Y	Y	Y	Y	--

Available Memory

Overview

The Available Memory alarm monitors the unused size of the physical memory area (in megabytes).

The monitored value is the total size of zero memory, available memory, and standby memory (already cached) that can be allocated to processes or that can be used immediately by the system during collection. This is the most recent monitored value, not an average value.

Main settings

Table 6–4: Alarm property settings in PFM - Web Console (Available Memory)

	Alarm message	Used swap is %CVS megabytes
	Enable alarm	Selected
	Alarm notification	Notify when the state changed
	Notification target	State changes for the alarm
	Evaluate all data	Do not specify.
	Monitoring time range	Always monitor
	Report alarm when the following damping condition is reached	Selected
	occurrence(s) during	2
	interval(s)	3
Alarm Conditions	Record	System Summary (PI)
	Field	Used Swap Mbytes
	Abnormal condition	Used Swap Mbytes >= 1024 ^{#1}
	Warning condition	Used Swap Mbytes >= 1024 ^{#2}
Actions	Email	--
	Command	--
	SNMP	Abnormal, Warning, Normal

Legend:

--: The setting is always ignored.

#1

A guideline for the value to be set is about 90% of the value set for Total Swap Mbytes.

#2

Set the same value as for Total Mem Mbytes.

Note

1024 is set as the value for this alarm for both abnormal and warning conditions. To use this alarm, change the values for abnormal and warning conditions as appropriate to the user's environment.

User CPU

Overview

The User CPU alarm monitors the percentage of the time all processors in the entire host were running in the user mode.

Main settings

Table 6–23: Alarm property settings in PFM - Web Console (User CPU)

Alarm properties in PFM - Web Console		Setting
Item	Details	
Main Information	Product	RM Platform
	Alarm message	User mode CPU usage is %CVS%
	Enable alarm	Selected
	Alarm notification	Notify when the state changed
	Notification target	State changes for the alarm
	Evaluate all data	Do not specify.
	Monitoring time range	Always monitor
	Report alarm when the following damping condition is reached	Selected
	occurrence(s) during	2
	interval(s)	3
Alarm Conditions	Record	System Summary (PI)
	Field	User %
	Abnormal condition	User % > 85
	Warning condition	User % > 65
Actions	Email	--
	Command	--
	SNMP	Abnormal, Warning, Normal

Legend:

--: The setting is always ignored.

Format of report explanations

This section describes the format used to explain reports. The reports are presented in alphabetical order.

Report name

Indicates the report's name in the monitoring template.

A report whose name includes (Multi-Agent) displays information about multiple instances.

A report whose name does not include (Multi-Agent) displays information about a single instance.

Overview

Provides an overview of the information that can be displayed in the report.

Storage location

Indicates the storage location of the report.

Record

Indicates the record that contains the performance data used in the report. To display a historical report, you must specify information in advance in order to collect the indicated record. Before displaying a historical report, check the Agents window in PFM - Web Console to see if **Log** is set to **Yes**. This setting is not needed to display a real-time report.

Fields

Provides a table that describes the fields used in the report.

Drilldown reports (report level)

Provides a table that lists other reports in the monitoring template that are related to this report. To display these drilldown reports, in the PFM - Web Console Report window, select the name of the desired drilldown report from the drilldown report drop-down list, and then click **Display Reports**. Note that some reports do not have any drilldown reports.

Drilldown reports (field level)

Provides a table that describes reports in the monitoring template that are associated with fields used in this report. To display these drilldown reports, in the PFM - Web Console Report window, choose **Graph**, **List**, or **Table**. In the case of a historical report, you can display the drilldown report in smaller intervals by displaying it from the time item. Note that some reports do not have any drilldown reports.

For details about the drilldown reports, see the chapter that describes report creation for operation analysis in the *JPI/Performance Management User's Guide*.

Organization of report directories

The following shows the organization of the report directories for PFM - RM for Platform. Angle brackets enclose directory names.

```
+++ <RM Platform>
  +++ <Monthly Trend>

The following describes each directory.

Monthly Trend directory

This directory contains reports that display daily information for the past month. Use the reports in this directory to check monthly trends in the system.

Status Reporting directory

This directory contains reports that display daily information. Use the reports in this directory to check the overall status of the system. You can display real-time reports as well as historical reports.

Daily Trend directory

This directory contains reports for displaying hourly information for the past 24 hours. Use the reports in this directory to check the daily status of the system.

Real-Time directory

This directory contains real-time reports for checking the system status.

Troubleshooting directory

This directory contains reports for displaying information that is useful for resolving problems. In the event of a system problem, use the reports in this directory to check the cause of the problem.

Real-Time directory

This directory contains real-time reports for checking the current system status.

Recent Past directory

This directory contains historical reports for displaying minute-by-minute information for the past hour.

These directories also contain the following directory:

Drilldown Only directory

This directory contains a report that is displayed as a drilldown (field level) report. It is used to display the detailed information related to the fields of the main report.

List of reports

The following table lists and describes the reports defined in the monitoring template for PFM - RM for Platform.

Table 6–24: List of reports

Category	Report name	Displayed information
System	System Overview (real-time report indicating the system operation status)	Displays the current operation status of the system.
	System Overview (historical report indicating the system operation status)	Displays the minute-by-minute system operation status over the past hour.
	Target Host Status (historical report indicating the status of the connection to the monitored host and information about the OS of the monitored host)	Displays the minute-by-minute status of the connection to the monitored host and information about the OS of the monitored host over the past hour.
Disk	Avg Disk Time Status (real-time report indicating the average I/O time for the physical disk)	Displays the current average I/O operation time for the physical disk.
	Avg Disk Time Status (historical report indicating the average I/O time for the physical disk)	Displays minute-by-minute the average I/O operation time for the physical disk over the past hour.
	Free Megabytes - Logical Disk (real-time report indicating the available area on the logical disk)	Displays information about the area that is currently available on the logical disk.
	Free Megabytes - Logical Disk (historical report indicating the available area on the logical disk)	Displays minute-by-minute information about the area that is available on the logical disk over the past hour.
	Physical Disk Busy Status (real-time report indicating the length of time the disk was busy)	Displays the percentage of time the current disk was busy.
	Physical Disk Busy Status (historical report indicating the length of time the disk was busy)	Displays minute-by-minute information about the percentage of time the disk was busy over the past hour.
Network	Network Data (real-time report indicating the status of communication between networks)	Displays the current status of communication between networks.
	Network Data (historical report indicating the status of communication between networks)	Displays the minute-by-minute status of communication between networks over the past hour.
Processor	CPU Per Processor Status (real-time report indicating the processor usage rate for each processor)	Displays the current processor usage rate for each processor.
	CPU Used Status (real-time report indicating the CPU usage status)	Displays the current CPU usage status in the system.
	CPU Used Status (historical report indicating the CPU usage status (1 month))	Displays the daily CPU usage status over the past month.
	CPU Used Status (historical report indicating the CPU usage status (1 hour))	Displays the minute-by-minute CPU usage status in the system over the past hour.
	CPU Used Status (Multi-Agent) (historical report indicating the CPU usage status in multiple systems (1 month))	Displays the daily CPU usage status in multiple systems over the past month.
	CPU Used Status (Multi-Agent) (historical report indicating the CPU usage status in multiple systems (1 day))	Displays the hourly CPU usage status in multiple systems over the past day (24 hours).
Memory	Memory Paging Status (real-time report indicating information about memory and paging)	Displays current information about memory and paging.

Category	Report name	Displayed information
Memory	Memory Paging Status (historical report indicating information about memory and paging (1 day))	Displays hourly information about memory and paging over the past day (24 hours).
	Memory Paging Status (historical report indicating information about memory and paging (1 hour))	Displays minute-by-minute information about memory and paging over the past hour.
	Memory Used Status (real-time report indicating the physical memory usage status in the system)	Displays the current physical memory usage status in the system.
	Memory Used Status (historical report indicating the physical memory usage status in the system (1 day))	Displays the hourly physical memory usage status in the system over the past day (24 hours).
	Memory Used Status (historical report indicating the physical memory usage status in the system (1 hour))	Displays the minute-by-minute physical memory usage status in the system over the past hour.
	Memory Used Status (Multi-Agent) (historical report indicating the physical memory usage status in multiple systems (1 month))	Displays the daily physical memory usage status in multiple systems over the past month.
	Memory Used Status (Multi-Agent) (historical report indicating the physical memory usage status in multiple systems (1 day))	Displays the hourly physical memory usage status in multiple systems over the past day (24 hours).
	Pool Nonpaged Status (real-time report indicating the size of the physical memory in the system that cannot be paged out)	Displays the current size of the physical memory in the system that cannot be paged out.
	Pool Nonpaged Status (historical report indicating the size of the physical memory in the system that cannot be paged out)	Displays the minute-by-minute size of the physical memory in the system that cannot be paged out over the past hour.
Process	Application Status (real-time report indicating the operation status of an application)	Displays the current operation status of an application.
	Application Process Status (real-time report indicating the operation status of each process and service of an application)	Displays the current operation status of each process and service of an application.
	Application Process Count (historical report indicating the operation status of each process and service of an application)	Displays a summary of the minute-by-minute operation status of each process and service of an application collected over the past hour.

Application Process Count (historical report indicating the operation status of each process and service of an application)

Overview

The Application Process Count report displays a summary of the minute-by-minute operation status of each process and service of an application collected over the past hour. The display format is a line graph. This report is a drilldown report.

Storage location

Fields

Table 6–25: Description of fields (Application Process Count (historical report indicating the operation status of each process and service of an application))

Field name	Description
Application Name	Application definition name specified during process monitoring setup
Monitoring Count	Number of running processes and services that match the monitoring condition
Monitoring Label	Name for identifying a specific monitoring condition
Monitoring Max	Maximum monitoring count
Monitoring Min	Minimum monitoring count
Monitoring Number	Monitoring condition number
Monitoring Status	Conditional result of the monitoring count NORMAL: No problem ABNORMAL: Abnormal
Polling Time	Time when the performance information was collected on the PFM - RM host
Target Host Time	Time when the performance information was collected on the monitored host

Application Process Status (real-time report indicating the operation status of each process and service of an application)

Overview

The Application Process Status report displays the current operation status of each process and service of an application. This is a drilldown report.

Storage location

/RM Platform/Troubleshooting/Real-Time/Drilldown Only

Record

Fields

Table 6–26: Description of fields (Application Process Status (real-time report indicating the operation status of each process and service of an application))

Field name	Description
Application Name	Application definition name specified during process monitoring setup
Monitoring Condition	Conditional expression for identifying specific processes and services to be monitored
Monitoring Count	Number of running processes and services that match the monitoring condition
Monitoring Field	Field to be monitored
Monitoring Label	Name for identifying a specific monitoring condition
Monitoring Max	Maximum monitoring count
Monitoring Min	Minimum monitoring count
Monitoring Number	Monitoring condition number
Monitoring Status	Conditional result of the monitoring count NORMAL: No problem ABNORMAL: Abnormal
Polling Time	Time when the performance information was collected on the PFM - RM host
Target Host Time	Time when the performance information was collected on the monitored host

Drilldown report (field level)

Table 6–27: Description of drilldown report (field level) (Application Process Status (real-time report indicating the operation status of each process and service of an application))

Report name	Description
Application Process Count	Displays a summary of the minute-by-minute operation status of each process and service of an application collected over the past hour. To display this report, click the Monitoring Count field.

Application Status (real-time report indicating the operation status of an application)

Overview

The `Application Status` report displays the current operation status of an application. The display format is a table.

Storage location

/RM Platform/Troubleshooting/Real-Time

Record

PD_APP2

Fields

Table 6–28: Description of fields (Application Status (real-time report indicating the operation status of an application))

Field name	Description
Application Exist	Application status specified during process monitoring setup. An application status is a result obtained based on the statuses of the processes and services specified as monitoring targets. To check the statuses of the processes and services specified as monitoring targets, see <code>Monitoring Status</code> displayed in the Application Process Count (PD_APPC) record and Application Process Detail (PD_APPD) record. NORMAL: The status of at least one of the monitoring targets is normal. ABNORMAL: The statuses of all monitoring targets are abnormal.
Application Name	Application definition name specified during process monitoring setup
Application Status	Application status specified during process monitoring setup. An application status is a result obtained based on the statuses of the processes and services specified as monitoring targets. To check the statuses of the processes and services specified as monitoring targets, see <code>Monitoring Status</code> displayed in the Application Process Count (PD_APPC) record and Application Process Detail (PD_APPD) record. NORMAL: The statuses of all monitoring targets are normal. ABNORMAL: The status of at least one of the monitoring targets is abnormal.
Polling Time	Time when the performance information was collected on the PFM - RM host
Target Host Time	Time when the performance information was collected on the monitored host

Drilldown report (field level)

Table 6–29: Description of drilldown report (field level) (Application Status (real-time report indicating the operation status of an application))

Report name	Description
Application Process Status	Displays the current operation status of each process and service of an application. To display this report, click the Application Name field.

Avg Disk Time Status (real-time report indicating the average I/O time for the physical disk)

Overview

The Avg Disk Time Status report displays the current average I/O operation time for the physical disk. The display format is a bar graph.

The CPU Per Processor Status report displays the current processor usage rate for each processor. The display format is a stacked bar graph.

Storage location

/RM Platform/Troubleshooting/Real-Time

Record

PI_CPU

Fields

Table 6–32: Description of fields (CPU Per Processor Status (real-time report indicating the processor usage rate for each processor))

Field name	Description
CPU %	Processor's CPU usage rate (%)
ID	Processor ID
Idle %	Percentage of the time the processor was in idle status (%)
Interrupt Counts/sec	In Windows: Frequency of hardware interrupt reception processing performed by the processor (times/second); <i>hardware</i> refers to devices that generate interrupts, such as the system clock, mouse, disk driver, data communication line, NIC, and other peripheral devices. This value does not include DPC (delayed procedure call) interrupts. Normally, if the value of this field increases greatly while there is no system activity, a hardware problem is suspected (such as a slow device). In UNIX: Frequency of interrupts (times/second)
Polling Time	Time the performance data was collected on the PFM - RM host
System %	Usage rate for a processor that was executed in the kernel mode (%)
Target Host Time	Time the performance data was collected on the monitored host
User %	Usage rate for a processor that was executed in the user mode (%)
Wait %	Percentage of the time the processor was in I/O wait status (%)

CPU Used Status (real-time report indicating the CPU usage status)

Used Swap Mbytes	<p>In Windows: Size of the virtual memory area used (committed) (megabytes)</p> <p>In UNIX: Size of the swap area used (megabytes)</p>

Memory Paging Status (historical report indicating information about memory and paging (1 day))

Overview

The Memory Paging Status report displays hourly information about memory and paging over the past day (24 hours). The display format is a line graph.

Storage location

/RM Platform/Status Reporting/Daily Trend

Record

PI

Fields

Table 6–43: Description of fields (Memory Paging Status (historical report indicating information about memory and paging (1 day)))

Field name	Description
Free Swap %	In Windows: Percentage of unused space in the virtual memory area (%) In UNIX: Percentage of unused space in the swap area (%)
Free Swap Mbytes	In Windows: Size of the unused space in the virtual memory area (megabytes) In UNIX: Size of the unused space in the swap area (megabytes)
Page Fault Counts/sec	Frequency of page faults (times/second)
Page-In Pages/sec	Rate at which pages were paged in (pages/second)
Page-Out Pages/sec	Rate at which pages were paged out (pages/second)
Page Scan Counts/sec	Frequency of page scans (times/second)
Paging Pages/sec	Rate at which pages were being paged in and out when a page fault occurred (pages/second). This is the total of the Page-In Pages/sec and Page-Out Pages/sec fields. If this value exceeds 5 continuously, the memory might be the bottleneck in the system.
Total Swap Mbytes	In Windows: Size of the virtual memory area (megabytes) In UNIX: Size of the swap area (megabytes)
Used Swap %	In Windows: Virtual memory usage rate (%) In UNIX: Swap area usage rate (%)
Used Swap Mbytes	In Windows: Size of the virtual memory area used (committed) (megabytes)

Field name	Description
Used Swap Mbytes	In UNIX: Size of the swap area used (megabytes)

7

Records

This chapter describes the records for PFM - RM for Platform. For details about how to collect performance data for each record, see the chapter that describes the functions of Performance Management in the *JP1/Performance Management Planning and Configuration Guide* or the chapter that describes the management of operation monitoring data in the *JP1/Performance Management User's Guide*.

Data model

The records and fields of PFM - RM for Platform are referred to collectively as a *data model*. A specific version number is assigned to the data model for PFM - RM for Platform.

For details about the relationship between the PFM - RM for Platform version and the data model version, see [H. Version Compatibility](#).

To check the data model version of your PFM - RM for Platform, use the Properties window of PFM - Web Console. To open the Properties window, on the **Agents** page of PFM - Web Console, click the agent icon, and then click the **Properties** method.

For details about the data model, see the chapter that describes the functions of Performance Management in the *JP1/Performance Management Planning and Configuration Guide*.

Format of record explanations

The records for PFM - RM for Platform are described in this chapter in alphabetical order.

Each record explanation contains the following subsections:

Function

Provides an overview of the performance data that is stored in the record and includes important information that should be noted.

Default and changeable values

Consists of a table of the default values for the performance data collection conditions that are defined for the record, and indicates whether each value can be changed by the user.

The table below lists and describes the items that are presented in *Default and changeable values*. For details about each item described in this table, see the chapter that describes the management of operation monitoring data in the *JPI/Performance Management User's Guide*.

Table 7–1: Default and changeable values (record)

Item	Description	Changeable
Collection Interval	Performance data collection interval (in seconds)	Y: Changeable N: Not changeable
Collection Offset ^{#1}	Delay (offset value) for starting performance data collection (in seconds). For details about the offset value, see the chapter that describes the management of operation monitoring data in the <i>JPI/Performance Management User's Guide</i> . For details about the performance data collection start time, see the chapter that describes the functions of Performance Management in the <i>JPI/Performance Management Planning and Configuration Guide</i> .	
Log	Whether collected performance data is stored in the Store database: Yes: Stored. However, if Collection Interval=0 is set, no collected performance data is stored. No: Not stored.	
LOGIF	Conditions for storing collected performance data in the Store database	
Over 10 Sec Collection Time ^{#2}	Whether record collection takes 10 seconds or longer Yes: Record collection sometimes takes 10 seconds or longer. No: Record collection takes less than 10 seconds.	
Realtime Report Data Collection Mode ^{#2}	Specifies the real-time report display mode. Reschedule: Reschedule mode Temporary Log: Temporary log mode Note that you must specify the temporary log mode (Temporary Log) for records for which Over 10 Sec Collection Time is set to Yes.	
Sync Collection With ^{#3}	Whether performance data is to be collected along with the record displayed in the Description record property. For details, see the chapter that	

Item	Description	Changeable
Sync Collection With ^{#3}	describes management of operation monitoring data in the <i>JPI/Performance Management User's Guide</i> .	Y: Changeable N: Not changeable

#1

The value must be in the range from 0 to 32,767 seconds (but within the collection interval specified in `Collection Interval`). This value is used to distribute the workload of collection processing so as to avoid concentration of the workload when multiple data items are collected. Note that the recording time for data collection is the same as for `Collection Interval` regardless of the `Collection Offset` value.

To change the `Collection Offset` value, specify an appropriate value taking into account the workload of collection processing.

#2

This item is displayed when historical data collection takes priority over real-time report display processing. For details, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

#3

When `Sync Collection With` is displayed, `Collection Interval` and `Collection Offset` are not displayed.

ODBC key field

Indicates the primary key required for PFM - Manager to use the record data stored in the Store database. Some ODBC key fields are common to all records, and some are specific to individual records. This section presents the ODBC key field that is specific to each record. Note that only multi-instance records have a specific ODBC key field.

Lifetime

Indicates the period during which consistency is guaranteed for the performance data that is collected in the record.

For details about the lifetime, see the chapter that describes the functions of Performance Management in the *JPI/Performance Management Planning and Configuration Guide*.

Record size

Indicates the amount of performance data that can be collected and stored in the record during a single collection operation.

Fields

Provides a table that describes the record's fields. The table contains the following columns:

PFM - View name (PFM - Manager name)

PFM - View name

Indicates the field name (PFM - View name) that is displayed with PFM - Web Console.

PFM - Manager name

Indicates the field name (PFM - Manager name) to be specified in SQL statements when statements are used from PFM - Manager to access the field data stored in the Store database.

Specify the record ID at the beginning of an SQL statement. For example, to specify the Polling Time (`POLLING_TIME`) field of the System Status (PD) record, specify `PD_POLLING_TIME`.

Description

Describes the performance data that is stored in each field.

The performance data in each field can be obtained in the following ways:

- Obtaining an average or a rate from the current data and the data collected during the previous interval

- Obtaining by using only the current data that has been collected
- Obtaining from the data in other fields

The value obtained at the set data collection interval is used, unless indicated otherwise.

When records of the PI record type are summarized for a historical report with a value other than *minute* specified as the reporting interval, the following types of values can be displayed:

- Average value over the summarized intervals
- Last value collected
- Total value
- Minimum value
- Maximum value

A displayed field value is the average value over the summarized intervals, unless indicated otherwise.

Summary rule

Indicates the summarization method used by Remote Monitor Store to summarize the data. This summarization method is referred to as the *summary rules*. For summarization rules, see [Summarization rules](#).

Grouping rule

Indicates the method for consolidating performance information for remote agents that belong to the same instance. This summarization method is referred to as the *grouping rules*. For grouping rules, see [Grouping rules](#).

Format

Indicates the data type of the field's value. For data types, see [List of data types](#).

Delta

Indicates whether the value is a delta value. In contrast to data collected as a cumulative value, data expressed by the amount the value has changed is called a *delta*. For details about deltas, see [Field values](#).

Unsupported

Indicates the OSs of the monitored host that do not support use of the field.

List of ODBC key fields

Some ODBC key fields are common to all records, and some are specific to individual records. This section presents the ODBC key fields common to all records. For PFM - Manager to use the record data stored in the Store database, ODBC key fields are required.

The table below lists the ODBC key fields that are common to all records. For details about the ODBC key fields specific to individual records, see the details for each record.

Table 7–2: List of ODBC key fields common to all records

ODBC key field	ODBC format	Data	Description
<i>record-ID</i> _DATE	SQL_INTEGER	Internal	Key in the record that indicates the record creation date
<i>record-ID</i> _DATETIME	SQL_INTEGER	Internal	Combination of the <i>record-ID</i> _DATE and <i>record-ID</i> _TIME fields
<i>record-ID</i> _DEVICEID	SQL_VARCHAR	Internal	Indicates one of the following: <ul style="list-style-type: none"><i>instance-name</i> [<i>monitored-host -name</i>@<i>PFM-RM-host-name</i>]<i>instance-name</i> [<i>all</i>@<i>PFM-RM-host-name</i>]
<i>record-ID</i> _DRAWER_TYPE	SQL_VARCHAR	Internal	Type. Valid values are as follows: <ul style="list-style-type: none">m: MinuteH: HourD: DayW: WeekM: MonthY: Year
<i>record-ID</i> _PROD_INST	SQL_VARCHAR	Internal	Instance name of PFM - RM for Platform
<i>record-ID</i> _PRODID	SQL_VARCHAR	Internal	Product ID of PFM - RM for Platform
<i>record-ID</i> _RECORD_TYPE	SQL_VARCHAR	Internal	Identifier indicating the record type (4 bytes)
<i>record-ID</i> _TIME	SQL_INTEGER	Internal	Record creation time (Greenwich mean time)

Summarization rules

For records of the PI record type, the data that is collected is stored in the Store database. This includes data collected at the interval set in `Collection Interval`, as well as data that is collected on a specific interval basis derived from defined rules (such as minute, hour, day, week, month, or year). The type of summarization is defined for each field; this definition is referred to as the *summary rules*.

Some summary rules require intermediate data to be retained during the summarization period. In such a case, a field for retaining the intermediate data is added to the record in the Store database; this is called an *added field*. Some added fields are displayed as record fields in PFM - Web Console. These added fields that are displayed in PFM - Web Console can be used as fields for display in historical reports.

As distinguished from the *added fields* that are created by summarization, the fields described in each record explanation are called *fixed fields*.

The name of an added field is as follows:

- Name of an added field that is stored in the Store database
PFM - Manager name of the fixed field with a suffix
- Name of an added field that is displayed in PFM - Web Console
PFM - View name of the fixed field with a suffix

The following table lists the suffixes for the PFM - Manager name, the suffixes for the corresponding PFM - View name, and the data that is stored in each field.

Table 7–3: List of suffixes for added fields

Suffix for PFM - Manager name	Suffix for PFM - View name	Stored data
<code>_TOTAL</code>	<code>(Total)</code>	Sum of the field's value in the records over the summary period
<code>_COUNT</code>	--	Number of records collected during the summary period
<code>_HI</code>	<code>(Max)</code>	Maximum field value in the records over the summary period
<code>_LO</code>	<code>(Min)</code>	Minimum field value in the records over the summary period

Legend:

--: There is no added field.

The following table lists and describes the summary rules.

Table 7–4: List of summary rules

Summary rule name	Description of summary rule
<code>COPY</code>	Stores the field value in the most recent record in the summary period.
<code>AVG</code>	<p>Stores the average field value in the summary period.</p> <p>The formula is as follows:</p> $\text{Sum-of-field-values} / \text{number-of-collected-records}$ <p>Added fields (Store database):</p> <ul style="list-style-type: none">• <code>_TOTAL</code>• <code>_COUNT</code> <p>Added field (PFM - Web Console):</p> <ul style="list-style-type: none">• <code>(Total)</code>

Summary rule name	Description of summary rule
HILO	<p>Stores the maximum, minimum, and average field values in the summary period.</p> <p>In the fixed field, the average value is stored.</p> <p>The formula is as follows:</p> $\text{Sum-of-field-values} / \text{number-of-collected-records}$ <p>Added fields (Store database):</p> <ul style="list-style-type: none"> • _HI • _LO • _TOTAL • _COUNT <p>Added fields (PFM - Web Console):</p> <ul style="list-style-type: none"> • (Max) • (Min) • (Total)
--	Indicates that data is not summarized.

Grouping rules

Performance data for the monitored hosts in the same instance environment is summarized as the data for the group agent based on predefined rules. This definition is referred to as the *grouping rules*.

The following table lists the grouping rules.

Table 7–5: List of grouping rules

Grouping rule name	Description of grouping rule
ADD	Stores the sum of all the performance data for the monitored hosts in the same instance environment.
AVG	Stores the average value of the performance data for the monitored hosts in the same instance environment.
COPY	Stores the value of specific performance data in all the performance data for the monitored hosts in the same instance environment.
FIXED	Stores a specific value regardless of the performance data.

List of data types

The table below lists the data types of the field values, together with their corresponding C and C++ data types. The values shown in the *Field* column under *Data type* are those shown in the *Format* column of the record field tables.

Table 7–6: List of data types

Data type		Size (bytes)	Description
Field	C and C++		
char (<i>n</i>)	char ()	1	Character data (from 0x20 to 0x7e)
double	double	8	Numeric value (1.7E±308 (15 digits))
long	long	4	Numeric value (from -2,147,483,648 to 2,147,483,647)
short	short	2	Numeric value (from -32,768 to 32,767)
string (<i>n</i>)	char[]	Value in parentheses	Character string with a length of <i>n</i> bytes. The last character is the null.
time_t	unsigned long	4	Numeric value (from 0 to 4,294,967,295)
timeval	struct	8	Numeric value (the first 4 bytes are the seconds, the next 4 bytes are the microseconds)
ulong	unsigned long	4	Numeric value (from 0 to 4,294,967,295)
ushort	unsigned short	2	Numeric value (from 0 to 65,535)
utime	struct	8	Numeric value (the first 4 bytes are the seconds, the next 4 bytes are the microseconds)
word	unsigned short	2	Numeric value (from 0 to 65,535)
(Not applicable)	unsigned char	1	Numeric value (from 0 to 255)

Field values

This section describes the values stored in the fields.

For details about the source of data to be stored in the individual fields and the computation method (data sources), see *J. Data Sources of Records*.

Delta

In contrast to data collected as a cumulative value, a so-called *delta* value is data that indicates the amount by which the collection value has changed. For example, if the performance data value obtained during the first collection was 3 and the performance data value obtained during the second collection is 4, then the cumulative value is 7 but the change in the collected value is 1. In the tables, the *Delta* column indicates whether each field's value is a delta value. The performance data collected by PFM - RM for Platform varies as shown in the table below.

Note that the delta value can be a negative because it is a value relative to the previous data.

Table 7–7: Performance data collected by PFM - RM for Platform

Record type	Delta	Performance data referencing method	Indicate delta value [#]	Performance data value
PI record type	Yes	• Real-time report	Selected	The displayed value is the change amount.
			Not selected	The displayed value is the change amount.
		• Historical report • Alarm evaluation	--	The displayed value is the change amount.
	No	• Real-time report	Selected	The displayed value is the actual value at the time of data collection.
			Not selected	The displayed value is the actual value at the time of data collection.
		• Historical report • Alarm evaluation	--	The displayed value is the actual value at the time of data collection.
PD record type	Yes	• Real-time report	Selected	The displayed value is the change amount.
			Not selected	The displayed value is the cumulative value.
		• Historical report • Alarm evaluation	--	The displayed value is the cumulative value.
	No	• Real-time report	Selected	The displayed value is the actual value at the time of data collection.
			Not selected	The displayed value is the actual value at the time of data collection.
		• Historical report • Alarm evaluation	--	The displayed value is the actual value at the time of data collection.

Legend:

--: Not applicable because the item is not displayed.

#

Indicates whether one of the following items is selected in the check boxes for real-time report settings in PFM - Web Console:

- **Indicate delta value** in the report wizard's Edit > Indication Settings(Realtime) window
- **Indicate delta value** in **Indication Settings(Realtime)** on the **Properties** page in the Report window.

Notes about performance data collection

The following notes apply to collection of performance data:

- For a record of the PI record type to be stored, performance data must be collected at least twice.
For the records of the PI record type, performance data is collected at the interval set by PFM - Web Console. However, no collected performance data is stored in the Store database at the time the performance data collection setting is executed in PFM - Web Console.
Because historical data for records of the PI record type contains data (delta value) that requires a difference from the previously collected data, data obtained by two collections is required. Therefore, a maximum of twice the set time is required before historical data can be stored in the Store database.
For example, if 300 seconds (5 minutes) is set as the performance data collection interval at 18:32 in PFM - Web Console, the first data collection will begin at 18:35. The next data collection will begin at 18:40. Historical data will be created from the data collected at 18:35 and 18:40; this historical data will be stored in the Store database at 18:40 (8 minutes after 18:32 when the settings were specified).
- In real-time reports, values are displayed from the first time data is collected. If a report requires initial data, 0 will be displayed as the initial value. For the second and subsequent data collections, the operation depends on the report.
- In the following cases, the value of the collected data is displayed after the second data collection:
 - **Indicate delta value** is not selected in the real-time report settings for records of the PI record type.
 - **Indicate delta value** is selected in the real-time report settings for records of the PD record type.
- In the following case, the difference between the first and second data is displayed at the time of the second data collection, and the value of the collected data is displayed at the time of the third and subsequent collections:
 - **Indicate delta value** is selected in the real-time report settings for records of the PI record type.
- If the monitoring target's channel is restarted when PFM - RM for Platform starts, the value of collected data might become negative. For the second and subsequent data that is collected, a positive value will be displayed as the difference between the data.

Fields that are added only when a record is recorded in the Store database

The following table lists the fields that are added only when data is recorded in the Store database.

Table 7–8: Fields that are added only when a record is recorded in the Store database

PFM - View name (PFM - Manager name)	Description	Format	Delta	Supported version
Agent Host (DEVICEID)	Identifier including the name of the host where PFM - RM for Platform is running	string (256)	No	All
Agent Instance (PROD_INST)	Instance name of PFM - RM for Platform	string (256)	No	All
Agent Type (PRODID)	Product ID of PFM - RM for Platform, expressed as a 1-byte identifier	char	No	All
Date (DATE)	Record creation date, in GMT (Greenwich Mean Time) ^{#1, #2}	char (3)	No	All
Date and Time (DATETIME)	Combination of the Date (DATE) and Time (TIME) fields ^{#2}	char (6)	No	All
Drawer Type (DRAWER_TYPE)	For a record of the PI record type, the data summarization type.	char	No	All
GMT Offset (GMT_ADJUST)	Difference (in seconds) between Greenwich Mean Time and local time	long	No	All
Time (TIME)	Record creation time in GMT (Greenwich Mean Time) ^{#1, #2}	char (3)	No	All

#1

A relative time during summarization is set because data is summarized for records of the PI record type. The following table shows the setting for each record type:

Table 7–9: Setting for each record type

Type	Setting for each record type
Minute	At the 0 second of the time when the record was created.
Hour	At the 0 minute and 0 second of the time when the record was created.
Day	At 00:00:00 of the day when the record was created.
Week	At 00:00:00 on Monday of the week when the record was created.
Month	At 00:00:00 on the first of the month when the record was created.
Year	At 00:00:00 on January 1st of the year when the record was created.

#2

When data is displayed in reports, the Date field is displayed in the format *YYYYMMDD*, the Date and Time field is displayed in the format *YYYYMMDD hh:mm:ss*, and the Time field is displayed in the format *hh:mm:ss*.

Notes on records

This section provides notes about record collection.

Notes about preparing for collection of performance data

The following point should be noted before you collect performance data:

Changing registry

This note is applicable to Windows.

PFM - RM for Platform supports operation in an environment that is set up by the OS-provided standard method.

If you use special OS settings, such as by using a registry editor to directly edit registry information, performance data might not be collected correctly even if such customization is disclosed in the Microsoft technical support information.

Collecting historical data

For each record, PFM - RM for Platform stores historical data for all monitoring targets in an instance, or historical data summarized for each group agent, in the same data file. The maximum size limit for each data file is 2 gigabytes. Therefore, if an instance contains many monitoring targets or if a record contains many instances, it might not be possible to store all of the historical data in the Store database.

Of all the data collected, the historical data summarized for each group agent might cause a data file space shortage. Therefore, when using a group agent for monitoring, we recommend that you use real-time monitoring rather than monitoring based on historical data.

If you monitor based on history, you need to reduce the number of monitoring targets in the instance to prevent the data file size from exceeding 2 gigabytes, or use the LOGIF property to reduce the amount of data that is to be stored in the Store database.

For details about how to estimate the disk space that the Store database will occupy, see [A. Estimating System Requirements](#).

Notes about identifying record instances

The following note is about identifying record instances.

When instances are not identified uniquely

This note applies only when the monitored host is running Windows.

PFM - RM for Platform collects performance data by referencing the most recent information at specific intervals.

If PFM - RM for Platform cannot identify the record instance uniquely from the information acquired from the OS, it adds a number in the format #*n* (*n*: 1, 2, 3, ...) at the end of the following field:

Record name	Field name
Network Interface Overview (PI_NET)	Interface (INTERFACE)

Notes about changing the system resources for the monitored host

The following note concerns changing the system resources for the monitored host.

Performance data before and after system resources are changed

When you change system resources for the monitored host, continuity between the performance data collected before and after the change is lost. Therefore, the performance data before and after the change must be handled as different sets of performance data.

Notes about records

Data values in a record whose instance name is `_Total`

The total and average values of all instances are collected as data values in the record whose instance name is indicated as `_Total` among all multi-instance records. If the instance environment is changed during the collection interval, values might not match.

Value exceeding the data type defined in the data model

PFM - RM for Platform does not support a value that is outside the permissible range for the data type defined in the data model. If a value exceeding the data type defined in the data model is collected, the values that are displayed might not be accurate.

When records are not created

If PFM - RM for Platform cannot collect the performance data for the field that is defined as the ODBC key field, no record is created.

Fields for which performance data is not collected during the first collection

Non-PD records contain fields for which performance data is not collected during the first collection. For these fields, performance data is collected during the second and subsequent collections.

When accurate performance data cannot be collected because of an action specific to the virtualization facility

You might not be able to collect accurate performance data due to an action specific to the virtualization facility, such as a time jump.

When accurate performance data cannot be collected from an AIX monitored host

If the instance settings of PFM - RM for Platform satisfy all of the following conditions, you might not be able to collect accurate performance information:

- An AIX host is set for the monitored host.
- The `iostat` kernel parameter of the monitored host is set to `false`.
- The `sar` command was executed on the monitored host.
- The `Std_Category` or `Disk_Category` property of the instance is set to `Y`.

When PFM - Agent for Platform is running on the monitored host, you might not be able to collect accurate performance information if the instance settings satisfy all of the following conditions:

- An AIX host is set for the monitored host.
- The `iostat` kernel parameter of the monitored host is set to `false`.
- The `Agent Configuration - sar Command Monitoring` property of PFM - Agent for Platform running on the monitored host is set to `Y`.
- The `Std_Category` or `Disk_Category` property of the instance is set to `Y`.

If the `Std_Category` property is set to `Y`, you might not be able to collect CPU-related performance information.

If the `Disk_Category` property is set to `Y`, you might not be able to collect disk-related performance information.

When accurate performance data cannot be collected because of a change in the disk device

If the disk device indicated by the disk device name is changed by a change to the system, for example, continuity is lost in the performance information captured after the change to the system, even if the disk device name remains the same.

When accurate performance data cannot be collected because of the state of the mounted remote file system

Only operate PFM - RM for Platform when the information in the mounted remote file system can be referenced (the state in which the `df` command can be executed normally). If the `Disk_Category` property of the instance is set to `Y` while the mounted remote file system is not responding, the Remote Agent service cannot collect correct

performance data. For details about how to recover from this state, see [9.2.3 PFM - RM for Platform was started, but no performance data is being collected](#).

List of records

The following table lists and describes the records that can be collected by PFM - RM for Platform and the information that is stored in each record.

Table 7–10: List of records

Category	Record name	Record ID	Information stored in record
Process	Application Process Count	PD_APPC	Performance data that summarizes, at a given point in time, the records stored in the Application Process Overview (PD_APS) and Application Service Overview (PD_ASVC) records for each of the processes and services being monitored on a per-application basis
	Application Process Detail	PD_APPD	Performance data that summarizes, at a given point in time, the records stored in the Application Process Overview (PD_APS) and Application Service Overview (PD_ASVC) records for each of the processes and services being monitored on a per-application basis. Provides more detailed performance data than the Application Process Count (PD_APPC) record.
	Application Process Overview	PD_APS	Performance data indicating the status of a process of the monitored host at a given point in time
	Application Service Overview	PD_ASVC	Performance data indicating the status, at a given point in time, of an application service such as the Win32 process registered in the service control manager (SCM) of the monitored host
	Application Summary	PD_APP2	Performance data that summarizes, at a given point in time, the records stored in the Application Process Overview (PD_APS) and Application Service Overview (PD_ASVC) records on a per-application basis
Disk	Logical Disk Overview	PI_LDSK	Performance data, taken at a specific interval, about the capacity of a logical disk at the monitored host
	Physical Disk Overview	PI_PDSK	Performance data, taken at a specific interval, about physical disks on the monitored host
Network	Network Interface Overview	PI_NET	Performance data, taken at a specific interval, about the network interface for the monitored host
Processor	Processor Overview	PI_CPU	Performance data, taken at a specific interval, about the processors on the monitored host
System	System Status	PD	Status of the connection to the monitored host and information about the OS of the monitored host at a specific time
	System Summary	PI	Performance data, taken at a specific interval, about the processors and memory in the entire system of the monitored host

Application Process Count (PD_APPC)

Function

The Application Process Count (PD_APPC) record stores performance data that summarizes, at a given point in time, the records stored in the Application Process Overview (PD_APS) and Application Service Overview (PD_ASVC) records for each of the processes and services being monitored on a per-application basis. This record is a multi-instance record.

Notes

- Information cannot be collected if connection to the monitored host fails.
- To change the application definition, you must change the setting from PFM - Web Console.
- Information is not collected if TargetType is set to icmp in the monitoring target settings.

Default and changeable values

Item	Default value	Changeable
Sync Collection With	Detail Records , APP2	N
Log	No	Y
LOGIF	(Blank)	Y
Over 10 Sec Collection Time	No	N
Realtime Report Data Collection Mode	Reschedule	Y

Legend:

Y: Changeable

N: Not changeable

ODBC key field

PD_APPC_APPLICATION_NAME

PD_APPC_MONITORING_NUMBER

Lifetime

From the time a condition is added in PFM - Web Console until the time the condition is deleted

Record size

- Fixed part: 1,034 bytes
- Variable part: 135 bytes

Fields

PFM - View name (PFM - Manager name)	Description	Smry rule	Grpg rule	Format	Delta	Not sprtd on
Record Type (INPUT_RECORD_TYPE)	Record name. Always APPC	--	COPY	char (8)	No	--
Record Time (RECORD_TIME)	Time when the record was created	--	COPY	time_t	No	--

PFM - View name (PFM - Manager name)	Description	Smry rule	Grpg rule	Format	Delta	Not sprtd on
Interval (INTERVAL)	Always 0	--	FIXED	ulong	No	--
VA DeviceID (VADEVICEID)	Device ID of the monitored host	--	COPY	string (256)	No	--
Target Host (TARGET_HOST)	Monitored host name	--	FIXED	string (33)	No	--
Polling Time (POLLING_TIME)	Time the performance information was collected on the PFM - RM host	--	FIXED	string (32)	No	--
Target Host Time (TARGET_HOST_TIME)	Time the performance information was collected on the monitored host	--	FIXED	string (32)	No	--
Application Name (APPLICATION_NAME)	Application definition name specified during process monitoring setup	--	COPY	string (64)	No	--
Monitoring Number (MONITORING_NUMBER)	Monitoring condition number	--	COPY	word	No	--
Monitoring Label (MONITORING_LABEL)	Name for identifying a specific monitoring condition	--	FIXED	string (32)	No	--
Monitoring Min (MONITORING_MIN)	Minimum monitoring count	--	ADD	ulong	No	--
Monitoring Max (MONITORING_MAX)	Maximum monitoring count	--	ADD	ulong	No	--
Monitoring Count (MONITORING_COUNT)	Number of running processes and services that match the monitoring condition	--	ADD	ulong	No	--
Monitoring Status (MONITORING_STATUS)	Conditional result of the monitoring count NORMAL: No problem ABNORMAL: Abnormal	--	FIXED	string (9)	No	--
Ext1 (EXT1) [#]	Extension field 1	--	AVG	double	No	All
Ext2 (EXT2) [#]	Extension field 2	--	AVG	double	No	All

Legend:

--: Supported on all OSs of the monitored hosts (or there is no applicable summary rule).

All: Not supported on any OS of the monitored hosts.

Smry rule: Summary rule

Grpg rule: Grouping rule

Not sprtd on: Not supported on

[#]

This field is not used for operations.

Application Process Detail (PD_APPD)

Function

The Application Process Detail (PD_APPD) record stores performance data that summarizes, at a given point in time, the records stored in the Application Process Overview (PD_APS) and Application Service Overview (PD_ASVC) records for each of the processes and services being monitored on a per-application basis. Provides more detailed performance data than the Application Process Count (PD_APPC) record. This record is a multi-instance record.

Notes

- Information cannot be collected if connection to the monitored host fails.
- To change the application definition, you must change the setting from PFM - Web Console.
- This record can be used in real-time reports only. If you try to display this record in a historical report, the error KAVJS5001-I occurs.
- Information is not collected if TargetType is set to icmp in the monitoring target settings.

#

This field is not used for operations.

Application Process Overview (PD_APS)

Function

The Application Process Overview (PD_APS) record stores performance data indicating the status of a process of the monitored host at a given point in time. This record is a multi-instance record.

Notes

- Information cannot be collected if connection to the monitored host fails.
- Each process indicates a program being executed during collection.
- This record can be used in real-time reports only. If you try to display this record in a historical report, the error KAVJS5001-I occurs.
- Any character in the information to be acquired that is not in the ASCII character set range of 0x20 to 0x7E will be converted to a hash mark (#: 0x23) before it is stored in the Program Name (PROGRAM_NAME), Command Line (COMMAND_LINE), and Virtual Env ID (VIRTUAL_ENV_ID) fields. Note that multi-byte characters are processed in single-byte units during conversion. For example, the multi-byte (full-width) letter **A** is converted as follows:

Information to be acquired		Information after conversion	
Character encoding	Binary	Binary	Character string
Shift-JIS	8260	2360	#`
EUC	A3C1	2323	##
UTF-8	EFBCA1	232323	###

- The value in the Command Line (COMMAND_LINE) field might end in a space. Therefore, when defining a conditional expression for alarms or specifying the collection of process operation status information, note whether the value ends in a space.
- When the OS of the monitored host is Windows, the value in the Program Name (PROGRAM_NAME) field corresponds to the value displayed in the **Image Name** column when the **Processes** tab of Windows Task Manager is clicked.
- When the OS of the monitored host is Windows, the entire value in the Command Line (COMMAND_LINE) field might be enclosed in double quotation marks ("). When using the value in the Command Line (COMMAND_LINE) field to define a conditional expression for alarm, you must replace the double quotation marks (") with single-byte asterisks (*). For details about how to define a conditional expression for alarms, see the chapter that describes operation monitoring using an alarm in the *JPI/Performance Management User's Guide*.
- When the OS of the monitored host is a UNIX environment, the values in the Program Name (PROGRAM_NAME) and Command Line (COMMAND_LINE) fields correspond to the values displayed in the COMMAND column when the following ps command is executed with C specified in the LANG environment variable:
 - In AIX: `ps -A -X -o comm, args`
 - In HP-UX: `UNIX95=1 ps -A -o comm, args`
 - In Linux: `ps -e -o comm, args`
 - In Solaris: `ps -e -o fname, args`

The first COMMAND column is stored in the Program Name (PROGRAM_NAME) field and the second COMMAND column is stored in the Command Line (COMMAND_LINE) field. Note that the value displayed in COMMAND column differs depending on the OS.

- When the OS of the monitored host is a UNIX environment, the value in the Terminal (TERMINAL) field corresponds to the value displayed in the TTY (TT) column when the ps command is executed. The displayed value differs depending on the OS.
- When the OS of the monitored host is a UNIX environment, the Virtual Env ID (VIRTUAL_ENV_ID) field displays a value only if the OS of the monitored host is AIX6.1 or later or Solaris10 or later. Nothing is displayed for other OSs.
- When the OS of the monitored host is a UNIX environment, n/a is displayed in the Terminal (TERMINAL) field for zombie processes.
- When the OS of the monitored host is the Workload Partition (WPAR) environment of AIX V6.1 or later, the Virtual Env ID (VIRTUAL_ENV_ID) field displays Global or global.
- Information is not collected if TargetType is set to icmp in the monitoring target settings.

[#]

This field is not used for operations.

Application Service Overview (PD_ASVC)

Function

The Application Service Overview (PD_ASVC) record stores performance data indicating the status, at a given point in time, of an application service such as the Win32 process registered in the service control manager (SCM) of the monitored host. This record is a multi-instance record.

Notes

- Information cannot be collected if connection to the monitored host fails.
- This record is not created when the OS of the monitored host is UNIX.
- This record can be used in real-time reports only. If you try to display this record in a historical report, the error KAVJS5001-I occurs.
- Any character in the information to be acquired that is not in the ASCII character set range of 0x20 to 0x7E will be converted to a hash mark (#; 0x23) before it is stored in the Service Name (SERVICE_NAME) and Display Name (DISPLAY_NAME) fields. Note that multi-byte characters are processed in single-byte units during conversion. For example, the multi-byte (full-width) letter A is converted as follows:

Information to be acquired		Information after conversion	
Character encoding	Binary	Binary	Character string
Shift-JIS	8260	2360	# `
EUC	A3C1	2323	##
UTF-8	EFBCA1	232323	###

- The value in the Service Name (SERVICE_NAME) field corresponds to the value displayed in **Service Name** when a service property is opened in the service control manager (SCM).
- The value in the Display Name (DISPLAY_NAME) field corresponds to the value displayed in **Displayed Service Name** when a service property is opened in the service control manager (SCM).
- Information is not collected if TargetType is set to icmp in the monitoring target settings.

Application Summary (PD_APP2)

Function

Application Summary (PD_APP2) record stores performance data that summarizes, at a given point in time, the information stored in the Application Process Overview (PD_APS) and Application Service Overview (PD_ASVC) records on a per-application basis. This record is a multi-instance record.

Notes

- Information cannot be collected if connection to the monitored host fails.
- To change the application definition, you must change the setting from PFM - Web Console.
- Information is not collected if `TargetType` is set to `icmp` in the monitoring target settings.

Logical Disk Overview (PI_LDSK)

Function

The Logical Disk Overview (PI_LDSK) record stores performance data, taken at a specific interval, about the capacity of a logical disk at the monitored host. This is a multi-instance record.

Notes

- If the connection to the monitored host fails, the information cannot be collected.
- If you collect this record in a Windows environment, note the following:
 - This record collects performance information for hard disk drives and fixed disk drives. Performance information for other devices (such as network disks) cannot be monitored.
 - If a disk volume corresponding to the ID (ID) field is not accessible due to the security settings, no record for that disk volume is created. To create a record for such a disk volume, change the security settings so that the user account specified for User in the monitoring target settings can be used to access the disk volume.
 - If no drive letter or drive path is assigned to the disk volume, 0 is set in the Size (SIZE) field.
 - If multiple drive letters or drive paths are assigned to the same disk volume, 0 might be set in the Size (SIZE) field.
 - If you change the drive letter or drive path of a disk volume, restart the WMI service of the monitoring target you changed. If you try to collect records without restarting it, you might not be able to collect the records from that disk volume. Even if the record is collected, the Size (SIZE) field might contain a value of 0 and the ID (ID) field might contain the logical disk volume name before the change was made.
- If the OS of the monitored host is UNIX, and if Filesystem or Mounted on includes a space when you execute the df command on the monitored host, the Logical Disk Overview (PI_LDSK) record will not be correctly displayed.
- If the monitored host uses an optical drive, the Free Mbytes % field for the applicable instance is sometimes set to 0% when media is inserted into the drive. To remove the Free Mbytes % field from the alarm settings, specify ID <> applicable-disk in the alarm condition expression.
- Information is not collected if TargetType is set to icmp in the monitoring target settings.

Network Interface Overview (PI_NET)

Function

The Network Interface Overview (PI_NET) record stores performance data, taken at a specific interval, about the network interface for the monitored host. This is a multi-instance record.

Notes

- If the connection to the monitored host fails, the information cannot be collected.
- If the OS of the monitored host is Windows, Solaris, AIX, or Linux, and if this record is collected in an environment where IPv4 and IPv6 coexist, summarized information for both IPv4 and IPv6 is collected.
- If the OS of the monitored host is HP-UX, and if this record is collected in an environment where IPv4 and IPv6 coexist, information is collected separately for IPv4 and IPv6. In an IPv4 environment, IPv4 : is attached to the beginning of the ID, while in an IPv6 environment, IPv6 : is attached to the beginning of the ID.
- Information is not collected if TargetType is set to icmp in the monitoring target settings.

Physical Disk Overview (PI_PDSK)

Function

The Physical Disk Overview (PI_PDSK) record stores performance data, taken at a specific interval, about physical disks on the monitored host. This is a multi-instance record.

Notes

- If the connection to the monitored host fails, the information cannot be collected.
- Note the following points when collecting this record in a Windows environment:
 - If a security setting prevents access to the disk volume that corresponds to the ID (ID) field, no record is created for this disk volume. To create a record of the disk volume, set the security setting in the monitoring target setup to allow the user account specified in User to access the disk volume.
 - If you change the drive letter or drive path of a disk volume, restart the WMI service of the monitoring target you changed. If you try to collect records without restarting it, you might not be able to collect the records from that disk volume. Even if a record is collected, the ID (ID) field might display the disk volume name before the change was made.
- If the OS of the monitored host is AIX, only the following users can collect this record information:
 - root user
 - User who belongs to both adm and system groups
- If the OS of the monitored host is AIX, and if you change the device name by using a command such as `rendev`, performance data is collected for a different instance than the one that was present before the change.
- If the OS of the monitored host is the Workload Partition (WPAR) environment of AIX V6.1 or later, the information for this record cannot be collected.
- Information is not collected if TargetType is set to icmp in the monitoring target settings.

Processor Overview (PI_CPU)

Function

The Processor Overview (PI_CPU) record stores performance data, taken at a specific interval, about the processors on the monitored host. This is a multi-instance record.

Notes

- If the connection to the monitored host fails, the information cannot be collected.
- If this record is collected in a Windows environment, 100 is set as the maximum value of the following fields whose ID (ID) field is `_Total`:
 - CPU % (CPU_PERCENT)
 - System % (SYSTEM_PERCENT)
 - User % (USER_PERCENT)
- If the OS of both the PFM - RM host and the monitored host is 64-bit Windows, you can collect a maximum of 32 pieces of CPU information.
- If the OS of the monitored host is AIX and a user other than the root user is collecting information, 0 is displayed in the following fields if that user does not belong to either the `adm` group or `system` group:
 - CPU % (CPU_PERCENT)
 - Idle % (IDLE_PERCENT)
 - System % (SYSTEM_PERCENT)
 - User % (USER_PERCENT)
 - Wait % (WAIT_PERCENT)
 - Ext1 (EXT1)
 - Ext2 (EXT2)
- If the OS of the monitored host is the Workload Partition (WPAR) environment of AIX V6.1 or later, 0 is displayed in the following fields:
 - CPU % (CPU_PERCENT)
 - Idle % (IDLE_PERCENT)
 - System % (SYSTEM_PERCENT)
 - User % (USER_PERCENT)
 - Wait % (WAIT_PERCENT)
 - Ext1 (EXT1)
 - Ext2 (EXT2)
- Information is not collected if `TargetType` is set to `icmp` in the monitoring target settings.

System Status (PD)

Function

The System Status (PD) record stores the status of the connection to the monitored host and information about the OS of the monitored host at a specific time.

Notes

- If the connection to the monitored host fails, information is collected only in the following fields:
 - Record Type (INPUT_RECORD_TYPE)
 - Record Time (RECORD_TIME)
 - Interval (INTERVAL)
 - VA DeviceID (VADEVICEID)
 - Target Host (TARGET_HOST)
 - Polling Time (POLLING_TIME)
 - Status (STATUS)
 - Reason (REASON)
- Information is not collected if TargetType is set to icmp in the monitoring target settings.

This field is not used for operations.

System Summary (PI)

Function

The System Summary (PI) record stores performance data, taken at a specific interval, about the processors and memory in the entire system of the monitored host.

Note

- If the connection to the monitored host fails, the information cannot be collected.
- If the OS of both the PFM - RM host and the monitored host is 64-bit Windows, you can collect a maximum of 32 pieces of CPU information.
- There is no upper limit to the number of instances you can create. The maximum number of monitoring targets you can create per instance is 50.
- If the OS of both the monitored hosts is HP-UX, AIX, or Linux, the memory size allocated as the file cache is treated as the size of used physical memory area in the following fields:
 - Free Mem % (FREE_MEM_PERCENT)
 - Free Mem Mbytes (FREE_MEM_MBYTES)
 - Used Mem % (USED_MEM_PERCENT)
 - Used Mem Mbytes (USED_MEM_MBYTES)
- If the OS of the monitored host is AIX and a user other than the root user is collecting information, 0 is displayed in the following fields if that user does not belong to either the `adm` group or `system` group:
 - CPU % (CPU_PERCENT)
 - Idle % (IDLE_PERCENT)
 - System % (SYSTEM_PERCENT)
 - User % (USER_PERCENT)
 - Wait % (WAIT_PERCENT)
 - Free Swap % (FREE_SWAP_PERCENT)
 - Free Swap Mbytes (FREE_SWAP_MBYTES)
 - Used Swap % (USED_SWAP_PERCENT)
 - Used Swap Mbytes (USED_SWAP_MBYTES)
 - Total Swap Mbytes (TOTAL_SWAP_MBYTES)
 - Page Fault Counts/sec (PAGE_FAULT_COUNTS_PER_SEC)
- If the OS of the monitored host is the Workload Partition (WPAR) environment of AIX V6.1 or later, 0 is displayed in the following fields:
 - CPU % (CPU_PERCENT)
 - Idle % (IDLE_PERCENT)
 - System % (SYSTEM_PERCENT)
 - User % (USER_PERCENT)
 - Wait % (WAIT_PERCENT)
 - Free Mem % (FREE_MEM_PERCENT)

- Free Mem Mbytes (FREE_MEM_MBYTES)
- Used Mem % (USED_MEM_PERCENT)
- Used Mem Mbytes (USED_MEM_MBYTES)
- Total Mem Mbytes (TOTAL_MEM_MBYTES)
- Free Swap % (FREE_SWAP_PERCENT)
- Free Swap Mbytes (FREE_SWAP_MBYTES)
- Used Swap % (USED_SWAP_PERCENT)
- Used Swap Mbytes (USED_SWAP_MBYTES)
- Total Swap Mbytes (TOTAL_SWAP_MBYTES)
- Page Fault Counts/sec (PAGE_FAULT_COUNTS_PER_SEC)
- Information is not collected if TargetType is set to icmp in the monitoring target settings.

Messages

This chapter describes the format of the PFM - RM for Platform messages, lists the destinations to which messages are output, shows which messages are output to the Windows event log and syslog, and describes the messages in detail.

8.1 Message format

This section explains the format of messages issued by PFM - RM for Platform. It also describes the notations used in this manual to explain the messages.

8.1.1 Format of output messages

This section explains the format of the messages issued by PFM - RM for Platform.

Each message consists of a message ID, followed by a message text. The message format is as follows:

`KAVLnnnnn-Y message-text`

The message ID is composed of the following elements:

K

Identifier of the system.

AVL

Indicates a PFM - RM for Platform message.

nnnnn

Message number. The message numbers for PFM - RM for Platform are in the 17,000 series (17xxx).

Y

Type of message:

- **E: Error**
The processing has been cancelled.
- **W: Warning**
The processing resumes after the message has been output.
- **I: Information**
The system is providing the user with information.
- **Q: Query**
The system is prompting the user to enter a response.

The following are the correspondences between the message type and the Windows event log type:

-E

- Level: Error
- Description: Error message

-W

- Level: Warning
- Description: Warning message

-I

- Level: Information
- Description: Additional information message

-Q

(Not output)

The following are the correspondences between the message type and the syslog priority level:

-E

- Level: LOG_ERR
- Description: Error message

-W

- Level: LOG_WARNING
- Description: Warning message

-I

- Level: LOG_INFO
- Description: Additional information message

-Q

(Not output)

8.1.2 Format of message explanations

This section describes the format used to explain messages in this manual.

The part of a message text that is shown in *italics* represents a variable; the actual wording in the message will depend on the circumstances. The manual lists the messages in the order of the message IDs. The following illustrates the format of a message explanation:

message-ID

message-text

Explanation of the message

S:

Explains the processing performed by the system.

O:

Explains the action the operator should take when the message is displayed.

Note

When the system administrator is contacted by the operator, the system administrator should collect log information and conduct initial checking in accordance with the procedures explained in [9. Error Handling Procedures](#).

When you conduct initial checking to determine the cause of a problem, examine all applicable log information, such as the log information for the OS (Windows event log or syslog) and the log information output by PFM - RM for Platform. The log information enables you to understand the details of the processing that was underway when the problem occurred and to take appropriate action. You

should also make a record of the operations that led up to the problem and evaluate whether the problem is likely to recur.

8.2 Message output destinations

This section shows the output destinations of the messages issued by PFM - RM for Platform.

Whether a message is output to a destination shown in the table below is indicated by *Y* or *--*:

Legend:

Y: Message is output to the destination.

--: Message is not output to the destination.

Win. event log: Windows event log

stdout: Standard output

stderr: Standard error

Table 8–1: PFM - RM for Platform message output destinations

#1

A JP1 system event notifies JP1/IM of a change in the agent status. For details about JP1 system events, see the chapter that describes the monitoring of operations linked with the integrated manager product (JP1/IM) in the *JP1/Performance Management User's Guide*.

The following table shows the programs that are required in order to issue JP1 system events.

Table 8–2: Programs required in order to issue JP1 system events

Host type	Prerequisite program	Version
PFM - Manager host	PFM - Manager	09-00 or later
PFM - Web Console host	PFM - Web Console	08-00 or later
PFM - RM host	PFM - RM for Platform	09-00 or later
	PFM - Manager or PFM - Base	09-00 or later
	JP1/Base	09-00 or later

#2

An agent event notifies PFM - Manager of a change in the agent status. For details about agent events, see the chapter that describes event display in the *JP1/Performance Management User's Guide*.

The following table shows the programs that are required in order to issue agent events.

Table 8–3: Programs required in order to issue agent events

Host type	Prerequisite program	Version
PFM - Manager host	PFM - Manager	09-00 or later
PFM - Web Console host	PFM - Web Console	08-00 or later
PFM - RM host	PFM - RM for Platform	09-00 or later
	PFM - Manager or PFM - Base	09-00 or later

8.3 List of messages output to the Windows event log and syslog

This section lists the messages that PFM - RM for Platform outputs to the Windows event log and to syslog.

If the OS is Windows, the Windows event log is displayed in the application log in the Event Viewer window.

Note

To open the Event Viewer window, from the Windows **Start** menu, choose **Administrative Tools**, and then **Event Viewer**.

For any event issued by PFM - RM for Platform, the identifier PFM-RMPlatform is displayed in the **Source** column of the Event Viewer window.

If the OS is UNIX, syslog means are output to the syslog file.

For details about the storage location of the syslog file, see the syslog daemon configuration file (default is `/etc/syslogd.conf`).

The following table lists the messages that PFM - RM for Platform outputs to the Windows event log and to syslog.

Table 8–4: Messages output to the Windows event log and syslog

Message ID	Windows event log		syslog	
	Event ID	Type	Facility	Level
KAVL17000-I	17000	Information	LOG_DAEMON	LOG_INFO
KAVL17001-E	17001	Error	LOG_DAEMON	LOG_ERR
KAVL17002-I	17002	Information	LOG_DAEMON	LOG_INFO
KAVL17003-E	17003	Error	LOG_DAEMON	LOG_ERR
KAVL17004-E	17004	Error	LOG_DAEMON	LOG_ERR
KAVL17005-E	17005	Error	LOG_DAEMON	LOG_ERR
KAVL17006-E	17006	Error	LOG_DAEMON	LOG_ERR
KAVL17007-E	17007	Error	LOG_DAEMON	LOG_ERR
KAVL17008-E	17008	Error	LOG_DAEMON	LOG_ERR
KAVL17009-E	17009	Error	LOG_DAEMON	LOG_ERR
KAVL17027-E	17027	Error	LOG_DAEMON	LOG_ERR
KAVL17028-E	17028	Error	LOG_DAEMON	LOG_ERR

8.4 Messages

This section explains the messages issued by PFM - RM for Platform and the actions to be taken.

KAVL17000-I

Remote Monitor Collector has stopped. (host=*host-name*, service=*service-ID*)

The Remote Monitor Collector service terminated normally.

S:

Terminates the Remote Monitor Collector service processing.

KAVL17001-E

Remote Monitor Collector failed to start.

Startup of the Remote Monitor Collector service failed.

S:

Terminates the Remote Monitor Collector service processing.

O:

Check the immediately preceding message that has been output to the common message log and take appropriate action according to that message.

KAVL17002-I

Remote Monitor Collector started. (host=*host-name*, service=*service-ID*)

Startup of the Remote Monitor Collector service has been completed.

S:

Starts Remote Monitor Collector's performance data collection processing.

KAVL17003-E

Remote Monitor Collector stopped abnormally.

The Remote Monitor Collector terminated abnormally.

S:

Terminates the Remote Monitor Collector service processing.

O:

Check the immediately preceding message that has been output to the common message log and take appropriate action according to that message.

KAVL17004-E

An attempt to read the service startup information file has failed.

An attempt to read the service startup initialization file failed during startup of the Remote Monitor Collector service.

S:

Terminates the Remote Monitor Collector service processing.

O:

Check whether the service startup initialization file (`jpcagt.ini`) exists under the following directory:

- In Windows:
`installation-folder\agt7\agent\instance-name\`
- In UNIX:
`/opt/jp1pc/agt7/agent/instance-name/`

KAVL17005-E

An attempt to read the target information file has failed. (Target=*monitoring-target-name*)

An attempt to read the monitoring target information file failed during startup of the Remote Monitor Collector service.

S:

Continues the Remote Monitor Collector service processing.

O:

Check for any errors with the items that were specified when the monitoring target was set up.

Check whether the monitoring target information file (*monitoring-target-name.ini*) exists under the following directory:

- In Windows:
`installation-folder\agt7\agent\instance-name\targets\`
- In UNIX:
`/opt/jp1pc/agt7/agent/instance-name/targets/`

KAVL17006-E

An error occurred in the *function-name* function. (en=*error-code*, arg1=*argument-1*, arg2=*argument-2*, arg3=*argument-3*)

An error occurred during execution of the function indicated by *function-name*.

S:

Terminates the Remote Monitor Collector service processing.

O:

Collect maintenance data and contact the system administrator. For details about how to collect maintenance data, see the chapter that describes troubleshooting in the *JP1/Performance Management User's Guide*.

KAVL17007-E

A signal interrupted processing. (signal=*signal-number*)

Processing was canceled by a signal.

S:

Terminates the Remote Monitor Collector service processing.

O:

Collect maintenance data and contact the system administrator. For details about how to collect maintenance data, see the chapter that describes troubleshooting in the *JP1/Performance Management User's Guide*.

KAVL17008-E

Remote Monitor Collector will now stop because an error occurred.

The Remote Monitor Collector service is being stopped because of an error.

S:

Terminates the Remote Monitor Collector service processing.

O:

Check the immediately preceding message that has been output to the common message log and take appropriate action according to that message.

KAVL17009-E

Memory allocation failed. (RecordType=*record-type*)

Memory allocation failed. If UNKNOWN is displayed in *record-type*, memory allocation failed for multiple record IDs.

S:

Terminates the Remote Monitor Collector service processing.

O:

Increase available memory.

KAVL17010-W

Memory allocation failed. (RecordType=*record-type*)

Memory allocation failed. If UNKNOWN is displayed in *record-type*, memory allocation failed for multiple record IDs.

S:

Resumes the Remote Monitor Collector service processing.

O:

Increase the available memory.

KAVL17011-W

An attempt to collect the record failed. (RecordType=*record-type*, Target=*monitoring-target-name*)

Acquisition of the record indicated by *record-type* failed.

S:

Resumes the Remote Monitor Collector service processing.

O:

If this message is repeatedly output at every monitoring interval for the same monitoring target and record type, check to make sure that the system environment of the monitoring target has been correctly set up. If this message is output occasionally, the machine might be overloaded. If the cause of the error cannot be determined, collect

maintenance data and contact the system administrator. For details about how to collect maintenance data, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

KAVL17012-W

An invalid value or a value outside the range was specified for the property of the Remote Monitor Collector service. (property=*property-name*, value=*value-range*, Target=*monitoring-target-name*)

An invalid value or a value outside the permitted range was specified for the indicated property of the Remote Monitor Collector service.

S:

Ignores the specified value and resumes the Remote Monitor Collector service processing. The value of this item remains unchanged.

O:

Check to see if the set value causes problems. If the value is not appropriate, specify an appropriate value.

KAVL17013-W

The collector process failed to start.

Startup of the collection process failed.

S:

Resumes the Remote Monitor Collector service processing.

O:

Collect maintenance data and contact the system administrator. For details about how to collect maintenance data, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

KAVL17014-W

The collector process stopped abnormally.

The collection process terminated abnormally.

S:

Resumes the Remote Monitor Collector service processing.

O:

If this message is output more than once in succession, check the monitoring target's system environment settings for any error. If the cause of the error cannot be determined, collect maintenance data and contact the system administrator. For details about how to collect maintenance data, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

KAVL17015-W

A performance data file is invalid. (Target=*monitoring-target-name*)

The contents of the performance data storage file are invalid.

S:

Resumes the Remote Monitor Collector service processing.

O:

Collect maintenance data and contact the system administrator. For details about how to collect maintenance data, see the chapter that describes troubleshooting in the *JP1/Performance Management User's Guide*.

KAVL17016-W

Performance data was not saved to the Store database because it is the same as previous performance data.
(RecordType=*record-type*, Target=*monitoring-target-name*)

The performance data was not saved in the Store database because it was the same as the previous data.

S:

Resumes the Remote Monitor Collector service processing.

O:

- Specify the record collection interval or the collection interval for the collection process in such a manner that the following condition is satisfied: record collection interval \geq collection interval for the collection process.
If the condition record collection interval \geq collection interval for the collection process is satisfied but this warning occurs frequently, either increase the collection interval or reduce the number of monitored hosts in the instance environment.
- Set the collection interval for the collection process (Interval setting value for the instance environment) and the collection interval for each performance data (Collection Interval setting value for each record) to the amount of time it takes to complete the collection of performance data from all monitored hosts in the instance.

For details, see [9.2.5 The message "KAVL17016-W Performance data was not saved to the Store database because it is the same as previous performance data." is output to the common message log](#).

KAVL17017-W

The record build failed because there is no performance data. (Target=*monitoring-target-name*)

Record creation failed because there was no performance data.

S:

Resumes the Remote Monitor Collector service processing.

O:

This warning might occur immediately after startup because there is no performance data yet. If this warning continues to occur even after some time has elapsed after startup, check the following items for each OS of the monitored hosts:

If the monitored host is running Windows

- Is the monitored host running?
- Is the WMI service running on the monitored host?
- Were the following settings specified correctly when the monitoring target was set up?
 - TargetHost
 - UseCommonAccount
 - User
 - Password
 - Domain

If you are using common account information, check for any errors with the following items specified in common account information (wmi):

- User
- Password
- Domain
- Can the name be resolved by the host name (TargetHost) specified when the monitoring target was set up?
- Was the WMI connection setting procedure performed correctly?

If the monitored host is running UNIX

- Is the monitored host running?
- Is the SSH service running on the monitored host?
- Were the following settings specified correctly when the monitoring target was set up?
 - TargetHost
 - UseCommonAccount
 - User
 - Private_Key_File
 - Port

If you are using common account information, check for any errors with the following items specified in common account information (ssh):

- User
- Private_Key_File
- Can the name be resolved by the host name (TargetHost) specified when the monitoring target was set up?
- Was the SSH connection setting procedure performed correctly?
- Were the following settings specified correctly when the instance environment was set up (only when the PFM - RM host is running in a Windows environment)?
 - SSH_Client
 - Perl_Module

If the cause of the error cannot be determined, collect maintenance data and contact the system administrator. For details about how to collect maintenance data, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

KAVL17018-I

The records were successfully saved onto the Store database. (RecordType=*record-type*, count=*records-count*, Target=*monitoring-target-name*)

The records indicated in *record-type* have been stored successfully in the Store database.

S:

Resumes the Remote Monitor Collector service processing.

KAVL17019-W

The initialization of interprocess communication failed.

Preparation for communication between the Remote Monitor Collector service and the collection process failed.

S:

Resumes the Remote Monitor Collector service processing.

O:

Processing on the work file, such as open or write processing, might have failed. Check for a shortage of available disk space.

If there is no problem with the available disk space, collect maintenance data and contact the system administrator. For details about how to collect maintenance data, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

KAVL17020-W

An error occurred during collection of the record. (Target=*monitoring-target-name*)

An error occurred during record collection.

S:

Resumes the Remote Monitor Collector service processing.

O:

Collect maintenance data and contact the system administrator. For details about how to collect maintenance data, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

KAVL17021-I

A collector process will restart because the system detected that it stopped.

The collection process will be restarted because the system detected termination of the process.

S:

Resumes the Remote Monitor Collector service processing.

KAVL17022-W

Account authentication failed.

Account authentication failed.

S:

Resumes the Remote Monitor Collector service processing.

O:

Check for any errors in the following items, which were specified during instance environment setup:

- UseCommonAccount
- RMHost_User
- RMHost_Password
- RMHost_Domain

If you are using common account information, check for any errors in the following items specified in the common account information (pfmhost):

- User
- Password
- Domain

KAVL17023-W

The user profile failed to load.

Loading of the user profile failed.

S:

Resumes the Remote Monitor Collector service processing.

O:

Check whether the following settings were specified correctly when the instance environment was set up:

- UseCommonAccount
- RMHost_User
- RMHost_Password
- RMHost_Domain

If you are using common account information, check for any errors in the following items specified in the common account information (pfmhost):

- User
- Password
- Domain

Additionally, check whether the user profile identified in the error message exists.

KAVL17024-W

There are no SSH client execution modules. (Instance=*instance-name*)

The setting of the SSH client execution module (SSH_Client) is invalid. Because the instance includes a monitored host running UNIX, specify a correct value.

S:

Resumes the Remote Monitor Collector service processing.

O:

Check whether a correct value was specified in SSH_Client when the instance environment was set up.

KAVL17025-W

There are no Perl execution modules. (Instance=*instance-name*)

The setting of the Perl execution module (Perl_Module) is invalid. Because the instance includes a monitored host running UNIX, specify a correct value.

S:

Resumes the Remote Monitor Collector service processing.

O:

Check whether a correct value was specified in `Perl_Module` when the instance environment was set up.

KAVL17026-W

There are no private keys. (Instance=*instance-name*, Target=*monitoring-target-name*)

The setting for the private key file (`Private_Key_File`) used in the SSH public key method is invalid. If the monitored host is running UNIX, specify a correct value.

S:

Resumes the Remote Monitor Collector service processing.

O:

Check for any errors in the following items that were set when the monitoring target was set up:

- `UseCommonAccount`
- `Private_Key_File`

If you are using common account information, check for any errors in the following item specified in the common account information (ssh):

- `Private_Key_File`

KAVL17027-E

Memory allocation failed.

Memory allocation failed during startup.

S:

Terminates processing the Remote Monitor Collector service.

O:

Increase the amount of free memory.

KAVL17028-E

Failed to load the common account information. (Type=*type-of-common-account-information*, Instance=*instance-name*)

An attempt to read the common account information failed during startup of the Remote Monitor Collector service.

S:

Terminates processing the Remote Monitor Collector service.

O:

Make sure that common account information has been set up.

Check for any errors in the items specified in the common account information.

After checking the above issues, use the `jpcconf acc setup` command to set up the common account information.

KAVL17029-W

Failed to load the common account information. (Type=*type-of-common-account-information*, Instance=*instance-name*)

An attempt to read the common account information failed.

S:

Continues the Remote Monitor Collector service processing.
Reads common account information again at the next collection timing.

O:

Make sure that common account information has been set up.
Check for any errors in the items specified in the common account information.
After checking the above issues, use the `jpcconf acc setup` command to set up common account information.

KAVL17030-W

Failed to add the information for the monitoring target. (Instance=*instance-name*, Target=*monitoring-target-name*)

An attempt to add monitoring target information failed.

S:

Continues the Remote Monitor Collector service processing.
Does not collect performance data for the monitoring target for which information failed to be added.

O:

Check the preceding message in the common message log, and take action according to that message.
After taking the above action, use the `jpcconf target setup` command to perform setup again.

KAVL17031-W

Failed to update the information for the monitoring target. (Instance=*instance-name*, Target=*monitoring-target-name*)

An attempt to update monitoring target information failed.

S:

Continues the Remote Monitor Collector service processing.
Collects performance data for the monitoring target based on the pre-update values.

O:

Check the preceding message in the common message log, and take action according to that message.

KAVL17032-W

Failed to load the information file for the monitoring target. (Instance=*instance-name*, Target=*monitoring-target-name*)

An attempt to read the monitoring target information file failed.

S:

Continues the Remote Monitor Collector service processing.

O:

Check for any errors in the items that were set when the monitoring target was set up.

Make sure that the monitoring target information file (*monitoring-target-name.ini*) exists in the following directory:

- For Windows
installation-folder\agt7\agent\instance-name\targets
- For UNIX
/opt/jp1pc/agt7/agent/instance-name/targets/

After checking the above issues, use the `jpccconf target setup` command to perform setup again.

KAVL17033-W

Failed to load the common start information file for the component. The instance will start as an environment that cannot use common account information. (Instance=*instance-name*)

An attempt to read the common start information file for each component failed. The system starts as an environment where common account information cannot be used.

S:

Continues the Remote Monitor Collector service processing.

O:

Make sure that the common start information file for each component (*jpccomm.ini*) exists in the following directory:

- For Windows
installation-folder
- For UNIX
/opt/jp1pc/

KAVL17034-E

An invalid setting to use common account information is set in an environment that cannot use common account information. (Instance=*instance-name*)

An environment where common account information cannot be used is set to use common account information.

S:

Terminates the Remote Monitor Collector service processing.

O:

Take one of the following actions:

- Change the setting so that common account information is not used.
- To use common account information, upgrade PFM - Manager or PFM - Base in the same device to a version that supports common account information. Then create the common account information.
- If backup data was restored, check the data at the restoration source, and restore the correct backup data.

KAVL17035-W

An invalid setting to use common account information is set in an environment that cannot use common account information. (Instance=*instance-name*, Target=*monitoring-target-name*)

An environment where common account information cannot be used is set to use common account information.

S:

Continues the Remote Monitor Collector service processing.

O:

Take one of the following actions:

- Change the setting so that common account information is not used.
- To use common account information, upgrade PFM - Manager or PFM - Base in the same device to a version that supports common account information. Then create common account information.
- If backup data was restored, check the data at the restoration source, and restore the correct backup data.

KAVL17036-W

An invalid value is set in the common account information. (Type=*type-of-common-account-information*, Label=*item-name*, value=*value-range*)

An invalid value is specified in the common account information.

S:

Continues the Remote Monitor Collector service processing by ignoring the specified value. The corresponding item retains the pre-change (original) value.

O:

Check for any errors in the items specified in the common account information.

After checking the above issue, use the `jpcconf acc setup` command to set up common account information.

9

Error Handling Procedures

This chapter describes how to handle errors that might occur while you are using Performance Management products. The focus of this chapter's discussion is on handling errors that occur in PFM - RM for Platform. For details about error handling for the entire Performance Management system, see the chapter that describes troubleshooting in the *JP1/Performance Management User's Guide*.

9.1 Error handling procedures

This section describes the procedures for handling errors that occur while you are using Performance Management products.

Checking the event

Check the following:

- Event where the error occurred
- Message contents (if a message has been displayed)
- Log information (such as the common message log)

For details about the messages and how to respond to each message, see [8. Messages](#). For details about the log information that is output by the Performance Management products, see [9.3 Log information to be collected for troubleshooting](#).

Collecting data

Collect data to determine the cause of the error. For details about how to collect the necessary data, see [9.4 Data to be collected for troubleshooting](#) and [9.5 How to collect data for troubleshooting](#).

Checking the problem

Use the collected data to check the cause of the problem. You should also isolate the problem or the affected range.

9.2 Troubleshooting

This section explains how to conduct troubleshooting while you are using Performance Management products. If an error occurs, you should first check to see if any of the events described in this section has occurred.

9.2.1 The Remote Monitor Collector service of PFM - RM does not start

If the PFM - RM host is running Windows, startup of the Remote Monitor Collector service might fail during PFM - RM startup, and one of the following messages might be displayed in the Windows event log when Windows is restarted:

- The *Service Name* service hung on starting.
- *Service Name* service hung on startup.

Because this problem is caused by a timeout in Windows service control manager, it tends to occur when PFM - Manager's communication load is high and a response from PFM - Manager takes time. This problem occurs when all of the following conditions are satisfied:

- JP1/PFM - Manager's communication load is high.
For example, many copies of PFM - RM are being started concurrently.
- In Windows **Services** applet, the startup type is set to **Automatic** for PFM - RM services.
- The OS is restarted.

To avoid this problem, take either of the following steps:

- When starting a service at the time the OS is restarted, start it by executing the `jpcspm start` command instead of starting it from Windows service control manager.
- Shorten the PFM - RM startup time by using the setting described below for the PFM - RM host.

This setting shortens the reconnection processing during startup of the PFM - RM service if PFM - Manager cannot be connected to. In this case, the probability of the PFM - RM service starting in a stand-alone mode increases.

To shorten the startup time of PFM - RM, change [Agent Collector *x* Section][#] in the startup information file (`jpccomm.ini`) and the NS Init Retry Count label of [Agent Store *x* Section][#] from NS Init Retry Count =2 to NS Init Retry Count =1.

#

The PFM - RM product ID is entered for *x*. For details about product IDs, see [B. List of Identifiers](#). If multiple copies of PFM - RM are installed on the same host, specify an NS Init Retry Count label value for each product ID.

The startup information file (`jpccomm.ini`) is stored in the following directory:

If the PFM - RM host is a physical host

`installation-folder\jpccomm.ini`

If the PFM - RM host is a logical host

`environment-directory#\jplpc\jpccomm.ini`

#

Indicates the directory on the shared disk specified when the logical host was created.

9.2.2 Failure Audit (Event ID: 4625 or 4776) is recorded in the Windows security event log.

When the monitored host is running Windows, Failure Audit (Event ID: 4625 or 4776) might be recorded in the Windows security event log.

PFM - RM for Platform makes a WMI connection to the monitored host by using the user name and password specified in the account information^{#1} when the monitoring target was set up. However, WMI also tries to connect to the monitored host by using the process-executing account information^{#2} (in which a user name and password were specified when the instance environment was set up), resulting in this problem. Even when Failure Audit (Event ID: 4625 or 4776) is displayed in the Windows security event log, there is no problem if performance information has been collected.

To avoid this problem, take the following steps:

1. Create account information having the same user name and password on the PFM - RM host and the monitored host.
2. Specify the user name and password (in the account information created in step 1) in the setting items for the instance environment and the setting items for the monitoring target as described below.
 - RMHost_User^{#2} setting item in the account information for the instance environment: *User name*
 - RMHost_Password^{#2} setting item in the account information for the instance environment: *Password*
 - User^{#1} setting item in the account information for the monitoring target: *User name*
 - Password^{#1} setting item in the account information for the monitoring target: *Password*

For details about how to specify these settings, see [3.1.4 Setup procedure for the Windows edition](#).

#1: This is a setting item (User or Password) in common account information (wmi) when common account information is used.

#2: This is a setting item (User or Password) in common account information (pfmhost) when common account information is used.

9.2.3 PFM - RM for Platform was started, but no performance data is being collected

If the Status field value in the PD record is ERROR, take appropriate action based on the Reason field value. If the cause of the error cannot be determined after you perform appropriate action, collect maintenance data and contact the system administrator.

The following describes the items to be checked for each Reason field value.

(1) Connection failed: Connection to the monitored host failed.

When the monitored host is running Windows

- Is the monitored host running?
- Is the WMI service running on the monitored host?
- Were the settings for the following specified correctly when the monitoring target was set up?^{#1}
 - TargetHost

- Can the name be resolved by the host name (`TargetHost`) that was specified when the monitoring target was set up?
- Were the following WMI connection setup procedures performed correctly?
 - DCOM setting at the PFM - RM host
 - WMI namespace setting at the monitored host
 - Firewall setting at the monitored host
- If there is a firewall between PFM - RM for Platform and the monitoring target, is the firewall passage port set appropriately?

When the monitored host is running UNIX

- Is the monitored host running?
- Is the SSH service running on the monitored host?
- Were the following settings specified correctly when the monitored host was set up?^{#1}
 - `Target Host`
 - `UseCommonAccount`^{#2}
 - `User`^{#3}
 - `Private_Key_File`^{#3}
 - `Port`
- Can the name be resolved by the host name (`TargetHost`) that was specified when the monitoring target was set up?
- Were the settings for the following items specified correctly when the instance environment was set up?^{#4} (This applies only when the PFM - RM host is running Windows.)
 - `SSH_Client`
 - `Perl_Module`
- Was the SSH connection setup procedure performed correctly?
- If there is a firewall between PFM - RM for Platform and the monitoring target, is the firewall passage port set appropriately?

#1

To check the items that have been set up, execute the `jpccconf target setup` command. If you are using common account information, execute the `jpccconf acc display` command to check the setting items. Alternatively, in PFM - Web Console, from the Remote Monitor Collector service of PFM - RM for Platform, view the Remote Monitor Configuration property to check the settings.

#2

This item is displayed when both the version of PFM - RM for Platform and the version of the prerequisite program (PFM - Manager or PFM - Base) in the same device as PFM - RM for Platform are 10-50 or later.

#3

If you are using common account information, the values of `User` and `Private_Key_File` are the respective values that are specified in `User` and `Private_Key_File` in common account information (ssh).

#4

To check the items that have been set up, execute the `jpccconf inst setup` command. Alternatively, in PFM - Web Console, from the Remote Monitor Collector service of PFM - RM for Platform, view the Remote Monitor Configuration property to check the settings.

(2) Authorization failed: Authorization of the monitored host failed.

The items to be checked in Windows are described below. This error is not applicable to UNIX.

When the monitored host is running Windows

- Were the following settings specified correctly when the monitoring target was set up?^{#1}
 - `UseCommonAccount`^{#2}
 - `User`^{#3}
 - `Password`^{#3}
 - `Domain`^{#3}
- Were the following WMI connection setup procedures performed correctly?
 - DCOM setting on the PFM - RM host
 - DCOM setting on the monitored host

#1

To check the settings, execute the `jpcconf target setup` command. If you are using common account information, execute the `jpcconf acc display` command to check the setting items. Alternatively, use PFM - Web Console to check the settings by displaying the Remote Monitor Configuration properties from the Remote Monitor Collector service of PFM - RM for Platform.

#2

This item is displayed when both the version of PFM - RM for Platform and the version of the prerequisite program (PFM - Manager or PFM - Base) in the same device as PFM - RM for Platform are 10-50 or later.

#3

If you are using common account information, the values of `User`, `Password`, and `Domain` are the respective values that are specified in `User`, `Password`, and `Domain` in common account information (wmi).

(3) Collection timeout: Performance data collection did not end within the specified time

When the monitored host is running Windows

- In the instance environment, is the collection interval of the collection process for the monitored host too short?
The collection interval of the collection process means the `Interval` setting in the instance environment. If this interval is short, either reduce the number of monitoring targets in the instance environment or lengthen the collection interval of the collection process.
- Has the monitored host been started?
- Were settings specified correctly when the monitored host was set up?^{#1}
- Was the WMI connection setting procedure followed correctly?
- Is the PFM - RM host or the monitored host under a heavy system load?

When the monitored host is running UNIX

- In the instance environment, is the collection interval of the collection process for the monitored host too short?
The collection interval of the collection process means the `Interval` setting in the instance environment. If this interval is short, either reduce the number of monitoring targets in the instance environment or lengthen the collection interval of the collection process.
- Has the monitored host been started?

- Were settings specified correctly when the monitored host was set up?^{#1}
- Was the SSH connection setting procedure followed correctly?
- Is the PFM - RM host or the monitored host under a heavy system load?
- Was `no` set for `UseDNS`^{#3} in the `/etc/ssh/sshd_config`^{#2} file on the SSH server of the monitored host?
If the environment takes time to resolve the PFM - RM for Platform host name on the SSH server of the monitored host, a timeout might occur when collecting performance data from PFM - RM for Platform. In this case, this issue might be solved by setting `no` for `UseDNS`^{#3} in the `/etc/ssh/sshd_config`^{#2} file on the SSH server of the monitored host.

#1

To check the items that have been set up, execute the `jpccconf target setup` command. Alternatively, in PFM - Web Console, from the Remote Monitor Collector service of PFM - RM for Platform, view the Remote Monitor Configuration property to check the settings.

#2

This will be `/opt/ssh/etc/sshd_config` when using HP-UX.

#3

This will be `LookupClientHostname` when using Solaris.

(4) Invalid environment (SSH_Client): The file specified in SSH_Client when the instance environment was set up does not exist (when the PFM - RM host is running Windows and the monitored host is running UNIX)

The item to be checked when the PFM - RM host is running Windows and the monitored host is running UNIX is shown below. This error is not applicable when the monitored host is running Windows or when the PFM - RM host is running UNIX.

- Was the following setting specified correctly when the instance environment was set up?[#]
`SSH_Client`

#

To check the item that has been set up, execute the `jpccconf inst setup` command. Alternatively, in PFM - Web Console, from the Remote Monitor Collector service of PFM - RM for Platform, view the Remote Monitor Configuration property to check the setting.

(5) Invalid environment (Perl_Module): The file specified in Perl_Module when the instance environment was set up does not exist (when the PFM - RM host is running Windows and the monitored host is running UNIX)

The item to be checked when the PFM - RM host is running Windows and the monitored host is running UNIX is shown below. This error is not applicable when the monitored host is running Windows or when the PFM - RM host is running UNIX.

- Was the following setting specified correctly when the instance environment was set up?[#]
`Perl_Module`

#

To check the item that has been set up, execute the `jpccconf inst setup` command. Alternatively, in PFM - Web Console, from the Remote Monitor Collector service of PFM - RM for Platform, view the Remote Monitor Configuration property to check the setting.

(6) Invalid environment (Private_Key_File): The file specified in Private_Key_File when the monitored host was set up does not exist

The environment where the message `The file specified in Private_Key_File when the monitored host was set up does not exist` is output differs according to the version of PFM - RM for Platform, as follows:

- When the version of PFM - RM for Platform is from 09-50 to 10-00: The message is output if the PFM - RM host is running Windows, and the monitored host is running UNIX.
- When the version of PFM - RM for Platform is 10-50 or later: The message is output if the PFM - RM host is running Windows or UNIX, and the monitored host is running UNIX.

The items below are checked when the monitored host is running UNIX. This error is not applicable when the monitored host is running Windows.

- Were the following items specified correctly when the monitored host was set up?^{#1}
 - `UseCommonAccount`^{#2}
 - `Private_Key_File`^{#3}

#1

To check the item that has been set up, execute the `jpccconf target setup` command. If you are using common account information, execute the `jpccconf acc display` command to check the setting items.

Alternatively, in PFM - Web Console, from the Remote Monitor Collector service of PFM - RM for Platform, view the Remote Monitor Configuration property to check the setting.

#2

This item is displayed when both the version of PFM - RM for Platform and the version of the prerequisite program (PFM - Manager or PFM - Base) in the same device as PFM - RM for Platform are 10-50 or later.

#3

If you are using common account information, the value of `Private_Key_File` is the value that is specified in `Private_Key_File` in common account information (ssh).

(7) Values other than those described above

- Collect maintenance data and contact the system administrator.
- If the monitored host is running Windows, check the application event log and take the appropriate corrective action. To use PFM - RM for Platform to collect performance data for the records listed below, PFM - RM for Platform must be set up so that objects can be monitored on the performance console.[#] The table below lists the objects corresponding to each record, the source (service) names that are output to the event log, and the performance extension DLLs.

#

You can use **Performance** to check the object name that corresponds to each record. If there is no corresponding object, specify the settings according to the procedure provided in Microsoft Knowledge Base by Microsoft so that the objects can be monitored.

Table 9–1: Objects corresponding to each record, the source (service) names that are output to the event log, and the performance extension DLLs

No.	Category	Record name (record ID)	Object name	Source (service) name that is output to the event log	Performance extension DLL
1	Disk	Logical Disk Overview (PI_LDSK)	LogicalDisk	WinMgmt	perfdisk.dll
2		Physical Disk Overview (PI_PDSK)	PhysicalDisk		
3	Network-related	Network Interface Overview (PI_NET)	Network Interface		perfctrs.dll
4	OS in general (such as processors and memory)	System Overview (PI)	Memory		perfos.dll
5			System		
6			Processor		
7		Processor Overview (PI_CPU)	Processor		

If the name `WinMgmt` is recorded in the application event log, PFM - RM for Platform might not function correctly or the records corresponding to that source (service) might not be collected. If the application event log contains the events shown in the table below, either reinstall the source (service) or eliminate the cause of the error that is disclosed in Microsoft Knowledge Base, or contact the developer of the source (service), and then repair the environment so that the application event logs are not recorded.

The following table shows examples of application event logs when PFM - RM for Platform is not functioning correctly or the records for the source (service) cannot be collected.

Table 9–2: Examples of application event logs when records are not collected successfully

No.	Event ID	Source (service) name	Event log information
1	37	WinMgmt	WMI ADAP 0x0 was unable to read the <i>file-name</i> performance library due to an unknown problem in the library.
2	41		WMI ADAP did not create object index <i>n</i> for the performance library <i>service-name</i> because the value was not found by the 009 subkey.
3	61		WMI ADAP was unable to process the <i>file-name</i> performance library due to a time violation in the open function.

- If the monitoring target is running UNIX, check whether the `df` command can be correctly executed, then take the appropriate recovery step.

If the monitoring target is running UNIX, PFM - RM for Platform needs to run in a state in which the `df` command can be executed normally and the information in the mounted remote file system can be referenced. If you specify `Y` for the setting `Disk_Category` of the instance environment when the `df` command cannot be executed normally and the remote file system does not return a response, the Remote Agent service will not be able to collect performance data correctly. In this case, take the following actions:

1. Change the setting `Disk_Category` of the instance environment to `N`.
2. Execute either of the following commands to stop the `df` process on the remote host specified as the monitoring target:
 - `kill -TERM df-process-ID`
 - `kill df-process-ID`

3. Correctly mount the remote file system by taking the appropriate action, such as restarting the NFS daemon.
4. Return the setting `Disk_Category` of the instance environment to `Y`.

9.2.4 Alarms related to process monitoring are not reported as intended

Note the following when you are monitoring the process operation status of a monitored host that is running UNIX: An error alarm might be reported even though the monitoring target process is not stopped, and then a normal alarm might be reported at the following collection time.

In a UNIX environment, when a process generates child processes, copies of these processes are created, and as a result duplicate copies of the same processes might appear to exist. Therefore, keep in mind that the number of processes increases when a process that generates child processes is the monitoring target. Specifically, an error alarm can be reported if process information is collected at the time the number of processes increases, and a normal alarm can then be reported if process information is collected at the time the number of processes returns to 1.

To avoid this phenomenon, take the following steps:

- If the maximum number of concurrently existing child processes that will be generated by the monitoring target process is clear, specify the result of the formula shown below for the upper threshold of the number of monitoring target processes. Here, m indicates the maximum number of active processes and n indicates the maximum number of concurrently existing child processes per process.

$$m \times (1 + n)$$

If the calculation result exceeds 65,535, specify 65535.

- If the maximum number of concurrently existing child processes that will be generated by the monitoring target process is unclear, specify 65535 for the upper threshold of the number of monitoring target processes.

If the process operation status information could not be collected from the OS, the number of monitoring target processes might become 0 and an alarm might be reported. To prevent this alarm, from the Alarms window, open the New Alarm Table > Main Information window or the Edit > Main Information window. Then in **Advanced settings**, select **Report alarm when the following damping condition is reached** and specify **2 occurrence(s) during/Interval(s)**.

9.2.5 The message "KAVL17016-W Performance data was not saved to the Store database because it is the same as previous performance data." is output to the common message log

The KAVL17016-W message is output to the common message log and the collection of performance data can be skipped if: The amount of time it takes to complete the collection of performance data from all monitored hosts in the instance is more than the collection interval for the collection process (`Interval` setting value for the instance environment) and the collection interval for each performance data (`Collection Interval` setting value for each record).

Each collection interval should be set to a value with 15 or more seconds added to the time interval estimated based on the following estimation procedure:

How to estimate the value of the collection interval

Follow these steps to estimate the value of the collection interval:

1. Measure the collection periods for all monitored hosts.

Make measurements on the collection periods by performing the connection test steps, which are described in the notes about collecting records in the *Release Notes*. Determine the maximum value from the time periods required to collect the data for all the monitored hosts in these measurements.

#

As a guideline, the average time needed to collect performance data per monitored host is 5 seconds for a host running Windows and 20 seconds for one running UNIX. If your measurement results are much greater than these values, review your environment so that they can be closer to the average values above.

Note

How to check the collection period in the environment during operation

In the environment during operation, you can determine the collection period (the amount of time it takes to complete the collection of performance data from all monitored hosts in the instance) by calculating the difference between the start and end times of collection based on the log records in the PFM - RM for Platform log file as shown below:

Log file name

- In Windows
`installation-folder\agt7\agent\instance-name\log\timer_01`
- In UNIX
`installation-directory/agt7/agent/instance-name/log/timer_01`

Example records in the log file and how to calculate the collection period

Time when the collection started:

```
2016/03/16 11:20:10.135 TimerThread.cpp 141 I collecting start
```

Time when the collection ended:

```
2016/03/16 11:20:47.923 TimerThread.cpp 144 I collecting end
```

Collection period:

Time when the collection ended - Time when the collection started = 47.923 - 10.135 = Approximately 38 seconds

Also, you can determine the collection period for each monitored host by calculating the difference between the start and end times of collection, based on the log records in the PFM - RM for Platform log file as shown below.

Log file name

- In Windows
`installation-folder\agt7\agent\instance-name\log\target_monitored-host-name_01`
- In UNIX
`installation-directory/agt7/agent/instance-name/log/target_monitored-host-name_01`

Example records in the log file and how to calculate the collection period

- In Windows

Time when the collection started:

```
2016/03/16 11:20:19.575 WMI_Collector.cpp 58 I collect start
```

Time when the collection ended:

```
2016/03/16 11:20:26.024 WMI_Collector.cpp 261 I collect end
```

Collection period:

Time when the collection ended - Time when the collection started = 26.024 - 19.575 =

Approximately 6 seconds

- In UNIX

Time when the collection started:

```
2015/10/21 18:43:02.501 SSH_Collector.cpp 65 I collection start
```

Time when the collection ended:

```
2015/10/21 18:43:22.563 SSH_Collector.cpp 75 I collection end
```

Collection period:

Time when the collection ended - Time when the collection started = 22.563 - 2.501 = Approximately

20 seconds

2. Calculate the average number of hosts processed per thread for collecting performance data

PFM - RM for Platform uses 10 parallel threads to collect performance data. You can use the following formula to calculate the average number of hosts that are processed by a single thread which collects the data:

Average number of hosts per thread = Total number of monitored hosts / 10 (rounded up to the next whole number)

3. Determine the value set for the collection interval

Based on the values calculated in steps 1 and 2, use the following formula to calculate the value for the collection interval:

Collection interval value = (Maximum collection period determined in step 1 x Average number of hosts determined in step 2) + 15

9.2.6 Troubleshooting other problems

We recommend that you check the existing circumstances when other errors occur. If a message is output, check the details of the message. For details about the log information that is output by Performance Management, see [9.3 Log information to be collected for troubleshooting](#).

You might be unable to resolve an error by taking the steps described in this section or by referring to the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*. Also, an error other than those described in this section or chapter might not be resolvable. In such cases, collect the data needed to investigate the cause of the error and contact the system administrator.

For details about the data you need to collect and how to collect it, see [9.4 Data to be collected for troubleshooting](#) and [9.5 How to collect data for troubleshooting](#).

9.3 Log information to be collected for troubleshooting

When an error occurs in Performance Management, you need to check the log information and investigate the problem. The following five types of log information are output during operation of Performance Management:

- System log
- Common message log
- Operation status log
- Trace log
- Agent log

This section describes each type of log information.

9.3.1 Types of log information to be collected

(1) System log

The system log contains log information that reports the system status and errors that have occurred. This log information is output to the following file:

In Windows

Event log file

In UNIX

syslog file

For details about the output formats, see the chapter that describes log information in the manual *JP1/Performance Management Reference*.

Notes about logical host operation

In addition to the system log for Performance Management, you might need the log information for the cluster software in order to check such information as Performance Management control by the cluster software.

(2) Common message log

The common message log contains log information that reports the system status and errors that have occurred. The information output to this log is more detailed than the system log information. For details about the name and size of the file to which the common message log information is output, see [9.3.2 Log files and directories to check](#). For details about the output formats, see the chapter that describes log information in the manual *JP1/Performance Management Reference*.

Notes about logical host operation

When Performance Management is under logical host operation, the common message log is output to the shared disk. Because a log file on the shared disk is inherited together with the system during failover, messages are recorded in the same log file.

(3) Operation status log

The operation status log is the log information that is output by PFM - Web Console. For details about the name and size of the file to which the operation status log information is output, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*. For details about the output formats, see the chapter that describes log information in the manual *JPI/Performance Management Reference*.

(4) Trace log

The trace log is the log information that is collected in order to investigate the details of an error and determine the processing time required by each process when an error occurs. The trace log is output to a log file for each service of the Performance Management programs.

Notes about logical host operation

When Performance Management is under logical host operation, the common message log is output to the shared disk. Because a log file on the shared disk is inherited together with the system during failover, messages are recorded in the same log file.

(5) Agent log

The agent log is the log information for processing related to record collection. It is output by PFM - RM for Platform. In the event of an error, the agent log is collected in order to obtain detailed information about the processing. For details about the agent log, see [9.3.2\(3\) Agent log](#).

Format

The agent log is output in the following format:

```
yyyy/mm/dd hh:mm:ss.sss inf1 inf2 inf3 Message
```

The following table describes each item that is output.

Table 9–3: Items in the agent log

No.	Item	Description
1	yyyy/mm/dd	Date the log was output (year/month/day)
2	hh:mm:ss.sss	Local time the log was output (hour:minute:second.millisecond)
3	inf1 to inf3	Maintenance information
4	Message	Message

Note

Do not change the time at the PFM - RM host or the update date and time in the agent log file. If this information is changed, the agent log might not be output correctly because the output of the agent log uses information about the last update date and time of the log file.

9.3.2 Log files and directories to check

This subsection describes the log information that is output from Performance Management programs. For details about the name and size of the file to which the operation status log information is output, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

(1) Common message log

This subsection describes the common message log, which is one of the types of log information for Performance Management.

The following table lists the output sources, the log file names, and the amount of disk space used for Windows.

Table 9–4: File names of the common message log (for Windows)

No.	Type of log information	Output source	File name	Disk space used ^{#1} (kilobytes)
1	Common message log	Performance Management	<i>installation-folder</i> \log\jpclog{01 02} ^{#2}	2,048 (x 2)
2			<i>installation-folder</i> \log\jpclogw{01 02} ^{#2}	2,048 (x 2)
3	Common message log (for logical host operation)	Performance Management for logical host operation	<i>environment-folder</i> ^{#3} \jplpc\log\jpclog{01 02} ^{#2}	2,048 (x 2)
4			<i>environment-folder</i> ^{#3} \jplpc\log\jpclogw{01 02} ^{#2}	2,048 (x 2)

#1

The value in parentheses is the number of log files that can be created for a single service. For example, 2,048 (x 2) indicates that a maximum of two log files, each with a size of 2,048 kilobytes, can be created. In this case, the total available disk space must be 4,096 kilobytes.

#2

The value 01 or 02 is appended to the file name of the common message log.

Sequential file method (jpclog)

Log information is first output to the log file whose name ends with 01. When the maximum log file size is reached, the suffix at the end of the log file name is changed from 01 to 02, and a new log file with the suffix 01 is created. Log information is then output to the new 01 log file. If a log file with a name ending in 02 already exists, that log file will be overwritten when the 01 suffix is changed to 02. The most recent log information is always output to the log file with a 01 suffix.

Wrap-around file method (jpclogw)

Log information is first output to the log file whose name ends with 01. When the maximum log file size is reached, a new log file with the suffix 02 is created. Log information is then output to the new 02 log file. If a log file with a name ending in 02 already exists, all data is deleted from that log file, and then log information is output from the beginning of the file. Thereafter, the log files are used alternately.

For details about how to output log information to log files, see the chapter that describes detection of Performance Management failures in the *JP1/Performance Management User's Guide*.

#3

The environment folder is on the shared disk that was specified when the logical host was created.

The following table lists the output sources, the log file names, and the amount of disk space used for UNIX.

Table 9–5: File names of the common message log (for UNIX)

No.	Type of log information	Output source	File name	Disk space used ^{#1} (kilobytes)
1	Common message log	Performance Management	/opt/jp1pc/log/jpclog{01 02} ^{#2}	2,048 (x 2)
2			/opt/jp1pc/log/jpclogw{01 02} ^{#2}	2,048 (x 2)
3	Common message log (for logical host operation)	Performance Management for logical host operation	<i>environment-directory</i> ^{#3} /jp1pc/log/jpclog{01 02} ^{#2}	2,048 (x 2)
4			<i>environment-directory</i> ^{#3} /jp1pc/log/jpclogw{01 02} ^{#2}	2,048 (x 2)

#1

The value in parentheses is the number of log files that can be created for a single service. For example, 2,048 (x 2) indicates that a maximum of two log files, each with a size of 2,048 kilobytes, can be created. In this case, the total available disk space must be 4,096 kilobytes.

#2

The value 01 or 02 is appended to the file name of the common message log.

Sequential file method (jpclog)

Log information is first output to the log file whose name ends with 01. When the maximum log file size is reached, the suffix at the end of the log file name is changed from 01 to 02, and a new log file with the suffix 01 is created. Log information is then output to the new 01 log file. If a log file with a name ending in 02 already exists, that log file will be overwritten when the 01 suffix is changed to 02. The most recent log information is always output to the log file with a 01 suffix.

Wrap-around file method (jpclogw)

Log information is first output to the log file whose name ends with 01. When the maximum log file size is reached, a new log file with the suffix 02 is created. Log information is then output to the new 02 log file. If a log file with a name ending in 02 already exists, all data is deleted from that log file, and then log information is output from the beginning of the file. Thereafter, the log files are used alternately.

For details about how to output log information to the log files, see the chapter that describes detection of Performance Management failures in the *JP1/Performance Management User's Guide*.

#3

The environment directory is on the shared disk that was specified when the logical host was created.

(2) Trace log

This subsection describes the trace log, which is one of the types of log information for Performance Management.

The following table lists the output sources and the storage folder names for Windows.

Table 9–6: Names of trace log storage folders (for Windows)

No.	Type of log information	Output source	Folder name
1	Trace log	Action Handler service	<i>installation-folder</i> \bin\action\log\
2		Performance Management command	<i>installation-folder</i> \tools\log\

No.	Type of log information	Output source	Folder name
3	Trace log	Remote Monitor Collector service	<i>installation-folder</i> \agt7\agent\ <i>instance-name</i> \log\
4		Remote Monitor Store service	<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \log\
5		Status Server service	<i>installation-folder</i> \bin\statsvr\log\
6	Trace log (for logical host operation)	Action Handler service	<i>environment-folder</i> #\jplpc\bin\action\log\
7		Performance Management command	<i>environment-folder</i> #\jplpc\tools\log\
8		Remote Monitor Collector service	<i>environment-folder</i> #\jplpc\agt7\agent\ <i>instance-name</i> \log\
9		Remote Monitor Store service	<i>environment-folder</i> #\jplpc\agt7\store\ <i>instance-name</i> \log\

The environment folder is on the shared disk that was specified when the logical host was created.

The following table lists the output sources and the storage directory names for UNIX.

Table 9–7: Names of trace log storage directories (for UNIX)

No.	Type of log information	Output source	Directory name
1	Trace log	Action Handler service	/opt/bin/action/log/
2		Performance Management command	/opt/jplpc/tools/log/
3		Remote Monitor Collector service	/opt/jplpc/agt7/agent/ <i>instance-name</i> /log/
4		Remote Monitor Store service	/opt/jplpc/agt7/store/ <i>instance-name</i> /log/
5		Status Server service	/opt/jplpc/bin/statsvr/log/
6	Trace log (for logical host operation)	Action Handler service	<i>environment-directory</i> #/jplpc/bin/action/log/
7		Performance Management command	<i>environment-directory</i> #/jplpc/tools/log/
8		Remote Monitor Collector service	<i>environment-directory</i> #/jplpc/agt7/agent/ <i>instance-name</i> /log/
9		Remote Monitor Store service	<i>environment-directory</i> #/jplpc/agt7/store/ <i>instance-name</i> /log/

The environment directory is on the shared disk that was specified when the logical host was created.

(3) Agent log

This subsection describes the agent log of PFM - RM for Platform, which is one of the types of log information for Performance Management.

The following table lists the output sources, output targets, log file names, and disk space used for Windows.

Table 9–8: Agent log files (for Windows)

No.	Type of log information	Output source	Output target	File name	Default disk space used ^{#1} (megabytes)
1	Normal log	PFM - RM for Platform	<i>installation-folder</i> \\agt7\\agent \\instance-name \\log\\	collect_core_nn ^{#2}	3 (x 4) ^{#3}
2				collect_nn ^{#2}	
3				timer_core_nn ^{#2}	
4				timer_nn ^{#2}	
5				target_monitoring-target-name_nn ^{#2}	
6	Normal log (for logical host operation)	PFM - RM for Platform	<i>environment-folder</i> ^{#4} \\jplpc \\agt7\\agent \\instance-name \\log\\	collect_core_nn ^{#2}	3 (x 4) ^{#3}
7				collect_nn ^{#2}	
8				timer_core_nn ^{#2}	
9				timer_nn ^{#2}	
10				target_monitoring-target-name_nn ^{#2}	

#1

You can use the following methods to check and change the maximum file size for the agent log:

- `jpcconf inst` command
- Remote Monitor Configuration property in the PFM - Web Console window

For details about how to change the maximum file size with the `jpcconf inst` command, see [3.6.2 Updating an instance environment](#).

#2

The agent log uses the sequential method. First, log information is output to a log file with a file name ending with 01. When the size of the log file reaches the maximum limit, the end of the log file name changes from 01 to 02, and a new log file with a file name ending with 01 is created. After that, log information is output to the log file with the file name ending with 01. If a log file with a file name ending with 02 or higher already exists, that file is overwritten. The latest log data is always output to a log file with a file name ending with 01.

In the file name, *nn* indicate a number from 01 to 04.

#3

The value in parentheses is the number of log files. For example, 3 (x 4) indicates that a maximum of four log files, each with a size of 3 megabytes, can be created. In this case, the total available disk space must be 12 megabytes.

Use the following formula to estimate the amount of disk space used by agent logs per instance. The units are megabytes.

$(4 + \text{number-of-monitored-hosts}) \times 4 \times \text{Log_Size-value-specified-for-the-instance-environment}$

#4

The environment folder is on the shared disk that was specified when the logical host was created.

The following table lists the output sources, output targets, log file names, and disk space used for UNIX.

Table 9–9: Agent log files (for UNIX)

No.	Type of log information	Output source	Output target	File name	Default disk space used ^{#1} (megabytes)
1	Normal log	PFM - RM for Platform	/opt/jplpc/ agt7/agent/ <i>instance-name</i> /log/	collect_nn ^{#2}	3 (x 4) ^{#3}
2				timer_nn ^{#2}	
3				target_monitoring-target-name_nn ^{#2}	

No.	Type of log information	Output source	Output target	File name	Default disk space used ^{#1} (megabytes)
4	Normal log (for logical host operation)	PFM - RM for Platform	<i>environment-directory</i> ^{#4} /jplpc/agt7/agent/ <i>instance-name</i> /log/	collect_ <i>nn</i> ^{#2}	3 (x 4) ^{#3}
5				timer_ <i>nn</i> ^{#2}	
6				target_monitoring-target-name_ <i>nn</i> ^{#2}	

#1

You can use the following methods to check and change the maximum file size for the agent log:

- `jpcconf inst` command
- Remote Monitor Configuration property in the PFM - Web Console window

For details about how to change the maximum file size with the `jpcconf inst` command, see [3.6.2 Updating an instance environment](#).

#2

The agent log uses the sequential method. First, log information is output to a log file with a file name ending with 01. When the size of the log file reaches the maximum limit, the end of the log file name changes from 01 to 02, and a new log file with a file name ending with 01 is created. After that, log information is output to the log file with the file name ending with 01. If a log file with a file name ending with 02 or higher already exists, that file is overwritten. The latest log data is always output to a log file with a file name ending with 01.

In the file name, *nn* indicate a number from 01 to 04.

#3

The value in parentheses is the number of log files. For example, 3 (x 4) indicates that a maximum of four log files, each with a size of 3 megabytes, can be created. In this case, the total available disk space must be 12 megabytes.

Use the following formula to estimate the amount of disk space used by agent logs per instance. The units are megabytes.

$(2 + \text{number-of-monitored-hosts}) \times 4 \times \text{Log_Size-value-specified-for-the-instance-environment}$

#4

The environment directory is on the shared disk that was specified when the logical host was created.

9.4 Data to be collected for troubleshooting

This section describes the data that needs to be collected when an error has occurred.

Performance Management provides commands for collecting the needed data in the batch mode. Use the `jpcras` command to collect PFM - RM for Platform data. The tables in the following subsections indicate the data that can be collected by the `jpcras` command.

Note

The data collected by the `jpcras` command depends on options you specify when you execute the command. For details about the command's options and the data that is collected, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

Notes about logical host operation

The following notes apply to logical host operation:

- During logical host operation, Performance Management log information is stored on the shared disk. If the shared disk is online, you can use the `jpcras` command to also collect the log information on the shared disk in the batch mode.
- To investigate problems during failover, you need the information existing before and after the failover. This means that you need information from both the executing system and the standby system.
- When Performance Management runs on a logical host, its startup and termination are controlled by the cluster software. Therefore, you need information about the cluster software in order to investigate a Performance Management that is running on a logical host. Compare the cluster software operation and the Performance Management operation.

9.4.1 Data to be collected from a Windows environment

(1) Log information about the OS

The following table lists the log information about the OS that needs to be collected.

Table 9–10: Log information about the OS (for Windows)

No.	Type of information	Overview	Default file name	Collection by the <code>jpcras</code> command
1	System log	Windows event log	--	Y
2		WMI log	<i>system-folder</i> \system32\WBEM\Logs*#	Y
3	Process information	List of processes	--	Y
4	System file	hosts file	<i>system-folder</i> \system32\drivers\etc\hosts	Y
5		services file	<i>system-folder</i> \system32\drivers\etc\services	Y
6	OS information	System information	--	Y
7		Network status	--	Y
8		Host name	--	Y

No.	Type of information	Overview	Default file name	Collection by the jpcras command
9	OS information	Windows firewall information	--	Y
10	Dump information	Problem report and solution log file	<i>user-mode-process-dump-output-folder\program-name.process-ID.dmp</i> Example: jpcagt7.exe.2420.dmp	N

Legend:

Y: Can be collected

N: Cannot be collected

--: Not applicable

#

If you have set the log files to be output to a different folder, collect the data from the applicable folder.

(2) Information about Performance Management

The following table lists the Performance Management information that needs to be collected. In the case of a network connection error, you must also collect applicable files from the machine at the connection destination.

Table 9–11: Information about Performance Management (for Windows)

No.	Type of information	Overview	Default file name	Collection by the jpcras command
1	Common message log	Message log output from Performance Management (sequential file method)	<i>installation-folder\log\jpclog{01 02}#1</i>	Y
2		Message log output from Performance Management (wrap-around file method)	<i>installation-folder\log\jpclogw{01 02}#1</i>	Y
3	Configuration information	Each configuration information file	--	Y
4		Output results of the jpc tool service list command	--	Y
5	Version information	Product version	--	Y
6		Historical information	--	Y
7	Database information	Remote Monitor Store service	<ul style="list-style-type: none"> <i>installation-folder\agt7\store\instance-name\STPD</i> <i>installation-folder\agt7\store\instance-name\following-files-under-STPI-folder</i> <ul style="list-style-type: none"> *.DB *.IDX 	Y
8	Trace log	Trace information for each service of the Performance Management program	--#2	Y

No.	Type of information	Overview	Default file name	Collection by the jpcras command
9	Agent log	Normal log of the processing related to record collection by PFM - RM for Platform	<ul style="list-style-type: none"> <i>installation-folder\agt7\agent\instance-name\log\collect_{01 02 03 04}#3</i> <i>installation-folder\agt7\agent\instance-name\log\timer_{01 02 03 04}#3</i> <i>installation-folder\agt7\agent\instance-name\log\target_monitoring-target-name_{01 02 03 04}#3</i> 	Y
10	Work data	Work data during performance data collection	<ul style="list-style-type: none"> <i>installation-folder\agt7\agent\instance-name\targets*</i> <i>installation-folder\agt7\agent\instance-name\groups*</i> 	Y
11	Install log ^{#4}	Message log during installation	<i>system-folder\TEMP\HCDINST*.LOG</i>	N
12	Language environment information for system account	Language environment information for system account	<i>installation-folder\agt7\agent\instance-name\log\system_lang.log</i>	Y

Legend:

Y: Can be collected

N: Cannot be collected

--: Not applicable

#1

For details about how to output log information to the log files, see the chapter that describes detection of Performance Management failures in the *JPI/Performance Management User's Guide*.

#2

For details about the trace log storage folder, see [9.3.2\(2\) Trace log](#).

#3

For details about the agent log output method and the storage folder, see [9.3.2 Log files and directories to check](#).

#4

Collect this log information if installation fails. %TEMP% indicates the folder that is set in TEMP when the set command is executed at the command prompt.

(3) Software information

The following table lists the types of information that must be collected by the various software when you want to use PFM - RM for Platform to collect performance data.

Table 9–12: Software information

No.	Type of information	Overview	Acquiring command	Collection by the jpcras command
1	PuTTY	SSH client (plink) version information	<i>plink.exe -v#1</i>	Y
2	ActivePerl	Perl module (perl) version information	<i>perl.exe -v#2</i>	Y

Legend:

Y: Can be collected

#1

Specify the `-V` option for the absolute path name of the `plink.exe` command specified in `SSH_Client` when the instance environment was set up. Note that the command will not be executed in the following cases:

- `SSH_Client` is not specified.
- No file exists in the path specified in `SSH_Client`.
- The file name specified in `SSH_Client` is not `plink.exe`.

#2

Specify the `-V` option for the absolute path name of the `perl.exe` command specified in `Perl_Module` when the instance environment was set up. Note that the command will not be executed in the following cases:

- `Perl_Module` is not specified.
- No file exists in the path specified in `Perl_Module`.
- The file name specified in `Perl_Module` is not `perl.exe`.

(4) Operation information

You need the following information about the operation that was underway when an error occurred:

- Details of the operation
- Time the error occurred
- Machine configuration (such as the version of each OS, host name, and configuration of PFM - Manager and PFM - RM for Platform)
- Whether the problem is repeatable
- Performance Management user name used during login, if the user has logged on from PFM - Web Console
- Any arguments specified in a command, if the problem occurred during command execution

(5) Error information on screen displays

Obtain a hardcopy of the following information:

- The window operation when the application error occurred
- The error message dialog box (including the contents of detailed information if displayed)
- The Command Prompt window or the Administrator Console window, if the error occurred during command execution

(6) User-mode process dump

If a Performance Management process is stopped by an application error, collect a user-mode process dump.

(7) Collecting a problem report

If a Performance Management process is stopped by an application error, collect a problem report.

(8) Other information

You also need the following information:

- The contents of **System** and **Application** in the Event Viewer window of Windows
- The contents of **System Information**, which is displayed by choosing **Accessories**, and then **System Tools**

9.4.2 Data to be collected from a UNIX environment

(1) Log information about the OS

The following table lists the log information about the OS that needs to be collected.

Table 9–13: Log information about the OS (for UNIX)

No.	Type of information	Overview	Default file name	Collection by the jpcras command
1	System log	syslog	--	Y [#]
2	Process information	List of processes	--	Y
3	System file	hosts file	/etc/hosts	Y
4		services file	/etc/services	Y
5	OS information	Patch information	--	Y
6		Kernel information	--	Y
7		Version information	--	Y
8		Network status	--	Y
9		Environment variable	--	Y
10		Host name	--	Y
11	Dump information	core file	--	Y

Legend:

Y: Can be collected

--: Not applicable

#

If the system is set to output to a path and file name that are not the default, the information cannot be collected. Use an appropriate method to collect the data.

(2) Information about Performance Management

The following table lists the Performance Management information that needs to be collected. In the case of a network connection error, you must also collect applicable files from the machine at the connection destination.

Table 9–14: Information about Performance Management (for UNIX)

No.	Type of information	Overview	Default file name	Collection by the jpcras command
1	Common message log	Message log output from Performance Management (sequential file method)	/opt/jp1pc/log/jpclog{01 02} ^{#1}	Y
2		Message log output from Performance Management (wrap-around file method)	/opt/jp1pc/log/jpclogw{01 02} ^{#1}	Y

No.	Type of information	Overview	Default file name	Collection by the jpcras command
3	Configuration information	Each configuration information file	--	Y
4		Output results of the <code>jpctool service list</code> command	--	Y
5	Version information	Product version	--	Y
6		Historical information	--	Y
7	Database information	Remote Monitor Store service	<ul style="list-style-type: none"> <code>/opt/jplpc/agt7/store/instance-name/*.DB</code> <code>/opt/jplpc/agt7/store/instance-name/*.IDX</code> 	Y
8	Trace log	Trace information for each service of the Performance Management program	--#2	Y
9	Agent log	Normal log of the processing related to record collection by PFM - RM for Platform	<ul style="list-style-type: none"> <code>/opt/jplpc/agt7/agent/instance-name/log/collect_{01 02 03 04}#3</code> <code>/opt/jplpc/agt7/agent/instance-name/log/timer_{01 02 03 04}#3</code> <code>/opt/jplpc/agt7/agent/instance-name/log/target_monitoring-target-name_{01 02 03 04}#3</code> 	Y
10	Work data	Work data during performance data collection	<ul style="list-style-type: none"> <code>/opt/jplpc/agt7/agent/instance-name/targets/*</code> <code>/opt/jplpc/agt7/agent/instance-name/groups/*</code> 	Y
11	Install log#4	Standard log of Hitachi Program Product Installer	<ul style="list-style-type: none"> <code>/etc/.hitachi/.hitachi.log</code> <code>/etc/.hitachi/.hitachi.log{01 02 03 04 05}</code> <code>/etc/.hitachi/.install.log</code> <code>/etc/.hitachi/.install.log{01 02 03 04 05}</code> 	N

Legend:

Y: Can be collected

N: Cannot be collected

--: Not applicable

#1

For details about how to output log information to the log files, see the chapter that describes detection of Performance Management failures in the *JPI/Performance Management User's Guide*.

#2

For details about the trace log storage directory, see [9.3.2 Log files and directories to check](#).

#3

For details about the agent log output method and the storage directory, see [9.3.2 Log files and directories to check](#).

#4

Collect this log information if installation fails.

(3) Operation information

You need the following information about the operation that was underway when the error occurred:

- Details of the operation
- Time the error occurred
- Machine configuration (such as the version of each OS, host name, and configuration of PFM - Manager and PFM - RM for Platform)
- Whether the problem is repeatable
- Performance Management user name used during logon, if the user has logged on from PFM - Web Console
- Any arguments specified in a command, if the problem occurred during command execution

(4) Error information on screen displays

Obtain a hardcopy of the following information:

- The window operation when the application error occurred
- The messages output to the console, if the error occurred during command execution

9.5 How to collect data for troubleshooting

This section describes how to collect data in the event of an error.

9.5.1 How to collect data in a Windows environment

(1) Collecting dump information

To collect dump information:

1. Open Task Manager.
2. Select the **Processes** tab.
3. Right-click the name of the process for which a dump is to be collected and choose **Create Dump File**.

A dump file is stored in the following folder:

```
system-drive\Users\user-name\AppData\Local\Temp
```

4. Collect the dump files from the folder identified in step 3.

If you have changed the setting of the environment variable so that dump files are output to a different folder than the one described in step 3, collect the dump files from that alternate folder.

(2) Executing the data collection command

Use the `jpcras` command to collect data needed to determine the cause of an error. Note that an OS user with Administrator permissions must perform the procedure described below.

To execute the data collection command:

1. Log on to the host where the service subject to this data collection is installed.
2. At the command prompt, execute the following command to enable the command extensions of the command interpreter:

```
cmd /E:ON
```

3. Execute the `jpcras` command, with the data to be collected and the data storage folder to be used specified.

The following `jpcras` command stores all the available information in the `c:\tmp\jpc\agt` folder:

```
jpcras c:\tmp\jpc\agt all all
```

When you execute the `jpcras` command, the `jpctool service list -id * -host *` command is executed internally in order to obtain a list of PFM services and to check their activity status. If there is a firewall between the host where the command is executed and the host for the Performance Management system or if the system configuration is large, it might take a while for the `jpctool service list -id * -host *` command to execute. In such a case, you can suppress execution of the `jpctool service list -id * -host *` command, thus reducing the command execution time, by specifying 1 in the `JPC_COLCTRLNOHOST` environment variable.

For details about the `jpcras` command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

Important

If the user account control functionality (UAC) is enabled in the operating system, the user account control dialog box might appear during command execution. If this dialog box appears, click the **Continue** button to continue data collection. Clicking the **Cancel** button will cancel data collection.

(3) Executing a data collection command (operation on a logical host)

Performance Management information for logical host information is on the shared disk and must be collected in both the executing system and the standby system.

Use the `jpcras` command to collect data needed to determine the cause of an error. Note that an OS user with Administrator permissions must perform the procedure described below.

To execute the data collection command for logical host operation:

1. Place the shared disk online.

Information about the logical host is stored on the shared disk. At the executing node, make sure that the shared disk is online, and then collect the information.

2. Execute the `jpcras` command in both the executing system and the standby system, with the data to be collected and the data storage folder to be used specified.

The following `jpcras` command stores all the available information in the `c:\tmp\jpc\agt` folder:

```
jpcras c:\tmp\jpc\agt all all
```

Executing the `jpcras` command without the `lhost` argument specified collects all the Performance Management information on the physical and logical hosts at that node. If there is a Performance Management in the logical host environment, the log files on the shared disk are acquired.

If the `jpcras` command is executed at a node where the shared disk is offline, files will not be acquired from the shared disk, but the command will terminate normally without resulting in an error.

Note

Execute the data collection command at both the executing node and the standby node to collect information. To examine an event before and after failover, you need the information from both systems (executing and standby).

For details about the `jpcras` command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

3. Collect information about the cluster software.

This information is needed to determine whether the problem occurred in the cluster software or in Performance Management. Collect the information that provides control requests, such as startup and termination of Performance Management from the cluster software, and their results.

(4) Collecting the Windows event log

In the Windows Event Viewer window, collect the content of **System** and **Applications**.

(5) Checking information about the operation

Check and save information about the operation that was underway when the error occurred. The following lists the information that you need to check and save:

- Details of the operation
- Time the error occurred
- Machine configuration (such as the version of each OS, host name, and configuration of PFM - Manager and PFM - RM for Platform)
- Whether the problem is repeatable
- Performance Management user name used during logon, if the user has logged on from PFM - Web Console
- Any arguments specified in a command, if the problem occurred during command execution

(6) Collecting error information on screen displays

Obtain a hardcopy of the following information:

- The window operation when the application error occurred
- The error message dialog box
If there is detailed information, also make a hardcopy of that information.
- The Command Prompt window or the Administrator Console window, if the error occurred during command execution
To print the Command Prompt window or the Administrator Console window, specify the following settings for the Command Prompt Properties window:
 - **Edit options** on the **Options** page
Select **Quick Edit Mode**.
 - **Layout** page
For **Screen buffer size**, set **Height** to 500.

(7) Collecting other information

Collect other necessary information.

- Content of **Accessories > System Tools > System Information**

9.5.2 How to collect data in a UNIX environment

(1) Executing the data collection command

Use the `jpcras` command to collect data needed to determine the cause of an error. Note that an OS user with `root` user permissions must perform the procedure described below.

To execute the data collection command:

1. Log on to the host where the service subject to this data collection is installed.
2. Execute the `jpcras` command with the data to be collected and the data storage directory to be used specified.
The following `jpcras` command stores all the available information in the `/tmp/jpc/agt` directory:

```
jpcras /tmp/jpc/agt all all
```

The data collected by the data collection command is compressed and stored in the specified directory by the `tar` and `compress` commands. The file name is as follows:

```
jpcrasYYMMDD#.tar.Z
```

#: *YYMMDD* is replaced with the year, month, and day.

When you execute the `jpcras` command, the `jpctool service list -id * -host *` command is executed internally in order to obtain a list of PFM services and to check their activity status. If there is a firewall between the host where the command is executed and the host for the Performance Management system or if the system configuration is large, it might take a while for the `jpctool service list -id * -host *` command to execute. In such a case, you can suppress execution of the `jpctool service list -id * -host *` command, thus reducing the command execution time, by specifying `1` in the `JPC_COLCTRLNOHOST` environment variable.

For details about the `jpcras` command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

(2) Executing the data collection command (for logical host operation)

Performance Management information for logical host information is on the shared disk and must be collected in both the executing system and the standby system. Use the `jpcras` command to collect data needed to determine the cause of an error. Note that an OS user with the `root` user permissions must perform the procedure described below.

To execute the data collection command for logical host operation:

1. Mount the shared disk.

Information about the logical host is stored on the shared disk. At the executing node, make sure that the shared disk is mounted, and then collect the information.

2. Execute the `jpcras` command in both the executing system and the standby system, with the data to be collected and the data storage directory to be used specified.

The following `jpcras` command stores all the available information in the `/tmp/jpc/agt` directory:

```
jpcras /tmp/jpc/agt all all
```

The data collected by the data collection command is compressed and stored in the specified directory by the `tar` and `compress` commands. The file name is as follows:

```
jpcrasYYMMDD#.tar.Z
```

#: *YYMMDD* is replaced with the year, month, and day.

Executing the `jpcras` command without the `lhost` argument specified collects all the Performance Management information on the physical and logical hosts at that node. If there is a Performance Management in the logical host environment, the log files on the shared disk are acquired.

If the `jpcras` command is executed at a node where the shared disk is not mounted, files will not be acquired from the shared disk, but the command will terminate normally without resulting in an error.

Note

Execute the data collection command at both the executing node and the standby node to collect information. To examine an event before and after failover, you need the information from both systems (executing and standby).

For details about the `jpcras` command, see the chapter that describes commands in the manual *JPI/Performance Management Reference*.

3. Collect information about the cluster software.

This information is needed to determine whether the problem occurred in the cluster software or in Performance Management. Collect the information that provides control requests, such as startup and termination of Performance Management from the cluster software, and their results.

(3) Checking information about the operation

Check and save information about the operation that was underway when the error occurred. The following lists the information that you should check and save:

- Details of the operation
- Time the error occurred
- Machine configuration (such as the version of each OS, host name, and configuration of PFM - Manager and PFM - RM for Platform)
- Whether the problem is repeatable
- Performance Management user name used during logon, if the user has logged on from PFM - Web Console
- Any arguments specified in a command, if the problem occurred during command execution

(4) Collecting error information on screen displays

Collect the following error information:

- The messages that were output to the console, if the error occurred during command execution

9.6 Detecting problems within Performance Management

You can detect Performance Management errors by using JP1/Base, an integrated system monitoring product, to monitor the Performance Management log files. Performance Management also provides the status management function for checking the status of each service of PFM - Manager and PFM - RM for Platform in the event of an error. This function enables the system administrator to quickly detect an error, obtain the accurate status of the service that caused the error, and take appropriate action to recover the error.

Performance Management provides the health check function for detecting Performance Management errors. This function monitors the operating status of PFM - RM for Platform and PFM - RM host and displays the monitoring results on PFM - Web Console as changes in the operating status of PFM - RM for Platform. The automatic PFM service restart function enables the PFM service to be restarted automatically if the PFM service has stopped abnormally for some reason.

Use of the status management function that enables you to check the detailed status of Performance Management services is a prerequisite for using the health check function to monitor the operating status of PFM - RM for Platform and for using the automatic PFM service restart function to restart the PFM service automatically. Therefore, the target PFM - RM for Platform's version must support the status management function, and the status management function must be enabled. There are no prerequisite conditions for monitoring the operating status of the host. You can also use JP1/Base (integrated system monitoring product) to monitor the Performance Management log files in order to detect Performance Management errors. The system administrator can then detect a failure, identify the cause, and take appropriate action for recovery. For details about detection of Performance Management failures, see the chapter that describes detection of Performance Management failures in the *JP1/Performance Management User's Guide*.

9.7 Recovering from Performance Management system errors

If the Performance Management server fails, you must restore it from backup files to its normal status before the failure. For details about how to restore the status that existed before a failure, see the chapter that describes troubleshooting in the *JP1/Performance Management User's Guide*.

Appendixes

A. Estimating System Requirements

Before building a system, check whether the machine to be used is powerful enough to run PFM - RM for Platform.

A.1 Memory requirements

The memory requirements depend on the setup conditions and on the conditions under which PFM - RM for Platform will be used. The formula for estimating the memory requirements is available in the *Release Notes*.

A.2 Disk space requirements

The required disk space depends on the number of records to be used to store performance data.

To estimate the disk space required by PFM - RM for Platform, you must estimate the disk space required by the entire system and the disk space required by the Store database. The formulas for estimating these requirements are available in the *Release Notes*.

B. List of Identifiers

To operate PFM - RM for Platform or to extract performance data from the Store database of PFM - RM for Platform, identifiers might be required so that the system can identify PFM - RM for Platform. The following table shows the PFM - RM for Platform identifiers.

Table B–1: Identifiers of PFM - RM for Platform

Identifier	Name	Usage	Description
7	Product ID	Commands, etc.	The product ID is part of the service ID. The service ID is required when you use commands to check the configuration of the Performance Management system and when you back up performance data. For details about service IDs, see the naming rules provided in the appendix in the <i>JP1/Performance Management Planning and Configuration Guide</i> .
RMPlatform or agt7	Service key		This identifier is needed in order to use commands to start and stop PFM - RM for Platform. For details about service keys, see the naming rules provided in the appendix in the <i>JP1/Performance Management Planning and Configuration Guide</i> .
RM Platform	Product name	Display in GUI, etc.	The product name identifies the product and is used to display information in the PFM - Web Console windows.
pcm7	Help ID	Help	This is the identifier for the PFM - RM for Platform Help.

C. List of Processes

This appendix describes the functions of the PFM - RM for Platform processes.

Note

These processes and the number of processes also apply to a PFM - RM for Platform that runs on a logical host.

C.1 List of Processes (for Windows)

The following table lists and describes the processes of PFM - RM for Platform. The value in parentheses following each process name is the number of processes that can run concurrently.

Table C–1: Processes of PFM - RM for Platform (in Windows)

Process name (number of processes)	Function
jpcagt7.exe (<i>n</i>)	Process of the Remote Monitor Collector service. One process is started for each instance of PFM - RM for Platform.
jpcsto.exe (<i>n</i>)	Process of the Remote Monitor Store service. One process is started for each instance of PFM - RM for Platform.
jpc7collect.exe (<i>n</i>) ^{#1}	Collection process. One process is started for each instance of PFM - RM for Platform.
stpqlpr.exe (1) ^{#2}	Process for executing Store database backup and export.
jpc7corecollect64.exe (1) ^{#3}	Core collection process (64-bit edition)

#1

Child process of the jpcagt7.exe process

#2

Child process of the jpcsto.exe process

#3

Child process of the jpc7collect.exe process. The jpc7collect.exe process starts jpc7corecollect64.exe.

C.2 List of processes (for UNIX)

The following table lists and describes the processes of PFM - RM for Platform. The value in parentheses following each process name is the number of processes that can run concurrently.

Table C–2: Processes of PFM - RM for Platform (in UNIX)

Process name (number of processes)	Function
jpcagt7 (<i>n</i>)	Process of the Remote Monitor Collector service. One process is started for each instance of PFM - RM for Platform.
jpcsto (<i>n</i>)	Process of the Remote Monitor Store service. One process is started for each instance of PFM - RM for Platform.
jpc7collect (<i>n</i>) ^{#1}	Collection process. One process is started for each instance of PFM - RM for Platform.
stpqlpr (1) ^{#2}	Process for executing Store database backup and export.

- #1
Child process of the jpcagt7 process
- #2
Child process of the jpcsto process

D. List of Port Numbers

This appendix describes the port numbers used by PFM - RM for Platform.

For details about the port numbers for PFM - Manager and PFM - Base, and the firewall passage directions, see the appendix in the manual *JPI/Performance Management Reference*.

You can change port numbers as appropriate to your system environment. For details about how to change port numbers, see the chapter that describes installation and setup in the *JPI/Performance Management Planning and Configuration Guide*. The TCP/IP protocol is used.

Important

- Performance Management supports static NAT (Basic NAT), which performs one-to-one address conversion. Note, however, that PFM - RM for Platform does not support static NAT (Basic NAT) because WMI cannot resolve IP addresses based on NAT when the monitored host is running Windows.
- It does not support dynamic NAT or NAPT (IP Masquerade, NAT+), which include a port conversion function.

D.1 Port numbers for PFM - RM for Platform

The following table shows the port numbers used by PFM - RM for Platform.

Table D–1: Port numbers used by PFM - RM for Platform

Port number	Service name	Parameter	Usage
Automatic ^{#1}	Remote Monitor Collector service	jp1pcagt7[<i>nnn</i>] ^{#2}	Used to bind alarms and acquire real-time reports.
	Remote Monitor Store service	jp1pcsto7[<i>nnn</i>] ^{#2}	Used to record performance data and acquire historical reports.

^{#1}

If you execute the `jpccconf port define` command, a port number not being used at that time is automatically allocated and displayed. If you do not execute the `jpccconf port define` command, a port number not being used by the system is automatically allocated each time the service is restarted.

^{#2}

If multiple instances are created, a sequence number (*nnn*) is assigned to the second and subsequent instances that are created. No sequence number is assigned to the first instance that is created.

D.2 Firewall passage directions

This subsection describes the firewall passage directions for PFM - RM for Platform.

(1) Setting the firewall passage directions

If there is a firewall between PFM - Manager and PFM - RM for Platform, you must set fixed port numbers for all services of PFM - Manager and PFM - RM for Platform. For details, see the section that describes firewall passage directions in the manual *JPI/Performance Management Reference*.

(a) When the monitored host is running Windows

The port numbers used for WMI is 135/tcp and the port number# assigned by the OS.

#

WMI uses DCOM. Because DCOM uses dynamic port allocation, the port used for DCOM must pass through the firewall.

The following are the standard ranges of ports assigned by the OS:

- For Windows Server 2003: 1025 to 5000
- For Windows Server 2008 or later: 49152 to 65535

For details about the setup method, see the firewall product documentation or contact the firewall product developer. Usage with a firewall is not suitable because one WMI and DCOM request cannot be separated from another WMI and DCOM request. The following figure shows the recommended configuration.

Figure D–1: Example of an acceptable configuration for passing through a firewall with the port used in DCOM

(b) When the monitored host is running UNIX

Specify the settings so that the port number specified in the settings for the monitoring target of PFM - RM for Platform is used to pass through the firewall.

The table below shows the values that can be specified for the port number, which is a monitoring target setting. For details about the monitoring target settings, see [3.2.4 Setup procedure for the UNIX edition](#).

Table D–2: Port numbers permitted for the monitoring target setting

Setting item	Description	Permitted value	Default value
Port	Port number of the SSH server on the monitored host	From 1 to 65,535	22

(2) Setting the firewall passage directions (when the health check function is used)

If PFM - RM for Platform is to monitor the operating status of a monitored host using the health check function, you must specify the settings so that ICMP communication passes through the firewall.

The following table shows the firewall passage directions.

Table D–3: Firewall passage directions (between PFM - RM for Platform and a monitored host)

Service name	Communication protocol	Passage direction
Remote Monitor Collector service	ICMP echo request/ICMP echo response	PFM - RM host ← → monitored host

Legend:

← →: Direction in which communication (connection) begins, from the left-hand item to the right-hand item or from the right-hand item to the left-hand item.

E. Properties of PFM - RM for Platform

This appendix describes the properties of the following services and agents of PFM - RM for Platform that are displayed in PFM - Web Console:

- Remote Monitor Store service
- Remote Monitor Collector service
- Remote agents and group agents

E.1 List of properties of the Remote Monitor Store service

The following table lists and describes the properties of the Remote Monitor Store service of PFM - RM for Platform.

Table E–1: List of properties of the Remote Monitor Store service of PFM - RM for Platform

Directory name	Property name	Description
--	First Registration Date	Displays the first date and time the service was recognized by PFM - Manager.
	Last Registration Date	Displays the most recent date and time the service was recognized by PFM - Manager.
General	--	Stores information such as host names and directories. You cannot change properties stored in this directory.
	Directory	Displays the name of the current directory where the service is running.
	Host Name	Displays the name of the physical host where the service is running.
	Process ID	Displays the service's process ID.
	Physical Address	Displays the IP address and port number of the host where the service is running when the IPv6 communication facility is disabled.
	Physical Address (IPv4)	Displays the IP address (IPv4) of the host where the service is running when the IPv6 communication facility is enabled.
	Physical Address (IPv6)	Displays the IP address (IPv6) of the host where the service is running when the IPv6 communication facility is enabled.

Directory name		Property name	Description
General		Port Number	Displays the port number being used by the service that is running when the IPv6 communication facility is enabled.
		User Name	Displays the name of the user that executed the service process.
		Time Zone	Displays the time zone in which the service is used.
System		--	Stores information about the OS where the service is running. You cannot change properties stored in this directory.
		CPU Type	Displays the CPU type.
		Hardware ID	Displays the hardware ID.
		OS Type	Displays the OS type.
		OS Name	Displays the OS name.
		OS Version	Displays the OS version.
Network Services		--	Stores information about the Performance Management communication common library. You cannot change properties stored in this folder.
		Build Date	Displays the creation date of the Remote Monitor Store service.
		INI File	Displays the name of the directory containing the <code>jpcns.ini</code> file.
Network Services	Service	--	Stores information about the service. You cannot change properties stored in this folder.
		Description	Displays the host name in the following format: <i>instance-name_host-name</i>
		Local Service Name	Displays the service ID.
		Remote Service Name	Displays the service ID of the Master Manager service at the connection-target PFM - Manager host.
		EP Service Name	Displays the service ID of the Correlator service at the connection-target PFM - Manager host.
Retention		--	Specifies the data retention period when using Store version 1.0. Because the Remote Monitor Store service is not

Directory name		Property name	Description
Retention		--	support by Store version 1.0, you cannot change the properties stored in this directory.
		Product Interval - Minute Drawer	Displays the retention period for records of the PI record type that are collected every minute. The permitted value is fixed at Day.
		Product Interval - Hour Drawer	Displays the retention period for records of the PI record type that are collected hourly. The permitted value is fixed at Day.
		Product Interval - Day Drawer	Displays the retention period for records of the PI record type that are collected daily. The permitted value is fixed at 2Days.
		Product Interval - Week Drawer	Displays the retention period for records of the PI record type that are collected weekly. The specifiable value is fixed at Week.
		Product Interval - Month Drawer	Displays the retention period for records of the PI record type that are collected monthly. The permitted value is fixed at Month.
		Product Interval - Year Drawer	Displays the retention period for records of the PI record type that are collected yearly. The permitted value is fixed at Year.
Retention Ex		--	Sets the data retention period for Store version 2.0. For details, see the chapter that describes management of operation monitoring data in the <i>JP1/Performance Management User's Guide</i> .
Retention Ex	Product Interval - <i>record-ID-of-PI-record-type</i>	--	Sets the retention period for records of the PI record type.
		Period - Minute Drawer (Day)	Specifies the retention period for records of the PI record type that are collected every minute. You can specify from 0 to 366 days in 1-day increments.
		Period - Hour Drawer (Day)	Sets the retention period for records of the PI record type that are collected hourly. The permitted value is an integer in the range from 0 to 366 (days).
		Period - Day Drawer (Week)	Sets the retention period for records of the PI record type that

Directory name		Property name	Description
Retention Ex	Product Interval - <i>record-ID-of-PI-record-type</i>	Period - Day Drawer (Week)	are collected daily. The permitted value is an integer in the range from 0 to 522 (weeks).
		Period - Week Drawer (Week)	Sets the retention period for records of the PI record type that are collected weekly. The permitted value is an integer in the range from 0 to 522 (weeks).
		Period - Month Drawer (Month)	Sets the retention period for records of the PI record type that are collected monthly. The permitted value is an integer in the range from 0 to 120 (months).
		Period - Year Drawer (Year)	Sets the retention period for records of the PI record type that are collected yearly. The permitted value is from 10 (fixed).
	Product Detail - <i>record-ID-of-PD-record-type</i>	Period (Day)	Sets the retention period for records of the PD record type for each record ID. The permitted value is an integer in the range from 0 to 366 (days).
Disk Usage		--	Stores the amount of disk space being used by each database. The property stored in this directory displays the disk usage in effect when the property is displayed. You cannot change properties stored in this directory.
		Product Interval	Displays the amount of disk space used by records of the PI record type.
		Product Detail	Displays the amount of disk space used by records of the PD record type.
		Product Alarm	Displays the amount of disk space used by records of the PA record type. PFM - RM for Platform does not use this property.
		Product Log	Displays the amount of disk space used by records of the PL record type. PFM - RM for Platform does not use this property.
		Total Disk Usage	Displays the amount of disk space used by the entire database.
Configuration		--	Displays the properties of the Remote Monitor Store service.

Directory name	Property name	Description
Configuration	Store Version	Displays the version of the Store database.
Multiple Manager Configuration	Primary Manager	Displays the host name of the monitoring manager specified as the primary manager for multiple monitoring. You cannot change this property.
	Secondary Manager	Displays the host name of the monitoring manager specified as the secondary manager for multiple monitoring. You cannot change this property.

Legend:

--: Not applicable

E.2 List of properties of the Remote Monitor Collector service

The following table lists and describes the properties of the Remote Monitor Collector service of PFM - RM for Platform.

Table E–2: List of properties of the Remote Monitor Collector service of PFM - RM for Platform

Directory name	Property name	Description
--	First Registration Date	Displays the first date and time the service was recognized by PFM - Manager.
	Last Registration Date	Displays the most recent date and time the service was recognized by PFM - Manager.
	Data Model Version	Displays the version of the data model.
General	--	Stores information such as host names and directories. You cannot change properties stored in this directory.
	Directory	Displays the name of the current directory where the service is running.
	Host Name	Displays the name of the physical host on which the service runs.
	Process ID	Displays the process ID of the service.
	Physical Address	Displays the IP address and port number of the host where the service is running when the IPv6 communication facility is disabled.
	Physical Address (IPv4)	Displays the IP address (IPv4) of the host where the service is running when the IPv6

Directory name		Property name	Description
General		Physical Address (IPv4)	communication facility is enabled.
		Physical Address (IPv6)	Displays the IP address (IPv6) of the host where the service is running when the IPv6 communication facility is enabled.
		Port Number	Displays the port number being used by the service that is running when the IPv6 communication facility is enabled.
		User Name	Displays the name of the user that executed the service process.
		Time Zone	Displays the time zone in which the service is being used.
System		--	Stores information about the OS where the service is running. You cannot change properties stored in this directory.
		CPU Type	Displays the CPU type.
		Hardware ID	Displays the hardware ID.
		OS Type	Displays the OS type.
		OS Name	Displays the OS name.
		OS Version	Displays the OS version.
Network Services		--	Stores information about the Stores information Performance Management communication common library. You cannot change properties stored in this directory.
		Build Date	Displays the creation date of the Remote Monitor Collector service.
		INI File	Displays the name of the directory containing the <code>jpcns.ini</code> file.
Network Services	Service	--	Stores information about the service. You cannot change properties stored in this directory.
		Description	Displays the host name in the following format: <i>instance-name_host-name</i>
		Local Service Name	Displays the service ID.

Directory name		Property name	Description
Network Services	Service	Remote Service Name	Displays the service ID of the Remote Monitor Store service to which the Remote Monitor Collector service is connected.
		EP Service Name	Displays the service ID of the Correlator service on the connection-target PFM - Manager host.
		AH Service Name	Displays the service ID of the Action Handler service on the connection-target PFM - Manager host.
JP1 Event Configurations		--	Specifies the condition for issuing JP1 events.
		Services	Specifies whether Yes or No was selected for the list items in the Remote Monitor Collector service, Remote Monitor Store service, Action Handler service, and Status Server service to issue a JP1 system event for each service.
		JP1 Event Send Host	Specifies the connection-target event server name of JP1/Base. You can only specify an event server that is running on the logical host or physical host of the same machine as that on which the Action Handler service is running. You can specify from 0 to 255 bytes of single-byte alphanumeric characters, including periods (.) or hyphens (–). If you specify a value that is outside the permitted range, it is treated as if the specification was omitted. If the value is omitted, the host where the Action Handler service is running is used as the event-issuing host. If localhost is specified, it is assumed that you mean the physical host.
		Monitoring Console Host	This property specifies the PFM - Web Console host to be started when the service that browses it is automatically executed by the startup of the JP1/IM - Manager monitor. You can specify from 0 to 255 bytes of single-byte alphanumeric characters, including periods (.) or hyphens (–). If you specify a value that is outside the permitted range, it is treated as if the specification was omitted.

Directory name		Property name	Description
JP1 Event Configurations		Monitoring Console Host	If the value is omitted, the connection-target PFM - Manager host is assumed.
		Monitoring Console Port	Specifies the port number (http request port number) on which the PFM - Web Console is to be started. You can specify from 1 to 65535. If you specify a value that is outside the permitted range, it is treated as if the specification was omitted. If the value is omitted, 20358 is set.
		Monitoring Console Https	Specifies whether to connect to the PFM - Web Console via https-based encrypted communications when the PFM - Web Console is started by the startup of the JP1/IM - Manager monitor. The default is No. <ul style="list-style-type: none"> • Yes: Uses encrypted communications. • No: Does not use encrypted communications.
JP1 Event Configurations	Alarm	JP1 Event Mode	Specifies whether to issue a JP1 system event or a JP1 user event when the alarm status changes. <ul style="list-style-type: none"> • JP1 User Event: Issues a JP1 user event. • JP1 System Event: Issue a JP1 system event.
Detail Records		--	Stores the properties of records of the PD record type. The record IDs of the collected records are displayed in boldface type.
Detail Records	<i>record-ID</i> ^{#1}	--	Stores the properties of a record.
		Description	Displays a description of the record. You cannot change this property.
		Log	Displays Yes or No, indicating whether records are to be recorded in the Store database of PFM - RM for Platform. No is always displayed here.
		Log (ITSMLM)	Displays Yes or No, indicating whether records are to be recorded in the Store database of PFM - RM for Platform from JP1/SLM - Manager when JP1/SLM - Manager is linked. If JP1/SLM - Manager is not linked, this property is fixed at No. You cannot change this property.

Directory name		Property name	Description
Detail Records	<i>record-ID</i> ^{#1}	Monitoring (ITSML)	Displays Yes or No, based on the setting in JP1/SLM - Manager, indicating whether records are to be sent to JP1/SLM - Manager when JP1/SLM - Manager is linked. If JP1/SLM - Manager is not linked, this property is fixed at No. You cannot change this property.
		Collection Interval ^{#2}	Specifies the data collection interval. The permitted value is from 0 to 2,147,483,647 seconds in increments of 1. If you specify 0 for the property, 0 seconds is assumed, in which case no data is collected.
		Collection Offset ^{#2}	Specifies the offset value (in seconds) for starting data collection. This value must be in the range from 0 to 32,767 seconds but cannot exceed the value specified for Collection Interval. The data collection logging time does not depend on the Collection Offset value and is the same as the Collection Interval.
		Sync Collection With ^{#2}	Displays the records whose collection is to be synchronized, in <i>record-type</i> , <i>record-ID</i> format.
		Over 10 Sec Collection Time	Displays record collection time only when historical data collection takes priority over real-time report display processing ^{#3} . Whether the collection of records takes 10 seconds or longer is displayed as Yes or No. <ul style="list-style-type: none"> • Yes: Sometimes takes 10 seconds or longer. • No: Takes less than 10 seconds. You cannot change this property.
		LOGIF	Specifies the conditions for storing records in the database. Only records that satisfy the conditions are stored in the database. The system displays the conditional expression (character string) that was created in the LOGIF Expression Editor window, which is displayed by clicking LOGIF in the lower frame of

Directory name		Property name	Description
Detail Records	<i>record-ID</i> ^{#1}	LOGIF	the properties window for the service that is displayed on PFM - Web Console's Services page.
Interval Records		--	Stores the properties of records of the PI record type. The record IDs of the collected records are displayed in boldface type.
Interval Records	<i>record-ID</i> ^{#1}	--	Stores the properties of a record.
		Description	Displays a description of the record. You cannot change this property.
		Log	Displays Yes or No indicating whether records are to be recorded in the Store database of PFM - RM for Platform. No is always displayed here.
		Log (ITSML)	Displays Yes or No , indicating whether records are to be recorded in the Store database of PFM - RM for Platform from JP1/SLM - Manager when JP1/SLM - Manager is linked. If JP1/SLM - Manager is not linked, this property is fixed at No . You cannot change this property.
		Monitoring (ITSML)	Displays Yes or No , based on the setting in JP1/SLM - Manager, indicating whether records are to be sent to JP1/SLM - Manager when JP1/SLM - Manager is linked. If JP1/SLM - Manager is not linked, this property is fixed at No . You cannot change this property.
		Collection Interval	Specifies the data collection interval. The permitted value is from 0 to 2,147,483,647 seconds in increments of 1. If you specify 0 for the property, 0 seconds is assumed, in which case no data is collected.
		Collection Offset	Specifies the offset value (in seconds) for starting data collection. This value must be in the range from 0 to 32,767 seconds but cannot exceed the value specified for Collection Interval. The data collection logging time does not depend on the Collection Offset value and is the same as the Collection Interval.

Directory name		Property name	Description
Interval Records	<i>record-ID</i> ^{#1}	Over 10 Sec Collection Time	Displays record collection time only when historical data collection takes priority over real-time report display processing ^{#3} . Whether the collection of records takes 10 seconds or longer is displayed as Yes or No. <ul style="list-style-type: none">• Yes: Sometimes takes 10 seconds or longer.• No: Takes less than 10 seconds. You cannot change this property.
		LOGIF	Specifies the conditions for storing records in the database. Only records that satisfy the conditions are stored in the database. The system displays the conditional expression (character string) that was created in the LOGIF Expression Editor window, which is displayed by clicking LOGIF in the lower frame of the properties window for the service that is displayed on PFM - Web Console's Services page.
Log Records		--	Stores the properties of records of the PL type. PFM - RM for Platform does not use this property.
Monitoring Targets		--	Stores the properties of the monitored host that is monitored by PFM - RM for Platform.
Monitoring Targets	<i>monitoring-target-name</i>	--	Displays a description of the monitoring target. As many descriptions are displayed as there are monitoring targets.
		Target Name	Displays the name of the monitoring target. You cannot change this property.
		Target Host	Displays the name of the monitored host. You cannot change this property.
Health Check Configurations		Health Check for Target Hosts	Specifies whether to poll monitored hosts. This property applies to all monitored hosts in an instance.
Restart Configurations		--	Specifies the conditions for automatically restarting the PFM service.

Directory name		Property name	Description
Restart Configurations		Restart when Abnormal Status	Specifies whether to automatically restart a service when the Status Server service cannot normally acquire the status of the Action Handler service, Remote Monitor Collector service, and Remote Monitor Store service.
		Restart when Single Service Running	Specifies whether to automatically restart a service when only the Remote Monitor Store service or Remote Monitor Collector service has started.
Restart Configurations	Remote Monitor Collector	Auto Restart	Specifies whether to use the auto restart function on the Remote Monitor Collector service.
		Auto Restart - Interval (Minute)	Specifies the interval at which to check the operation status of a service when the auto restart function is used. You can specify from 1 to 1,440 minutes in 1-minute increments.
		Auto Restart - Repeat Limit	Specifies the number of continuous retries, as an integer from 1 to 10, when the auto restart function is used.
		Scheduled Restart	Select Yes or No from the list items to indicate whether the scheduled restart function will be used on the Remote Monitor Collector service.
		Scheduled Restart - Interval	Specifies the restart interval, as an integer from 1 to 1000, when the scheduled restart function is used.
		Scheduled Restart - Interval Unit	Select Day, Week, or Month from the item list to indicate the unit for the restart interval when the scheduled restart function is used.
		Scheduled Restart - Origin - Year	Specifies the year when a restart will be executed, as an integer from 1971 to 2035.
		Scheduled Restart - Origin - Month	Specifies the month when a restart will be executed, as an integer from 1 to 12.
		Scheduled Restart - Origin - Day	Specifies the day when a restart will be executed, as an integer from 1 to 31.

Directory name		Property name	Description
Restart Configurations	Remote Monitor Collector	Scheduled Restart - Origin - Hour	Specifies the time (hour) when a restart will be executed, as an integer from 0 to 23.
		Scheduled Restart - Origin - Minute	Specifies the time (minutes) when a restart will be executed, as an integer from 0 to 59.
	Remote Monitor Store	Auto Restart	Specifies whether to use the auto restart function on the Remote Monitor Store service.
		Auto Restart - Interval (Minute)	Specifies the interval at which to check the operation status of a service when the auto restart function is used. You can specify from 1 to 1,440 minutes in 1-minute increments.
		Auto Restart - Repeat Limit	Specifies the number of continuous retries, as an integer from 1 to 10, when the auto restart function is used.
		Scheduled Restart	Select Yes or No from the item list to indicate whether the scheduled restart function will be used on the Remote Monitor Store service.
		Scheduled Restart - Interval	Specifies the restart interval, as an integer from 1 to 1000, when the scheduled restart function is used.
		Scheduled Restart - Interval Unit	Select Day, Week, or Month from the item list to indicate the unit for the restart interval when the scheduled restart function is used.
		Scheduled Restart - Origin - Year	Specifies the year when a restart will be executed, as an integer from 1971 to 2035.
		Scheduled Restart - Origin - Month	Specifies the month when a restart will be executed, as an integer from 1 to 12.
		Scheduled Restart - Origin - Day	Specifies the day when a restart will be executed, as an integer from 1 to 31.
		Scheduled Restart - Origin - Hour	Specifies the time (hour) when a restart will be executed, as an integer from 0 to 23.
		Scheduled Restart - Origin - Minute	Specifies the time (minutes) when a restart will be executed, as an integer from 0 to 59.
	Action Handler	Auto Restart	Specifies whether to use the auto restart function on the Action Handler service.

Directory name		Property name	Description
Restart Configurations	Action Handler	Auto Restart - Interval (Minute)	Specifies the interval at which to check the operation status of a service when the auto restart function is used. You can specify from 1 to 1,440 minutes in 1-minute increments.
		Auto Restart - Repeat Limit	Specifies the number of continuous retries, as an integer from 1 to 10, when the auto restart function is used.
		Scheduled Restart	Select Yes or No from the item list to indicate whether the scheduled restart function will be used on the Action Handler service.
		Scheduled Restart - Interval	Specifies the restart interval, as an integer from 1 to 1000, when the scheduled restart function is used.
		Scheduled Restart - Interval Unit	Select Day, Week, or Month from the item list to indicate the unit for the restart interval when the scheduled restart function is used.
		Scheduled Restart - Origin - Year	Specifies the year when a restart will be executed, as an integer from 1971 to 2035.
		Scheduled Restart - Origin - Month	Specifies the month when a restart will be executed, as an integer from 1 to 12.
		Scheduled Restart - Origin - Day	Specifies the day when a restart will be executed, as an integer from 1 to 31.
		Scheduled Restart - Origin - Hour	Specifies the time (hour) when a restart will be executed, as an integer from 0 to 23.
		Scheduled Restart - Origin - Minute	Specifies the time (minutes) when a restart will be executed, as an integer from 0 to 59.
ITSLM Connection Configuration		--	Displays information about the JP1/SLM - Manager that is linked.
ITSLM Connection Configuration	ITSLM Connection	--	Displays information about the connection-target JP1/SLM - Manager.
		ITSLM Host	Displays the host name of the connected JP1/SLM - Manager. This property is not displayed when JP1/SLM - Manager is not connected.
		ITSLM Port	Displays the port number of the connected JP1/SLM - Manager.

Directory name		Property name	Description
ITSLM Connection Configuration	ITSLM Connection	ITSLM Port	This property is not displayed when JP1/SLM - Manager is not connected.
	MANAGE ITSLM CONNECTION	--	Specifies whether to terminate the connection to JP1/SLM - Manager.
		DISCONNECT ITSLM CONNECTION	Specifies from the item list the host name of the JP1/SLM - Manager whose connection is to be terminated. If a blank character is specified from the item list, no action is taken. Only a blank character is displayed in the item list if JP1/SLM - Manager is not connected.
Multiple Manager Configuration		Primary Manager	Displays the host name of the manager specified as the primary manager for multiple monitoring. You cannot change this property.
		Secondary Manager	Displays the host name of the manager specified as the secondary manager for multiple monitoring. You cannot change this property.
Remote Monitor Configuration		--	Stores the setting properties specific to PFM - RM for Platform.
Remote Monitor Configuration	Remote Monitor	--	Displays an overview of the Remote Monitor Collector service.
		Product	Displays 7 as the product ID.
		Instance	Displays the instance name specified in the jpccconf inst setup command.
		UseCommonAccount	Displays the value of UseCommonAccount, which was specified when the instance environment was set up. You cannot change this property. This property is supported only when the PFM - RM host is running Windows.
		Interval	Displays the value of Interval, which was specified when the instance environment was set up. You can change this property.
		Std_Category	Displays the value of StdCategory, which was specified when the instance

Directory name		Property name	Description
Remote Monitor Configuration	Remote Monitor	Std_Category	environment was set up. You can change this property.
		Disk_Category	Displays the value of DiskCategory, which was specified when the instance environment was set up. You can change this property.
		Network_Category	Displays the value of NetworkCategory, which was specified when the instance environment was set up. You can change this property.
		Ps_Category	Displays the value of PsCategory specified when the instance environment was set up. You can change this property.
		RMHost_User	<ul style="list-style-type: none"> Displays the value of RMHost_User, which was specified when the instance environment was set up. You can change this property.^{#4} Displays the value of User in common account information (pfmhost) when Y is specified for UseCommonAccount. <p>This property is supported only when the PFM - RM host is running Windows.</p>
		RMHost_Password	<p>**** (fixed) is displayed. You cannot change this property.</p> <p>This property is supported only when the PFM - RM host is running Windows.</p>
		RMHost_Domain	<ul style="list-style-type: none"> Displays the value of RMHost_Domain, which was specified when the instance environment was set up. You can change this property.^{#4} Displays the value of Domain in common account information (pfmhost) when Y is specified for UseCommonAccount. You cannot change this property. <p>This property is supported only when the PFM - RM host is running Windows.</p>

Directory name		Property name	Description
Remote Monitor Configuration	Remote Monitor	SSH_Client	Displays the value specified in SSH_Client when the instance environment was set up. You can change this property. This property is supported only when the PFM - RM host is running Windows. You must specify this property when the monitored host is running UNIX.
		Perl_Module	Displays the value specified in Perl_Module when the instance environment was set up. You can change this property. This property is supported only when the PFM - RM host is running Windows. You must specify this property when the monitored host is running UNIX.
		Log_Size	Displays the value of Log_Size, which was specified when the instance environment was set up. You can change this property.
		Use_Processor_Information_Object	Displays Yes or No indicating whether the Win32_PerfRawData_Counters_ProcessorInformation class is used to collect processor information. <ul style="list-style-type: none"> • Yes: The Win32_PerfRawData_Counters_ProcessorInformation class is used to collect CPU information. • No: The Win32_PerfRawData_PerfOS_Processor class is used to collect CPU information. You can change this property.

Legend:

--: Not applicable

#1

The directory name shows the record ID without the database ID. For details about the record ID of each record, see [7. Records](#).

#2

If Sync Collection With is displayed, Collection Interval and Collection Offset are not displayed.

#3

For details, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

#4

To apply the new values, restart the Remote Monitor Collector service.

E.3 List of properties of remote agents and group agents

The following table lists and describes the properties of remote agents and group agents of PFM - RM for Platform.

Table E–3: List of properties of remote agents and group agents of PFM - RM for Platform

Directory name		Property name	Description	Remote agent	Group agent
--		First Registration Date	Displays the first date and time the service was recognized by PFM - Manager.	D	D
		Last Registration Date	Displays the most recent date and time the service was recognized by PFM - Manager.	D	D
		Data Model Version	Displays the version of the data model.	D	D
Remote Monitoring		--	Stores the properties of the remote agent or group agent.	D	D
		Agent Type	Displays the type of Agent: <ul style="list-style-type: none"> Remote Agent: For remote agent Group Agent: For group agent 	D	D
		Remote Monitor Name	Displays the service ID of PFM - RM for Platform.	D	D
		Target Name	Displays the name of the monitoring target.	D	N
		Target Host	Displays the name of the monitored host.	D	N
		Group Name	Displays the group name.	N	D
		Primary Host	Displays the primary host name.	N	D
		Grouping Targets	Displays a list of target names that are to be summarized.	N	D
Detail Records		--	Stores the properties of records of the PD record type. The record IDs of the collected records are displayed in boldface type.	D	D
Detail Records	<i>record-ID</i> ^{#1}	--	Stores the properties of a record.	D	D
		Description	Displays a description of the record.	D	D
		Log ^{#2, #3}	Displays Yes or No indicating whether records are to be recorded in the Store database of PFM - RM for Platform. If this value is	U	U

Directory name		Property name	Description	Remote agent	Group agent
Detail Records	<i>record-ID</i> ^{#1}	Log ^{#2, #3}	set to Yes and Collection Interval is set to a value greater than 0, records are recorded into the database.	U	U
		Log (ITSML) ^{#2, #3}	Displays Yes or No indicating whether records are to be recorded in the Store database of PFM - RM for Platform from JP1/SLM - Manager. If this value is set to Yes and Collection Interval is set to a value greater than 0, the record is recorded into the database. You cannot change this property.	D	D
		Monitoring (ITSML)	Displays Yes or No, based on the setting in JP1/SLM - Manager, indicating whether records are to be sent to JP1/SLM - Manager. You cannot change this property.	D	D
		Collection Interval ^{#4}	Specifies the data collection interval. The permitted value is from 0 to 2,147,483,647 seconds in increments of 1. If you specify 0 for the property, 0 seconds is assumed, in which case no data is collected.	D ^{#5}	D ^{#5}
		Collection Offset ^{#4}	Specifies the offset value (in seconds) for starting data collection. This value must be in the range from 0 to 32,767 seconds but cannot exceed the value specified for Collection Interval. The data collection logging time does not depend on the Collection Offset value and is the same as the Collection Interval.	D ^{#5}	D ^{#5}
		Sync Collection With ^{#4}	Displays the records whose collection is to be synchronized, in <i>record-type</i> , <i>record-ID</i> format.	D	D
		Over 10 Sec Collection Time	Displays record collection time only when historical data collection takes priority over real-time report display processing ^{#6} . Whether the collection of records takes 10 seconds or	D	D

Directory name		Property name	Description	Remote agent	Group agent
Detail Records	record-ID ^{#1}	Over 10 Sec Collection Time	longer is displayed as Yes or No. <ul style="list-style-type: none">Yes: Sometimes takes 10 seconds or longer.No: Takes less than 10 seconds. You cannot change this property.	D	D
		Realtime Report Data Collection Mode	Displays report data collection mode only when historical data collection takes priority over real-time report display processing ^{#6} . Specify either of the following real-time report display modes: <ul style="list-style-type: none">Reschedule: Reschedule modeTemporary Log: Temporary log mode If you specify Yes for Over 10 Sec Collection Time, you must specify Temporary Log (temporary log mode) for this property.	U	U
		LOGIF	Specifies the conditions for storing records in the database. Only records that satisfy the conditions are stored in the database. The system displays the conditional expression (character string) that was created in the LOGIF Expression Editor window, which is displayed by clicking LOGIF in the lower frame of the properties window for the service that is displayed on PFM - Web Console's Services page.	D ^{#5}	D ^{#5}
Interval Records		--	Stores the properties of records of the PI record type. The record IDs of the collected records are displayed in boldface type.	D	D
Interval Records	record-ID ^{#1}	--	Stores the properties of a record.	D	D
		Description	Displays a description of the record. You cannot change this property.	D	D

Directory name		Property name	Description	Remote agent	Group agent
Interval Records	<i>record-ID</i> ^{#1}	Log ^{#3}	Displays Yes or No indicating whether records are to be recorded in the Store database of PFM - RM for Platform. If this value is set to Yes and Collection Interval is set to a value greater than 0, records are recorded in the database.	U	U
		Log (ITSML) ^{#3}	Displays Yes or No indicating whether records are to be recorded in the Store database of PFM - RM for Platform from JP1/SLM - Manager. If this value is set to Yes and Collection Interval is set to a value greater than 0, the record is recorded into the database. You cannot change this property.	D	D
		Monitoring (ITSML)	Displays Yes or No, based on the setting in JP1/SLM - Manager, indicating whether records are to be sent to JP1/SLM - Manager. You cannot change this property.	D	D
		Collection Interval	Specifies the data collection interval. The permitted value is from 0 to 2,147,483,647 seconds in increments of 1. If you specify 0 for the property, 0 seconds is assumed, in which case no data is collected.	D ^{#5}	D ^{#5}
		Collection Offset	Specifies the offset value (in seconds) for starting data collection. This value must be in the range from 0 to 32,767 seconds but cannot exceed the value specified for Collection Interval. The data collection logging time does not depend on the Collection Offset value and is the same as the Collection Interval.	D ^{#5}	D ^{#5}
		Over 10 Sec Collection Time	Displays record collection time only when historical data collection takes priority over real-time report display processing ^{#6} . Whether the collection of records takes 10 seconds or	D	D

Directory name		Property name	Description	Remote agent	Group agent
Interval Records	record-ID ^{#1}	Over 10 Sec Collection Time	longer is displayed as Yes or No. <ul style="list-style-type: none">• Yes: Sometimes takes 10 seconds or longer.• No: Takes less than 10 seconds. You cannot change this property.	D	D
		Realtime Report Data Collection Mode	Displays report data collection mode only when historical data collection takes priority over real-time report display processing ^{#6} . Specify either of the following real-time report display modes: <ul style="list-style-type: none">• Reschedule: Reschedule mode• Temporary Log: Temporary log mode If you specify Yes for Over 10 Sec Collection Time, you must specify Temporary Log (temporary log mode) for this property.	U	U
		LOGIF	Specifies the conditions for storing records in the database. Only records that satisfy the conditions are stored in the database. The system displays the conditional expression (character string) that was created in the LOGIF Expression Editor window, which is displayed by clicking LOGIF in the lower frame of the properties window for the service that is displayed on PFM - Web Console's Services page.	D ^{#5}	D ^{#5}
Log Records		--	Stores the properties of records of the PL type. PFM - RM for Platform does not use this property.	D	D
Remote Monitor Configuration		--	Stores the setting properties specific to the monitoring target.	D	N
Remote Monitor Configuration	Target	--	Displays an overview of the service of the remote agent.	D	N

Directory name		Property name	Description	Remote agent	Group agent
Remote Monitor Configuration	Target	UseCommonAccount	Displays Y or N to indicate whether to use common account information. <ul style="list-style-type: none"> Y: Use N: Do not use You cannot change this property.	D	D
		TargetType	Displays the method to be used for connecting to the monitored host. You cannot change this property. <ul style="list-style-type: none"> wmi: WMI (when the monitored host is also running Windows) ssh: SSH (when the monitored host is also running UNIX) icmp: Health check monitoring 	D	N
		User	<ul style="list-style-type: none"> Specifies the user ID to be used for connecting to the monitored host. Displays the value^{#7} specified in common account information when Y is specified for UseCommonAccount. You cannot change this property. This property is supported only when the monitored host is running Windows or UNIX.	U	N
		Password	**** (fixed) is displayed. You cannot change this property. This property is supported only when the monitored host is running Windows.	D	N
		Domain	<ul style="list-style-type: none"> Specifies the domain name to which the monitored host belongs. Displays the value of Domain in common account information (wmi) when Y is specified for UseCommonAccount. You cannot change this property. This property is supported only when the monitored host is running Windows.	U	N

Directory name		Property name	Description	Remote agent	Group agent
Remote Monitor Configuration	Target	Private_Key_File	<ul style="list-style-type: none"> Specifies the name of the private key file that is to be used with the SSH public key method. Displays the value of Private_Key_File in common account information (ssh) when Y is specified for UseCommonAccount. You cannot change this property. <p>This property is supported only when the monitored host is running UNIX.</p>	U	N
		Port	<p>This is the port number of the SSH server on the monitored host.</p> <p>This property is supported only when the monitored host is running UNIX.</p>	U	N
	Application monitoring setting		<p>Case Sensitive</p> <p>Specifies whether comparisons when evaluating monitoring condition will be case-sensitive.</p> <ul style="list-style-type: none"> Yes: Case-sensitive No: Not case-sensitive 	U	N
	Application monitoring setting	<i>application-name</i> ^{#8}	--	D	N
		Virtual Environment ID	<p>Specifies a maximum of 63 bytes as a virtual environment identifier for specifying the range of data to be collected from the processes for PD_APP2, PD_APPC, and PD_APPD records.</p> <p>If this property is not specified, data is collected from all processes.</p>	U	N
		Monitoring[01-15] Label ^{#9}	<p>Specifies a maximum of 31 bytes as the name for identifying the monitoring condition.</p> <p>By default, Monitoring [01-15] is set. If this property is not specified, Monitoring [01-15] is set.</p> <p>You must specify a unique value for this property.</p>	U	N

Directory name			Property name	Description	Remote agent	Group agent
Remote Monitor Configuration	Application monitoring setting	<i>application-name</i> ^{#8}	Monitoring[01-15] Field ^{#9}	Displays the fields to be monitored. <ul style="list-style-type: none">None: Not specifiedProgram Name: Refers to the value in the Program Name field of the PD_APS record.Command Line: Refers to the value in the Command Line field of the PD_APS record.Service Name: Refers to the value in the Service Name field of the PD_ASVC record.	U	N
			Monitoring[01-15] Condition ^{#9}	Specifies a maximum of 127 bytes for the monitoring condition when using a version of PFM - RM for Platform that is earlier than 10-00. Specifies a maximum of 4,096 bytes for the monitoring condition when using version 10-00 (or later) of PFM - RM for Platform.	U	N
			Monitoring[01-15] Range ^{#9}	Specifies the lower and upper threshold values for the number of monitoring targets, connecting the two values with a hyphen (–), such as 1–2. You can specify from 0 to 65535.	U	N
	ADDITION OR DELETION A SETTING		ADD AN APPLICATION MONITORING SETTING	Specifies a maximum of 63 bytes for the name of the application to be added. You must specify a unique value for this property.	U	N
			DELETE AN APPLICATION MONITORING SETTING	Specifies the name of the application to be deleted. By default, no application name is displayed.	U	N

Legend:

- : Not applicable
- U: Displayed and updatable
- D: Displayed but not updatable
- N: Not displayed

#1

The directory name shows the record ID without the database ID. For details about the record ID of each record, see [7. Records](#).

#2

For PD_APPD, PD_APS, and PD_ASVC records, the value of this property is fixed at No. (You cannot change it to Yes.)

#3

If either of these property values are `Yes`, records are recorded in the Store database.

#4

If `Sync Collection With` is `displayed`, `Collection Interval` and `Collection Offset` are not displayed.

#5

The value set by PFM - RM for Platform is displayed.

#6

For details, see the chapter that describes troubleshooting in the *JPI/Performance Management User's Guide*.

#7

If the PFM - RM host is running Windows:

If the value of `TargetType` indicates that the monitored host is running Windows, the value of `User` in common account information (`wmi`) is displayed.

If the value of `TargetType` indicates that the monitored host is running UNIX, the value of `User` in common account information (`ssh`) is displayed.

If the PFM - RM host is running UNIX:

The value of `User` in common account information (`ssh`) is displayed.

#8

For the directory name, the application specified in the `ADD AN APPLICATION MONITORING SETTING` property is displayed.

#9

In the specification of `Monitoring[01-15] Label`, `Monitoring[01-15] Field`, `Monitoring[01-15] Condition`, and `Monitoring[01-15] Range`, `[01-15]` means that a number from 01 to 15 is entered there. For example, when actual property items are displayed, they would appear as `Monitoring01 Label`, `Monitoring06 Field`, `Monitoring10 Condition`, or `Monitoring15 Range`.

F. List of Directories and Files

This appendix lists the directories and files of PFM - RM for Platform.

F.1 List of folders and files (for Windows)

The following table lists the folders and files for the Windows edition of PFM - RM for Platform.

Table F–1: List of folders and files for PFM - RM for Platform (for Windows)

Folder name	File name	Description
<i>installation-folder\</i>	--	Installation folder or environment folder
	<i>instagt7.ini</i>	Intermediate file for internal processing
<i>installation-folder\agt7\</i>	--	Base folder of PFM - RM for Platform
	<i>insrules.dat</i>	Intermediate file for internal processing
	<i>jpcagtras.bat</i>	Maintenance data collection program
	<i>PATCHLOG.TXT</i>	Intermediate file for internal processing
	<i>readme_language code.txt</i>	Readme text
	<i>version.txt</i>	Version information
<i>installation-folder\agt7\agent\</i>	--	Base folder of the Remote Monitor Collector service
	<i>agtlist.ini</i>	Intermediate file for internal processing
	<i>GARULES.DAT</i>	Grouping rule description file (master)
	<i>jpcagt.ini.instmpl</i>	Intermediate file for internal processing
	<i>jpcagt7.exe</i>	Executable program of the Remote Monitor Collector service
	<i>target.ini.tmpl</i>	Template file for setting the monitoring target
	<i>group.ini.tmpl</i>	Template file for setting the group agent
	<i>targetrules.dat</i>	Monitoring target creation rule file
<i>installation-folder\agt7\agent\instance-name\</i>	--	Base folder of the Remote Monitor Collector service. Files under this folder are created for each instance.

Folder name	File name	Description
<i>installation-folder</i> \agt7\agent\ <i>instance-name</i> \	GARULES.DAT	Grouping rule description file
	grouplist.ini	List of groups
	jpcagt.ini	Service startup initialization file of Remote Monitor Collector
	jpcagt.ini.model	Sample of a service startup initialization file of Remote Monitor Collector
	status.dat	Intermediate file for internal processing
	suspended.dat	Monitoring suspension information file
	targetlist.ini	List of monitoring targets
	tstatuses.dat	Virtual Agent status information ^{#1}
<i>installation-folder</i> \agt7\agent\ <i>instance-name</i> \groups\	--	Folder for the group agent
	<i>group-name</i> .ini	Group agent settings file
<i>installation-folder</i> \agt7\agent\ <i>instance-name</i> \log\	--	Storage folder for the internal log file of the Remote Monitor Collector service (for each instance)
	collect_core_ <i>nn</i> ^{#2}	Internal log file
	collect_ <i>nn</i> ^{#2}	
	timer_core_ <i>nn</i> ^{#2}	
	timer_ <i>nn</i> ^{#2}	
	target_monitoring-target-name_ <i>nn</i> ^{#2}	
	<ul style="list-style-type: none"> • msglog01 • msglog02 	
	<ul style="list-style-type: none"> • nslog01 • nslog02 	
<i>installation-folder</i> \agt7\agent\ <i>instance-name</i> \targets\	--	Folder for the remote agent
	<i>monitoring-target-name</i> .ini	Monitoring target settings file
	<i>monitoring-target-name</i> .ini.model	Sample of a monitoring target settings file
	<i>monitoring-target-name</i> _jpcapp	Application definition file
	<i>monitoring-target-name</i> _suspended.dat	Monitoring suspension information file

Folder name	File name	Description
<i>installation-folder</i> \agt7\agent\ <i>instance-name</i> \targets\	corecollect.stderr	Result of collection process (stderr)
	corecollect.stdout	Result of collection process (stdout)
<i>installation-folder</i> \agt7\agent\ <i>instance-name</i> \targets\ <i>monitoring-target-name</i> \	--	Work folder
	records.dat	Performance information file
	records.stdout	Performance information file ^{#3}
	records.stderr_NNN ^{#4}	Error information collection file
	common.stdout_NNN ^{#4}	Result of a common command (stdout)
	common.stderr_NNN ^{#4}	Result of a common command (stderr)
	os.stdout_NNN ^{#4}	Result of an OS-specific command (stdout)
	os.stderr_NNN ^{#4}	Result of an OS-specific command (stderr)
	wmi.out_NNN ^{#4}	wmi performance information file
<i>installation-folder</i> \agt7\bin\	--	Command storage folder
	jpc7collect.exe	Collection process
	jpc7corecollect64.exe	Collection child process (64-bit edition)
	jpcagt7hcc64.dll	HCCLib common library (64-bit edition)
<i>installation-folder</i> \agt7\dat\	--	Data storage directory for collection processes
	common.dat	Storage file for common execution commands
	cmd2rec	File creation script for record information
	cmd2rec_common	File creation script for record information (common to all OSs)
	cmd2rec_OS	File creation script for record information (for each OS)
	OS.dat	Execution command storage file for each category (for each OS)
<i>installation-folder</i> \agt7\lib\	--	Storage folder for libraries
	jpcagt7msg.dll	Message catalog file

Folder name	File name	Description
<i>installation-folder</i> \agt7\store\	--	Base folder of the Remote Monitor Store service
	STDICT.DAT	Data model definition file
	STRULES.DAT	
	stolist.ini	Intermediate file for internal processing
	jpcsto.ini.instmpl	
<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \	--	Base folder of the Remote Monitor Store service. Files under this folder are created for each instance.
	*.DB	Performance data files
	*.IDX	Index files for performance data files
	*.LCK	Lock files for performance data files
	jpcsto.ini	Service startup initialization file of Remote Monitor Store
	jpcsto.ini.model	Sample of a service startup initialization file of Remote Monitor Store
	status.dat	Intermediate file for internal processing
	STDICT.DAT	Data model definition file
	STRULES.DAT	
<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \backup\	--	Default database backup folder
<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \dump\	--	Default database export folder
<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \import\	--	Default database import folder
<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \log\	--	Internal log file storage folder for the Remote Monitor Collector service
	<ul style="list-style-type: none"> msglog01 msglog02 	Internal log file
	<ul style="list-style-type: none"> nslog01 nslog02 	
<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \partial\	--	Default database partial backup folder
<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \STPD\	--	PD record storage folder
<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \STPI\	--	
<i>installation-folder</i> \agt7\store\ <i>instance-name</i> \STPL\	--	

Folder name	File name	Description
<i>installation-folder</i> \log\	--	Common log folder
	jpclog*	Common logs
<i>installation-folder</i> \setup\	--	Setup file storage folder
	extract	Extraction folder for setup information
	jpcagt7u.Z	Archive file for PFM - RM for Platform setup (UNIX)
	jpcagt7w.EXE	Archive file for PFM - RM for Platform setup (Windows)
<i>installation-folder</i> \patch_files\agt7\	--	Storage folder for patch files (for agent)

Legend:

--: Not applicable

#1

Created if the health check function is enabled.

#2

nn is from 01 to 04.

#3

This folder is created temporarily.

#4

NNNN can be any value from 0002 to 0012.

The re-distribution files for Visual Studio are also installed. The following table lists and describes the re-distribution files for Visual Studio 2010 that are installed.

Table F–2: List of re-distribution files for Visual Studio 2010 that are installed in a Windows environment

Folder name	File name	Description
%Systemroot%\system32	msvcp100.dll	Microsoft Visual C++ 2010 SP1 CRT redistributable file (x64)

F.2 List of directories and files (for UNIX)

The following table lists the directories and files for the UNIX edition of PFM - RM for Platform.

Table F–3: List of directories and files for PFM - RM for Platform (for UNIX)

Directory name	File name	Permission	Description
<i>installation-directory</i> /	--	755	Installation folder or environment directory
	instagt7.ini	644	Intermediate file for internal processing
<i>installation-directory</i> /agt7/	--	755	Base directory of PFM - RM for Platform

Directory name	File name	Permission	Description
<i>installation-directory/agt7/</i>	<i>insrules.dat</i>	444	Intermediate file for internal processing
	<i>jpcagtras</i>	555	Maintenance data collection program
	<i>patch_history</i>	644	Intermediate file for internal processing
	<i>PATCHLOG.TXT</i>		
<i>installation-directory/agt7/.ssh/</i>	--	700	Directory for storing private and public key files
	<i>agt7</i>	600	Private key file
	<i>agt7.pub</i>	644	Public key file
<i>installation-directory/agt7/agent/</i>	--	755	Base directory of the Remote Monitor Collector service
	<i>agtlst.ini</i>	644	Intermediate file for internal processing
	<i>GARULES.DAT</i>	444	Grouping rule description file (master)
	<i>jpcagt.ini.instmpl</i>		Intermediate file for internal processing
	<i>jpcagt7</i>	555	Executable program of the Remote Monitor Collector service
	<i>target.ini.tmpl</i>	444	Template file for setting the monitoring target
	<i>group.ini.tmpl</i>		Template file for setting the group agent
	<i>targetrules.dat</i>		Monitoring target creation rule file
<i>installation-directory/agt7/agent/ instance-name/</i>	--	755	Base directory of the Remote Monitor Collector service. Files under this directory are created for each instance.
	<i>GARULES.DAT</i>	444	Grouping rule description file
	<i>grouplist.ini</i>	644	List of groups
	<i>jpcagt.ini</i>	600	Service startup initialization file of Remote Monitor Collector
	<i>jpcagt.ini.lck</i>	777	Lock file for the service startup initialization file of Remote Monitor Collector (for each instance)
	<i>jpcagt.ini.model</i>	444	Sample of a service startup initialization file of Remote Monitor Collector
	<i>status.dat</i>	600	Intermediate file for internal processing
	<i>suspended.dat</i>	644	Monitoring suspension information file
	<i>targetlist.ini</i>	644	List of monitoring targets

Directory name	File name	Permission	Description
<i>installation-directory/agt7/agent/ instance-name/</i>	tstatus.dat	600	Virtual Agent status information ^{#1}
<i>installation-directory/agt7/agent/ instance-name/groups/</i>	--	755	Directory for the group agent
	group-name.ini	644	Group agent settings file
<i>installation-directory/agt7/agent/ instance-name/log/</i>	--	777	Storage directory for the internal log file of the Remote Monitor Collector service (for each instance)
	collect_nn ^{#2}	666	Internal log file
	timer_nn ^{#2}		
	target_monitoring-target-name_nn ^{#2}		
	<ul style="list-style-type: none"> msglog01 msglog02 		
	<ul style="list-style-type: none"> nslog01 nslog02 		
<i>installation-directory/agt7/agent/ instance-name/targets/</i>	--	755	Directory for the remote agent
	monitoring-target-name.ini	600	Monitoring target settings file

#1

Created if the health check function is enabled.

#2

nn is from 01 to 04.

#3

NNNN is from 0002 to 0012.

The following table lists the LANG directories for the UNIX edition of PFM - RM for Platform.

Table F–4: List of LANG directories

Value of LANG	Description
C	English catalog
ja_JP.SJIS	Catalog for SJIS
ja_JP.UTF-8	Catalog for UTF-8
ja_JP.eucJP	Catalog for EUC
ja_JP.ujis	Symbolic link to ja_JP.eucJP
ja_JP.utf8	Symbolic link to ja_JP.UTF-8

G. Migration Procedure and Notes on Migration

To upgrade PFM - RM for Platform, perform an overwrite installation of PFM - RM for Platform.

In Windows

See *3.1 Installation and setup of the Windows edition*.

In UNIX

See *3.2 Installation and setup of the UNIX edition*.

For notes about upgrading the Performance Management programs, see the section that presents the notes on upgrading in the chapter and appendix describing installation and setup in the *JP1/Performance Management Planning and Configuration Guide*.

The following are notes about upgrading PFM - RM for Platform:

- When you upgrade PFM - RM for Platform, do not uninstall the earlier version of PFM - RM for Platform. If you uninstall it, all the data created by the earlier version (such as performance data) will also be deleted and will no longer be available under the later version.
- When you perform an overwrite installation of the PFM - RM for Platform program, the following items are updated automatically:
 - Store database files for the Remote Monitor Store service
 - INI file
 - Instance environments for PFM - RM for Platform

H. Version Compatibility

There are different versions of the PFM - RM for Platform product as well as different versions of the data model.

Because the data model has upward compatibility, you can use report and alarm definitions created under an earlier version of the data model with a later version.

The following table shows the correspondence between versions for PFM - RM for Platform.

Table H–1: Correspondence between versions for PFM - RM for Platform

PFM - RM for Platform version	Data model version	Alarm table version for monitoring template
09-00	4.0	09.00
09-10	5.0	09.10
09-50	5.0	09.10
10-00	5.0	09.10
10-50	5.0	09.10
11-00	5.0	09.10
11-10	5.0	09.10

For details about version compatibility, see the description of version compatibility in the appendix in the *JPI/Performance Management Planning and Configuration Guide*.

I. Outputting Action Log Data

Performance Management action logs consist of historical information whose output is linked with the alarm function for exceeded threshold values, such as system overloads.

For example, action logs are output when the PFM services start and stop, and when the status of the connection with PFM - Manager changes.

You can output action logs if the version of PFM - Manager or PFM - Base is 08-11 or later.

Action logs constitute a text file in CSV format. You can use them as analysis data by saving them periodically and processing them with a spreadsheet software program.

Output of action logs is set by `jpccomm.ini`. This appendix describes the information that is output as action logs by PFM - RM for Platform and PFM - Base and how to set output of action logs.

I.1 Types of events that are output to action logs

The table below lists and describes the types of events that are output to action logs and when the action logs are output by PFM - RM for Platform and PFM - Base. The entries in the *Type of event* column are identifiers that are used to classify the events that are output to action logs.

Table I-1: Types of events that are output to action logs

Type of event	Description	When output by PFM - RM for Platform or PFM - Base
StartStop	Event indicating startup or termination of software	<ul style="list-style-type: none">At startup and termination of PFM servicesAt startup and termination of the stand-alone mode
ExternalService	<ul style="list-style-type: none">Event indicating the result of communication between JP1 products and external servicesEvent indicating the occurrence of an abnormal communication	At a change in the status of the connection with PFM - Manager
ManagementAction	<ul style="list-style-type: none">Event indicating execution of an important program actionEvent indicating execution of an action based on another audit category	At execution of an automatic action

I.2 Storage format of action logs

This subsection describes the storage format of the action log file.

Action log information is output to the default file (current output file). When that file becomes full, new action log information is saved in a different file (shift file).

To swap action log files:

1. Action logs are output sequentially to the current output file `jpcaudit.log`.
2. When the current output file becomes full, new operation logs are output to a shift file.

The shift file name is the current output file name to which a number is appended. Each time the current output file becomes full, the shift file is renamed to *file-name-number+1*. Therefore, an older file has a larger number at the end of the file name.

Example:

When the current output file `jpcaudit.log` becomes full, its contents are saved to the shift file `jpcaudit1.log`.

When the current output file becomes full again, the existing shift file `jpcaudit1.log` is renamed to `jpcaudit2.log` and the contents of the current output file are moved to `jpcaudit1.log`.

When the number of log files reaches its maximum value (specified in the `jpccomm.ini` file), the oldest log file is deleted.

3. The current output file is initialized and new action logs are written.

The `jpccomm.ini` file is used to specify information about whether action logs are to be output, the output destination, and the maximum number of storage files. For details about how to set the `jpccomm.ini` file, see [I.4 Action log output settings](#).

I.3 Output format of action logs

Information about audit events is output to the Performance Management action logs. A separate action log file is output for each host. An action log's output destination host is as follows:

- When a service is executed
Action logs are output to the host where the service is running.
- When a command is executed
Action logs are output to the host that executed the command.

The following describes the output format, output destination, and output items for action logs.

(1) Output format

`CALFHM x.x, output-item-1=value-1, output-item-2=value-2, . . . , output-item-n=value-n`

(2) Output destination

`installation-folder\auditlog\`

You can use the `jpccomm.ini` file to change the output destination of action logs. For details about how to set the `jpccomm.ini` file, see [I.4 Action log output settings](#).

(3) Output items

There are two types of output items:

Common output items

Output items common to all JP1 products that output action logs

Fixed output items

Optional items that are output by JP1 products that output action logs

(a) Common output items

The table below lists and describes the common output items and their values, including the items that are output by PFM - Manager.

Table I–2: Common output items for action logs

Output item		Value	Description
Item name	Output attribute		
Common specification identifier	--	CALFHM	Identifier indicating that this is the action log format
Common specification revision number	--	<i>x.x</i>	Revision number used for managing action logs
Sequence number	seqnum	<i>sequence-number</i>	Sequence number of action log records
Message ID	msgid	KAVExxxx-x	Message ID
Date and time	date	YYYY-MM-DDThh:mm:ss.sssTZD [#]	Output date, time, and time zone of an action log
Generated program name	progid	JP1PFM	Name of the program where the event occurred
Generated component name	compid	<i>service-ID</i>	Name of the component where the event occurred
Generated process ID	pid	<i>process-ID</i>	Process ID of the process where the event occurred
Generated location	ocp:host	<ul style="list-style-type: none"> <i>host-name</i> <i>IP-address</i> 	Location where the event occurred
Event type	ctgry	<ul style="list-style-type: none"> StartStop Authentication ConfigurationAccess ExternalService AnomalyEvent ManagementAction 	Category names used to classify the events that are output to action logs
Event result	result	<ul style="list-style-type: none"> Success Failure Occurrence 	Result of the event
Subject identification information	subj:pid	<i>process-ID</i>	One of the following: <ul style="list-style-type: none"> Process ID that is run by the user operation Process ID that caused the event User name that caused the event Identification information assigned to users on a 1:1 basis
	subj:uid	<i>account-identifier</i> (PFM user/JP1 user)	
	subj:euid	<i>effective-user-ID</i> (OS user)	

Legend:

--: None

#

T indicates a separator between date and time.

TZD is the time zone specifier. One of the following is output:

+*hh:mm*: Advanced from UTC by *hh:mm*

-*hh:mm*: Delayed from UTC by *hh:mm*

Z: Same as UTC.

(b) Fixed output items

The table below lists and describes the fixed output items and their values, including the items that are output by PFM - Manager.

Table I–3: Fixed output items for action logs

Output item		Value	Description
Item name	Output attribute		
Object information	obj	<ul style="list-style-type: none">• <i>service-ID-of-PFM-RM</i>• <i>added-deleted-or-updated-user-name</i> (PFM user)	Operation target
	obj:table	<i>alarm-table-name</i>	
	obj:table	<i>alarm-name</i>	
Action information	op	<ul style="list-style-type: none">• Start• Stop• Add• Update• Delete• Change Password• Activate (enable)• Inactivate (disable)• Bind• Unbind	Action that caused the event
Permissions information	auth	<ul style="list-style-type: none">• Administrator user Management• General user Ordinary• Windows Administrator• UNIX SuperUser	Permissions of the user who performed the operation
	auth:mode	<ul style="list-style-type: none">• PFM authentication mode pfm• JP1 authentication mode jp1• OS user os	Authentication mode of the user who performed the operation
Output source	outp:host	<i>name-of-PFM-Manager-host</i>	Host that output the action log
Instruction source	subjp:host	<ul style="list-style-type: none">• <i>name-of-logon-host</i>• <i>name-of-executing-host</i> (only during execution of the <code>jpccalarm</code> command)	Host that issued the operation instruction
Free description	msg	<i>message</i>	Message that is output in the event of an alarm and execution of automatic action

Whether each fixed output item exists depends on the output timing. The following subsections describe the message ID and fixed output items for each output timing.

■ Startup and termination of PFM services (StartStop)

- Output host
Host on which the corresponding service is running
- Output component
Each service that starts and stops

A message ID and operation information are output when the PFM service starts and stops (StartStop). The following table lists and describes the message IDs and operation information that are output.

Table I–4: Message IDs and operation information that are output when a PFM service starts and stops (StartStop)

Item name	Attribute name	Value
Message ID	msgid	<ul style="list-style-type: none">• Start: KAVE03000-I is output.• Stop: KAVE03001-I is output.
Operation information	op	<ul style="list-style-type: none">• Start: Start is output.• Stop: Stop is output.

■ Startup and termination of the stand-alone mode (StartStop)

- Output host
PFM - RM host
- Output component
Remote Monitor Collector and Remote Monitor Store services

A message ID is output when the stand-alone mode starts and ends (StartStop). The following table lists and describes the message IDs that are output.

Table I–5: Message IDs that are output when the stand-alone mode starts and ends (StartStop)

Item name	Attribute name	Value
Message ID	msgid	<ul style="list-style-type: none">• Start of the stand-alone mode: KAVE03002-I is output.• End of the stand-alone mode: KAVE03003-I is output.

Note 1

Fixed output items are not output.

Note 2

When each service of PFM - RM for Platform starts, it connects to the PFM - Manager host to register node information and to acquire the most recent alarm definition information.

If the service cannot connect to the PFM - Manager host, it starts (in the stand-alone mode) with only some of the functions enabled (such as collection of operation information). KAVE03002-I is then issued in order to indicate that the service has started in the stand-alone mode.

Thereafter, the service continues to attempt to connect to the PFM - Manager host at specific intervals. When the service successfully registers node information and acquires definition information, it ends the stand-alone mode and KAVE03003-I is issued.

Output of KAVE03002-I and KAVE03003-I in the action logs indicates that PFM - RM for Platform was running in incomplete status.

■ Change to the status of the connection to PFM - Manager (ExternalService)

- Output host
PFM - RM host
- Output component
Remote Monitor Collector and Remote Monitor Store services

A message ID is output when the status of the connection to PFM - Manager changes (ExternalService). The following table lists and describes the message IDs that are output.

Table I-6: Message IDs that are output when the status of the connection to PFM - Manager changes (ExternalService)

Item name	Attribute name	Value
Message ID	msgid	<ul style="list-style-type: none">• Transmission of an event to PFM - Manager failed (queuing started): KAVE03300-I is output.• Re-transmission of an event to PFM - Manager was completed: KAVE03301-I is output.

Note 1

Fixed output items are not output.

Note 2

If transmission of an event to PFM - Manager fails, the Remote Monitor Collector service starts queuing events. Thereafter, each event is queued until the number of queued events reaches 3.

KAVE03300-I is output when event transmission fails and queuing starts. KAVE03301-I is output when connection with PFM - Manager is restored and transmission of queued events is completed.

Output of KAVE03300-I and KAVE03301-I in action logs brackets the period during which events were not transmitted to PFM - Manager in real time.

Note 3

The Remote Monitor Collector service normally sends events to PFM - Manager via the Remote Monitor Store service. If the Remote Monitor Store service is stopped for some reason, the Remote Monitor Collector service sends events to PFM - Manager directly.

KAVE03300-I is output when transmission of events to PFM - Manager fails. At this point, KAVE03301-I is not output because queuing has not started.

This action log indicates the events that were not sent to PFM - Manager.

■ Execution of automatic action (ManagementAction)

- Output host
Host that executed the action
- Output component
Action Handler service

When an automatic action is executed (ManagementAction), a message ID and free description item are output. The following table lists and describes the message IDs and free description items that are output.

Table I-7: Message IDs and free description items that are output during execution of an automatic action (ManagementAction)

Item name	Attribute name	Value
Message ID	msgid	<ul style="list-style-type: none">• Creation of a command execution process was successful: KAVE03500-I is output.• Creation of a command execution process failed: KAVE03501-W is output.• Email transmission was successful:

Item name	Attribute name	Value
Message ID	msgid	KAVE03502-I is output. • Email transmission failed: KAVE03503-W is output.
Free description	msg	• Command execution: cmd= <i>executed-command-line</i> is output. • Email transmission: mailto= <i>destination-email-address</i> is output.

Note

KAVE03500-I is output when a command execution process is created successfully. Thereafter, the result of checking for command execution and the execution results are not output to the action logs.

(4) Output example

The following shows an output example of action logs:

```
CALFHM 1.0, seqnum=1, msgid=KAVE03000-I, date=2007-01-18T22:46:49.682+09:00,
progid=JP1PFM, compid=7A1host01, pid=2076,
ocp:host=host01, ctgry=StartStop, result=Occurrence,
subj:pid=2076,op=Start
```

I.4 Action log output settings

Use the `jpccomm.ini` file to specify settings that enable output of action logs. If you do not specify these settings, action logs will not be output. This subsection describes how to specify the action log output settings and provides details about the `jpccomm.ini` file.

(1) How to specify the settings

To specify the action log output settings:

1. Stop all Performance Management services on the host.
2. Use a program such as a text editor to edit the `jpccomm.ini` file.
3. Save the `jpccomm.ini` file, and then close it.

(2) Details of the `jpccomm.ini` file

This subsection describes the `jpccomm.ini` file.

(a) Storage folder

The storage folder is *PFM-Manager-installation-folder*.

(b) Format

The following information is defined in the `jpccomm.ini` file:

- Whether action logs are to be output

- Action log output destination
- Number of action log files to be saved
- Size of the action log file

The specification format is as follows:

```
"item-name"=value
```

The following table lists and describes the settings to be specified in the `jpccomm.ini` file.

Table I–8: Settings specified in the `jpccomm.ini` file and their initial values

Item	Description
[Action Log Section]	Specifies the section name. This item cannot be changed.
Action Log Mode	<p>Specifies whether action logs are to be output. This item is mandatory.</p> <ul style="list-style-type: none"> • Initial value 0 (do not output) • Permitted values 0 (do not output), 1 (output) <p>If any other value is specified, an error message is output, in which case action logs are not output.</p>
Action Log Dir	<p>Specifies the output destination for action logs, using an absolute path.</p> <p>In a logical host environment, specify a directory on the shared disk.</p> <p>If the directory you specify is not on the shared disk, Performance Management will output action logs to each physical host that forms the basis for the logical host.</p> <p>If you specify a path that exceeds the maximum allowable length, or the system is unable to access the directory, an error message is output to the common log and Performance Management will not output action logs.</p> <ul style="list-style-type: none"> • Initial value: Omitted • Value used when this item is omitted (default): On physical hosts: - Windows: <i>installation-folder</i>\auditlog - UNIX: /opt/jplpc/auditlog/ On logical hosts: - Windows: <i>environment-directory</i>\jplpc\auditlog - UNIX: <i>environment-directory</i>/jplpc/auditlog • Available values: Character strings from 1 to 185 bytes in length
Action Log Num	<p>Specifies the maximum number of log files. This is the total number of current output file and shift files.</p> <ul style="list-style-type: none"> • Initial value Omitted • Value assumed when the item is omitted (default) 5 • Permitted values Integer in the range from 2 to 10 <p>If a nonnumeric character is specified, an error message is output and the value 5 (the default) is set.</p> <p>If the specified value is outside the permitted range, an error message is output and the integer in the range from 2 to 10 that is the closest to the specified value is set.</p>
Action Log Size	<p>Specifies the log file size in kilobytes.</p> <ul style="list-style-type: none"> • Initial value Omitted

Item	Description
Action Log Size	<ul style="list-style-type: none"> Value assumed when the item is omitted (default) 2,048 Permitted values Integer in the range from 512 to 2,096,128 <p>If a nonnumeric character is specified, an error message is output and a value of 2,048 (the default) is set. If the specified value is outside the permitted range, an error message is output and the integer in the range from 512 to 2,096,128 that is the closest to the specified value is set.</p>

J. Data Sources of Records

The individual fields of the records store values acquired from Performance Management and monitoring-target programs, as well as values computed using certain formulas and these acquired values. This appendix lists the sources of field values or formulas. The sources of field values and the formulas are collectively referred to as *data sources*.

J.1 Data sources of records (when the monitored host is running Windows)

This section describes the data sources for the field values when the monitored host is running Windows.

(1) Application Process Count (PD_APPC)

The following table lists the data sources for the individual fields of the Application Process Count (PD_APPC) record:

PFM - View name (PFM - Manager name)	Data source	
	Formula	WMI class
Record Type (INPUT_RECORD_TYPE)	--	--
Record Time (RECORD_TIME)	--	--
Interval (INTERVAL)	--	--
VA DeviceID (VADEVICEID)	--	--
Target Host (TARGET_HOST)	--	--
Polling Time (POLLING_TIME)	--	--
Target Host Time (TARGET_HOST_TIME)	C	C:Win32_OperatingSystem.LocalDateTime
Application Name (APPLICATION_NAME)	--	--
Monitoring Number (MONITORING_NUMBER)	--	--
Monitoring Label (MONITORING_LABEL)	--	--
Monitoring Min (MONITORING_MIN)	--	--
Monitoring Max (MONITORING_MAX)	--	--
Monitoring Count (MONITORING_COUNT)	--	--
Monitoring Status (MONITORING_STATUS)	--	--
Ext1 (EXT1)	--	--
Ext2 (EXT2)	--	--

Legend:

C: Indicates the value of a counter.

--: Indicates that no field value obtained by processing performance data is set.

(2) Application Process Detail (PD_APPD)

The following table lists the data sources for the individual fields of the Application Process Detail (PD_APPD) record:

PFM - View name (PFM - Manager name)	Data source	
	Formula	WMI class
Record Type (INPUT_RECORD_TYPE)	--	--
Record Time (RECORD_TIME)	--	--
Interval (INTERVAL)	--	--
VA DeviceID (VADEVICEID)	--	--
Target Host (TARGET_HOST)	--	--
Polling Time (POLLING_TIME)	--	--
Target Host Time (TARGET_HOST_TIME)	C	C:Win32_OperatingSystem.LocalDateTime
Application Name (APPLICATION_NAME)	--	--
Monitoring Number (MONITORING_NUMBER)	--	--
Monitoring Label (MONITORING_LABEL)	--	--
Monitoring Condition (MONITORING_CONDITION)	--	--
Monitoring Field (MONITORING_FIELD)	--	--
Monitoring Min (MONITORING_MIN)	--	--
Monitoring Max (MONITORING_MAX)	--	--
Monitoring Count (MONITORING_COUNT)	--	--
Monitoring Status (MONITORING_STATUS)	--	--
Ext1 (EXT1)	--	--
Ext2 (EXT2)	--	--

Legend:

C: Indicates the value of a counter.

--: Indicates that no field value obtained by processing performance data is set.

(3) Application Process Overview (PD_APS)

The following table lists the data sources for the individual fields of the Application Process Overview (PD_APS) record.

PFM - View name (PFM - Manager name)	Data source	
	Formula	WMI class
Record Type (INPUT_RECORD_TYPE)	--	--
Record Time (RECORD_TIME)	--	--
Interval (INTERVAL)	--	--
VA DeviceID (VADEVICEID)	--	--

Polling Time (POLLING_TIME)	--	--
Target Host Time (TARGET_HOST_TIME)	C	C:Win32_OperatingSystem.LocalDateTime
PID (PID)	C	C:Win32_PerfFormattedData_PerfProc_Process.IDProcess
Program Name (PROGRAM_NAME)	C	C:Win32_Process.Name
Parent PID (PARENT_PID)	C	C:Win32_PerfFormattedData_PerfProc_Process.CreatingProcessID
Command Line (COMMAND_LINE)	C	C:Win32_Process.CommandLine
Terminal (TERMINAL)	--	--
Elapsed Time (ELAPSED_TIME)	C	C:Win32_PerfFormattedData_PerfProc_Process.ElapsedTime
State (STATE)	--	--
Virtual Env ID (VIRTUAL_ENV_ID)	--	--
Ext1 (EXT1)	--	--
Ext2 (EXT2)	--	--

Legend:

C: Indicates the value of a counter.

--: Indicates that no field value obtained by processing performance data is set.

(4) Application Service Overview (PD_ASVC)

The following table lists the data sources for the individual fields of the Application Service Overview (PD_ASVC) record.

PFM - View name (PFM - Manager name)	Data source	
	Formula	WMI class
Record Type (INPUT_RECORD_TYPE)	--	--
Record Time (RECORD_TIME)	--	--
Interval (INTERVAL)	--	--
VA DeviceID (VADEVICEID)	--	--
Target Host (TARGET_HOST)	--	--

PFM - View name (PFM - Manager name)	Data source	
	Formula	WMI class
Polling Time (POLLING_TIME)	--	--
Target Host Time (TARGET_HOST_TIME)	C	C:Win32_OperatingSystem.LocalDateTime
Service Name (SERVICE_NAME)	C	C:Win32_Service.Name
Service Exit Code (SERVICE_EXIT_CODE)	C	C:Win32_Service.ServiceSpecificExitCode
Win32 Exit Code (WIN32_EXIT_CODE)	C	C:Win32_Service.ExitCode
Display Name (DISPLAY_NAME)	C	C:Win32_Service.DisplayName
State (STATE)	C	C:Win32_Service.State
Ext1 (EXT1)	--	--
Ext2 (EXT2)	--	--

Legend:

C: Indicates the value of a counter.

--: Indicates that no field value obtained by processing performance data is set.

(5) Application Summary (PD_APP2)

The following table lists the data sources for the individual fields of the Application Summary (PD_APP2) record.

PFM - View name (PFM - Manager name)	Data source	
	Formula	WMI class
Record Type (INPUT_RECORD_TYPE)	--	--
Record Time (RECORD_TIME)	--	--
Interval (INTERVAL)	--	--
VA DeviceID (VADEVICEID)	--	--
Target Host (TARGET_HOST)	--	--
Polling Time (POLLING_TIME)	--	--
Target Host Time (TARGET_HOST_TIME)	C	C:Win32_OperatingSystem.LocalDateTime
Application Name (APPLICATION_NAME)	--	--
Application Status (APPLICATION_STATUS)	--	--
Application Exist (APPLICATION_EXIST)	--	--
Virtual Env ID (VIRTUAL_ENV_ID)	--	--
Case Sensitive (CASE_SENSITIVE)	--	--

PFM - View name (PFM - Manager name)	Data source	
	Formula	WMI class
Ext1 (EXT1)	--	--
Ext2 (EXT2)	--	--

Legend:

C: Indicates the value of a counter.

--: Indicates that no field value obtained by processing performance data is set.

(6) Logical Disk Overview (PI_LDSK)

The following table lists the data sources for the individual fields of the Logical Disk Overview (PI_LDSK) record.

PFM - View name (PFM - Manager name)	Data source	
	Formula	WMI class
Record Type (INPUT_RECORD_TYPE)	--	--
Record Time (RECORD_TIME)	--	--
Interval (INTERVAL)	--	--
VA DeviceID (VADEVICEID)	--	--

Legend:

C: Indicates the value of a counter.

T: Indicates a time value.

TB: Indicates the time base value.

Δ : Indicates a value obtained by subtracting *previously collected value* from *current collected value*.

--: Indicates that no field value obtained by processing performance data is set.

J.2 Data sources of records (when the monitored host is running UNIX)

This section explains the data sources for the field values when the monitored host is running UNIX.

(1) Application Process Count (PD_APPC)

The following table lists the data sources for the individual fields of the Application Process Count (PD_APPC) record.

PFM - View name (PFM - Manager name)	Data source			
	HP-UX	Solaris	AIX	Linux
Record Type (INPUT_RECORD_TYPE)	--	--	--	--
Record Time (RECORD_TIME)	--	--	--	--
Interval (INTERVAL)	--	--	--	--
VA DeviceID (VADEVICEID)	--	--	--	--
Target Host (TARGET_HOST)	--	--	--	--
Polling Time (POLLING_TIME)	--	--	--	--
Target Host Time (TARGET_HOST_TIME)	date -u +%Y-%m-%dT%H:%M:%SZ	date -u +%Y-%m-%dT%H:%M:%SZ	date -u +%Y-%m-%dT%H:%M:%SZ	date -u +%Y-%m-%dT%H:%M:%SZ
Application Name (APPLICATION_NAME)	--	--	--	--
Monitoring Number (MONITORING_NUMBER)	--	--	--	--
Monitoring Label (MONITORING_LABEL)	--	--	--	--
Monitoring Min (MONITORING_MIN)	--	--	--	--
Monitoring Max (MONITORING_MAX)	--	--	--	--
Monitoring Count (MONITORING_COUNT)	--	--	--	--
Monitoring Status (MONITORING_STATUS)	--	--	--	--
Ext1 (EXT1)	--	--	--	--
Ext2 (EXT2)	--	--	--	--

Legend:

--: Indicates that no field value obtained by processing performance data is set.

(2) Application Process Detail (PD_APPD)

The following table lists the data sources for the individual fields of the Application Process Detail (PD_APPD) record.

PFM - View name (PFM - Manager name)	Data source			
	HP-UX	Solaris	AIX	Linux
Record Type (INPUT_RECORD_TYPE)	--	--	--	--
Record Time (RECORD_TIME)	--	--	--	--
Interval (INTERVAL)	--	--	--	--
VA DeviceID (VADEVICEID)	--	--	--	--
Target Host (TARGET_HOST)	--	--	--	--

PFM - View name (PFM - Manager name)	Data source			
	HP-UX	Solaris	AIX	Linux
Polling Time (POLLING_TIME)	--	--	--	--
Target Host Time (TARGET_HOST_TIME)	date -u +%Y-%m-%dT%H:%M:%SZ	date -u +%Y-%m-%dT%H:%M:%SZ	date -u +%Y-%m-%dT%H:%M:%SZ	date -u +%Y-%m-%dT%H:%M:%SZ
Application Name (APPLICATION_NAME)	--	--	--	--
Monitoring Number (MONITORING_NUMBER)	--	--	--	--
Monitoring Label (MONITORING_LABEL)	--	--	--	--
Monitoring Condition (MONITORING_CONDITION)	--	--	--	--
Monitoring Field (MONITORING_FIELD)	--	--	--	--
Monitoring Min (MONITORING_MIN)	--	--	--	--
Monitoring Max (MONITORING_MAX)	--	--	--	--
Monitoring Count (MONITORING_COUNT)	--	--	--	--
Monitoring Status (MONITORING_STATUS)	--	--	--	--
Ext1 (EXT1)	--	--	--	--
Ext2 (EXT2)	--	--	--	--

Legend:

--: Indicates that no field value obtained by processing performance data is set.

(3) Application Process Overview (PD_APS)

The following table lists the data sources for the individual fields of the Application Process Overview (PD_APS) record.

PFM - View name (PFM - Manager name)	Data source			
	HP-UX	Solaris	AIX	Linux
Record Type (INPUT_RECORD_TYPE)	--	--	--	--
Record Time (RECORD_TIME)	--	--	--	--
Interval (INTERVAL)	--	--	--	--

Δ : Indicates a value obtained by subtracting *previously collected value* from *current collected value*.

--: Indicates that no field value obtained by processing performance data is set.

K. Linkage to JP1/SLM

Linkage to JP1/SLM can enhance the operation status monitoring performed by PFM - RM for Platform.

To make it easier to monitor on JP1/SLM, PFM - RM for Platform provides PFM - Manager with default monitoring items for JP1/SLM.

The table below shows the default monitoring items that PFM - RM for Platform provides to PFM - Manager.

For multi-instance records, records matching the value specified for the key are collected. To see the key used for the collection target, check the collection result for each record.

For `Effective Free Memory`, 0 is output in Windows, AIX, HP-UX, and Solaris. For `Network Bytes`, 0 is output in UNIX.

Table K–1: Default monitoring items PFM - RM for Platform provides to PFM - Manager

Display name in JP1/SLM	Explanation	Record (record ID)	Key (PFM-Manager name)	Field name
CPU Usage	Process's CPU usage (%)	System Summary (PI)	--	CPU_PERCENT
Available Memory	Total size of unused physical memory (megabytes)	System Summary (PI)	--	FREE_MEM_MBYTES
Effective Free Memory	Size of unused physical memory that applications can actually use (megabytes)	System Summary (PI)	--	EFFECTIVE_FREE_MEM_MBYTES
Logical Disk Free Size	Size of unused area (megabytes)	Logical Disk Overview (PI_LDsk)	ID (ID)	FREE_MBYTES
Disk Busy %	Percentage of time the disk was busy when a loading or writing request was received (%)	Physical Disk Overview (PI_PDSK)	ID (ID)	BUSY_PERCENT
Network Bytes	Rate at which data is sent or received through the network interface (bytes/second)	Network Interface Overview (PI_NET)	ID (ID)	TOTAL_BYTES_PER_SEC
Network Packets	Rate at which packets are sent or received through the network interface (packets/second)	Network Interface Overview (PI_NET)	ID (ID)	TOTAL_PACKETS_PER_SEC

Legend:

--: Not applicable

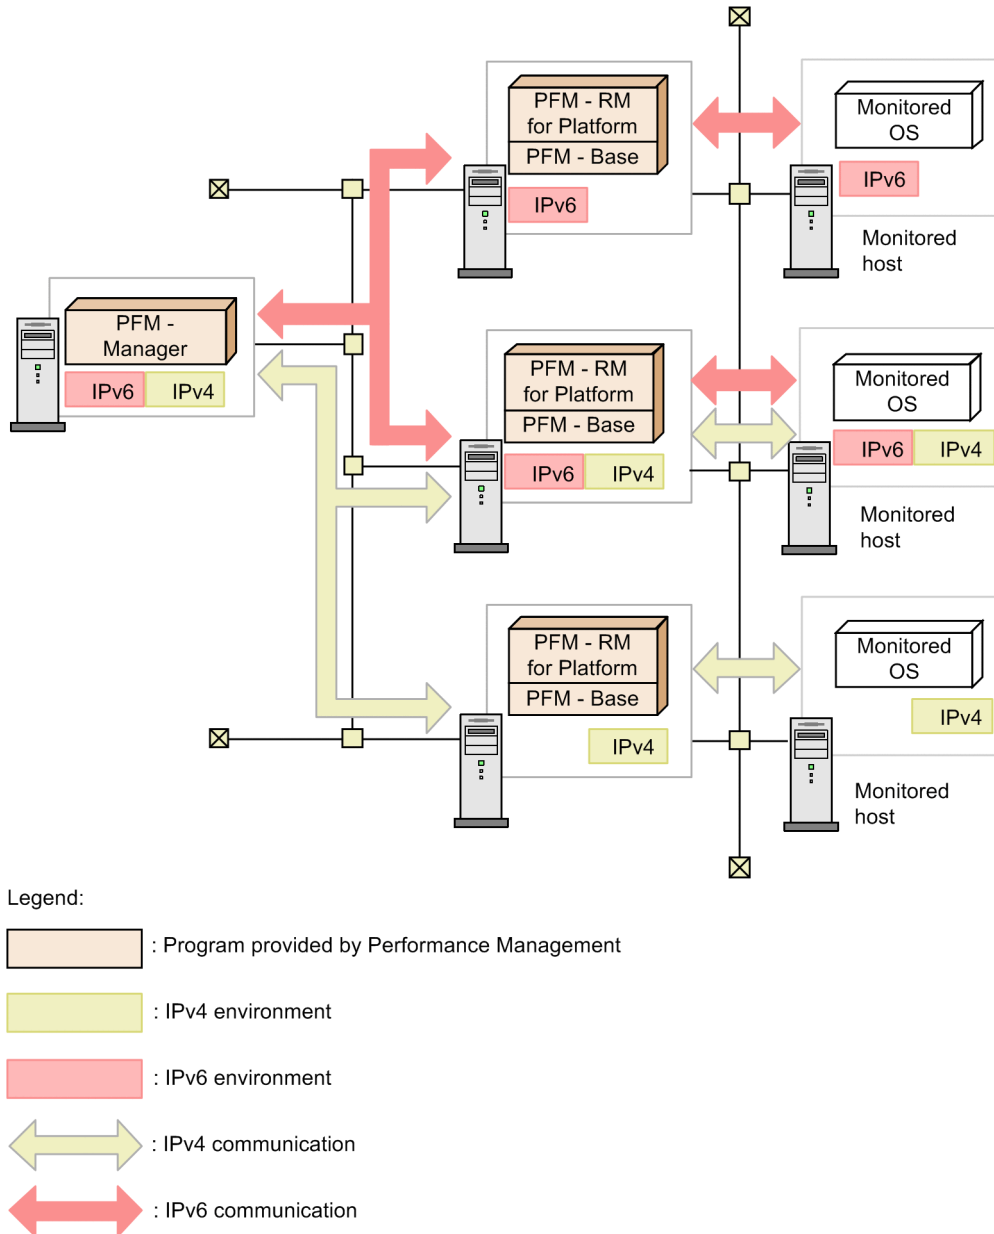

To implement these default monitoring items in PFM - Manager, you must copy the setup file and execute the setup command. For details, see [3.1.4 Setup procedure for the Windows edition](#) or [3.2.4 Setup procedure for the UNIX edition](#).

L. Communication in IPv4 and IPv6 Environments

Performance Management supports both IPv4 and IPv6 network environments. Therefore, you can run Performance Management even in a network environment where IPv4 and IPv6 coexist.

However, this applies only when the OS of the hosts on which PFM - RM for Platform and PFM - Manager are installed is Windows or Linux.

Figure L–1: Scope to which communication in IPv4 and IPv6 environments applies

To enable communication in an IPv6 environment, you must execute the `jpcconf ipv6 enable` command. For details about this command, see the chapter that describes commands in the manual *JP1/Performance Management Reference*. For details about the conditions and timing for executing the `jpcconf ipv6 enable` command, see the chapter that describes an example of a network configuration that includes an IPv6 environment in the *JP1/Performance Management Planning and Configuration Guide*.

M. Version Changes

This appendix presents the changes in the manuals for each version.

M.1 Changes in 11-10

(1) Changes in the manual (3021-3-A42-10(E))

- The following OS is now supported as a monitored OS:
 - AIX V7.2
- The function to remotely monitor the operating statuses of hosts that support the ICMP protocol (health check monitoring) was added.
- The following OSs are now supported:
 - Microsoft(R) Windows Server(R) 2016 Datacenter
 - Microsoft(R) Windows Server(R) 2016 Standard
- An explanation was added about the port numbers used for WMI.
- The following property was added to the instance environment setting items for PFM - RM for Platform (for Windows):
 - `Use_Processor_Information_Object`
- An explanation was added about the action to take when the following problem occurs:
 - The message `KAVL17016-WPerformance data was not saved to the Store database because it is the same as previous performance data . is output to the common message log.`
 - If the OS of the monitored host is UNIX, a timeout occurs when collecting performance data.

M.2 Changes in 11-00

(1) Changes from the manual (3021-3-047-10(E)) to the manual (3021-3-A42(E))

- The following OSs are no longer supported:
PFM - Manager and PFM - Web Console
 - Microsoft(R) Windows Server(R) 2003
 - Microsoft(R) Windows Server(R) 2008 (except R2)
 - AIX 6 (32-bit)
 - AIX 7 (32-bit)
 - HP-UX 11i V3 (IPF)
 - Red Hat Enterprise Linux(R) 5 (x86)
 - Red Hat Enterprise Linux(R) 5 (AMD/Intel 64)
 - Red Hat Enterprise Linux(R) 5 Advanced Platform (AMD/Intel 64)

- Red Hat Enterprise Linux(R) 5 Advanced Platform (x86)
- Red Hat Enterprise Linux(R) Server 6 (32-bit x86)
- Solaris 10

PFM - Base

- Microsoft(R) Windows Server(R) 2003
- Microsoft(R) Windows Server(R) 2008 (except R2)
- AIX 6 (32-bit)
- AIX 7 (32-bit)
- Red Hat Enterprise Linux(R) 5 (x86)
- Red Hat Enterprise Linux(R) 5 (AMD/Intel 64)
- Red Hat Enterprise Linux(R) Server 6 (32-bit x86)

PFM - RM for Platform

- Microsoft(R) Windows Server(R) 2003
- Microsoft(R) Windows Server(R) 2008 (except R2)
- Red Hat Enterprise Linux(R) 5 (x86)
- Red Hat Enterprise Linux(R) 5 (AMD/Intel 64)
- Red Hat Enterprise Linux(R) Server 6 (32-bit x86)
- The following OSs are now supported:
 - CentOS 6.1 (x64) or later
 - CentOS 7.1 or later
 - Red Hat Enterprise Linux(R) Server 7.1 or later
 - Oracle Linux(R) Operating System 6.1 (x64) or later
 - Oracle Linux(R) Operating System 7.1 or later
 - SUSE Linux(R) Enterprise Server 12
- Monitoring Console Https was added to the properties of the Agent Collector service.
- The product name was changed from JP1/ITSMLM to JP1/SLM.
- Linkage with Network Node Manager (NNM) was discontinued.
- ODBC-based application programs were discontinued.
- The following languages were added as languages available in Performance Management:
 - Korean
 - Spanish
 - Chinese (simplified characters)
 - German
 - French
 - Russian
- Logical hosts can now be specified as monitored hosts.
- The procedure for disabling UAC was added for monitored hosts running Windows Server 2008 or later.

(2) Changes from the manual (3021-3-350-10(E)) to the manual (3021-3-A42(E))

- The following OSs are no longer supported:

PFM - Manager and PFM - Web Console

- Microsoft(R) Windows Server(R) 2003
- Microsoft(R) Windows Server(R) 2008 (except R2)
- AIX 6 (32-bit)
- AIX 7 (32-bit)
- HP-UX 11i V3 (IPF)
- Red Hat Enterprise Linux(R) 5 (x86)
- Red Hat Enterprise Linux(R) 5 (AMD/Intel 64)
- Red Hat Enterprise Linux(R) 5 Advanced Platform (AMD/Intel 64)
- Red Hat Enterprise Linux(R) 5 Advanced Platform (x86)
- Red Hat Enterprise Linux(R) Server 6 (32-bit x86)
- Solaris 10

PFM - Base

- Microsoft(R) Windows Server(R) 2003
- Microsoft(R) Windows Server(R) 2008 (except R2)
- AIX 6 (32-bit)
- AIX 7 (32-bit)
- Red Hat Enterprise Linux(R) 5 (x86)
- Red Hat Enterprise Linux(R) 5 (AMD/Intel 64)
- Red Hat Enterprise Linux(R) Server 6 (32-bit x86)

PFM - RM for Platform

- Microsoft(R) Windows Server(R) 2003
- Microsoft(R) Windows Server(R) 2008 (except R2)
- Red Hat Enterprise Linux(R) 5 (x86)
- Red Hat Enterprise Linux(R) 5 (AMD/Intel 64)
- Red Hat Enterprise Linux(R) Server 6 (32-bit x86)

- The following OSs are now supported:

- CentOS 6.1 (x64) or later
- CentOS 7.1 or later
- Red Hat Enterprise Linux(R) Server 7.1 or later
- Oracle Linux(R) Operating System 6.1 (x64) or later
- Oracle Linux(R) Operating System 7.1 or later
- SUSE Linux(R) Enterprise Server 12

- The following products were added as monitoring agents:

- PFM - Agent for Cosminexus
- PFM - Agent for DB2
- PFM - Agent for Domino
- PFM - Agent for Exchange Server
- PFM - Agent for HiRDB
- PFM - Agent for IIS
- PFM - Agent for OpenTP1
- PFM - Agent for WebLogic Server
- PFM - Agent for WebSphere Application Server
- Monitoring Console Https was added to the properties of the Agent Collector service.
- The product name was changed from JP1/ITSMLM to JP1/SLM.
- Linkage with Network Node Manager (NNM) was discontinued.
- ODBC-based application programs were discontinued.
- The following languages were added as languages available in Performance Management:
 - Korean
 - Spanish
 - German
 - French
 - Russian
- Logical hosts can now be specified as monitored hosts.
- The procedure for disabling UAC was added for monitored hosts running Windows Server 2008 or later.

M.3 Changes in 10-50

Note: The changes include the functions that were supported from release 10-00 to release 10-50.

(1) Changes in the manual (3021-3-047-10(E))

- The following OSs are now supported:
 - Red Hat Enterprise Linux(R) 5 (AMD/Intel 64)
 - Red Hat Enterprise Linux(R) 5 Advanced Platform (AMD/Intel 64)
- The timing of performance data collection by the collection process was changed.
- The following OSs are now supported as monitoring targets:
 - CentOS 6(x64)
 - CentOS 6 (i386)
 - Oracle Linux(R) Operating System 6 (x64)
 - Oracle Linux(R) Operating System 6 (x86)
 - Solaris 11 (SPARC)
 - SUSE Linux Enterprise Server 11 (x86_64)

- SUSE Linux Enterprise Server 11 (x86)
- The common account information function is now supported.
- The unit used in the formula for estimating the agent log size was changed from kilobytes to megabytes.
- Information about the number of agent log files that can be collected per instance was added.
- Over 10 Sec Collection Time was added as a property related to the performance data collection conditions for each record.
- The following messages were added:
KAVL17028-E, KAVL17029-W to KAVL17033-W, KAVL17034-E, KAVL17035-W, KAVL17036-W
- The following messages were changed:
KAVL17005-E, KAVL17017-W, KAVL17022-W, KAVL17023-W, KAVL17026-W
- The following files were added to agent logs:
 - collect_core_nn
 - timer_core_nn
- The agent log output method was changed from the wrap-around method to a sequential method.
- A formula for estimating the amount of disk space used by agent logs per instance was added.
- The following properties for multiple monitoring were added:
 - PrimaryManager
 - Secondary Manager
- Realtime Report Data Collection Mode was added as a property that is used when historical data collection takes priority over real-time report display processing.
- The following files were added:
 - suspended.dat
 - *monitoring-target-name_suspended.dat*

(2) Changes in the manual (3021-3-350-10(E))

Note: The changes include the functions that were added between version 10-00 and version 10-50.

- The following OSs are now supported:
 - Red Hat Enterprise Linux(R) 5 (AMD/Intel 64)
 - Red Hat Enterprise Linux(R) 5 Advanced Platform (AMD/Intel 64)
- The timing of performance data collection by the collection process was changed.
- The following OSs are now supported as monitoring targets:
 - CentOS 6(x64)
 - CentOS 6 (i386)
 - Oracle Linux(R) Operating System 6 (x64)
 - Oracle Linux(R) Operating System 6 (x86)
 - Solaris 11 (SPARC)
 - SUSE Linux Enterprise Server 11 (x86_64)
 - SUSE Linux Enterprise Server 11 (x86)

- The common account information function is now supported.
- The unit used in the formula for estimating the agent log size was changed from kilobytes to megabytes.
- Information about the number of agent log files that can be collected per instance was added.
- Over 10 Sec Collection Time was added as a property related to the performance data collection conditions for each record.
- The following messages were added:
KAVL17028-E, KAVL17029-W to KAVL17033-W, KAVL17034-E, KAVL17035-W, KAVL17036-W
- The following messages were changed:
KAVL17005-E, KAVL17017-W, KAVL17022-W, KAVL17023-W, KAVL17026-W
- The following files were added to agent logs:
 - `collect_core_nn`
 - `timer_core_nn`
- The agent log output method was changed from the wrap-around method to a sequential method.
- A formula for estimating the amount of disk space used by agent logs per instance was added.
- The following properties for multiple monitoring were added:
 - Primary Manager
 - Secondary Manager
- Realtime Report Data Collection Mode was added as a property that is used when historical data collection takes priority over real-time report display processing.
- The following files were added:
 - `suspended.dat`
 - `monitoring-target-name_suspended.dat`

M.4 Changes in 10-00

(1) Changes in the manual (3021-3-047(E))

- The following OSs were removed:
 - HP-UX 11i V2 (IPF)
 - Solaris 9 (SPARC)
 - AIX 5L V5.3
 - Red Hat Enterprise Linux(R) AS 4 (IPF)
 - Red Hat Enterprise Linux(R) AS 4 (AMD64 & Intel EM64T)
 - Red Hat Enterprise Linux(R) ES 4 (AMD64 & Intel EM64T)
 - Red Hat Enterprise Linux(R) AS 4 (x86)
 - Red Hat Enterprise Linux(R) ES 4 (x86)
- The following collection processes were added to enable WMI collection processing according to the OS type:
 - `jpc7corecollect32.exe` (32-bit edition)

- `jpc7corecollect64.exe` (64-bit edition)
- If the OS of the host where PFM - RM for Platform is installed is Windows Server 2008 R2 or Linux, performance data can now be collected even in an IPv6 environment.
- Process monitoring conditions can now be specified by using up to 4,096 bytes of data.
- The following default monitoring items are now available for PFM - Manager, making it possible for PFM - RM for Platform to link to JP1/ITSMLM:
 - `CPU_PERCENT`
 - `FREE_MEM_MBYTES`
 - `EFFECTIVE_FREE_MEM_MBYTES`
 - `FREE_MBYTES`
 - `BUSY_PERCENT`
 - `TOTAL_BYTES_PER_SEC`
 - `TOTAL_PACKETS_PER_SEC`

(2) Changes in the manual (3021-3-350(E))

- The following OSs are now supported:
 - HP-UX 11i V2 (IPF)
 - Solaris 9 (SPARC)
 - AIX 5L V5.3
 - Red Hat Enterprise Linux(R) AS 4 (IPF)
 - Red Hat Enterprise Linux(R) AS 4 (AMD64 & Intel EM64T)
 - Red Hat Enterprise Linux(R) ES 4 (AMD64 & Intel EM64T)
 - Red Hat Enterprise Linux(R) AS 4 (x86)
 - Red Hat Enterprise Linux(R) ES 4 (x86)
- The following collection processes were added to enable WMI collection processing according to the OS type:
 - `jpc7corecollect32.exe` (32-bite edition)
 - `jpc7corecollect64.exe` (64-bit edition)
- If the OS of the host where PFM - RM for Platform is installed is Windows Server 2008 R2, Windows Server 2012, or Linux, PFM - RM for Platform can collect performance data even in an IPv6 environment.
- The following default monitoring items are now available for PFM - Manager, making it possible for PFM - RM for Platform to link to JP1/ITSMLM:
 - `CPU_PERCENT`
 - `FREE_MEM_MBYTES`
 - `EFFECTIVE_FREE_MEM_MBYTES`
 - `FREE_MBYTES`
 - `BUSY_PERCENT`
 - `TOTAL_BYTES_PER_SEC`
 - `TOTAL_PACKETS_PER_SEC`

M.5 Changes in 09-50

(1) Changes in the manual (3020-3-R39-30(E))

- A function was added for monitoring a monitored host in a UNIX environment from a PFM - RM host in a Windows environment.
- A function was added for specifying collection of process operation status information by executing the `jpcprocdef create` command.
- An explanation was added about software and packages that must be installed when the monitored host is running UNIX.
- An explanation was added about the operation for distributing a public key to the monitored host by executing the `ssh-copy-id` command.
- The following files were added under the *installation-folder\agt7\agent\instance-name\targets\monitoring-target-name* folder to the list of folders and files when PFM - RM for Platform is running under Windows:
 - `records.stderr_NNNN`
 - `common.stdout_NNNN`
 - `common.stderr_NNNN`
 - `os.stdout_NNNN`
 - `os.stderr_NNNN`
 - `wmi.out_NNNN`
- An explanation was added about the function for synchronizing the agent information between the PFM - Manager host and the PFM - Web Console host by executing the `jpc tool service sync` command.
- The explanation for the Reason (REASON) field of the System Status (PD) record was changed due to the addition of the function for monitoring a monitored host in a UNIX environment from a PFM - RM host in a Windows environment.
- An explanation was added about cases in which performance data cannot be collected accurately.
- The following messages were added:
KAVL17023-W, KAVL17024-W, KAVL17025-W, KAVL17026-W
- The explanation for message KAVL17017-W was changed.
- An explanation was added about the action to take when the following problems occur:
 - The Remote Monitor Collector service of PFM - RM does not start.
 - Failure Audit (event ID: 4625 or 4776) is recorded in the Windows security event log.
- An explanation was added about the action to take when the value of the Status field of the PD record is ERROR and the Reason field shows one of the following values:
 - `Invalid environment (SSH_Client)`
 - `Invalid environment (Perl_Module)`
 - `Invalid environment (Private_Key_File)`
- An explanation was added about the action to take when the alarms related to process monitoring are not reported as intended.
- Windows firewall information that needs to be collected is now included in the OS log information.

- An explanation was added about information that needs to be collected by PuTTY and ActivePerl.
- The estimate on the amount of memory required was added.
- The following properties were added to the Remote Monitor Configuration - Remote Monitor directory of the Remote Monitor Collector service:
 - SSH_Client
 - Perl_Module
- The TargetType property was added to the Remote Monitor Configuration - Target directory of the remote agent and group agent of PFM - RM for Platform.
- The following files under the *installation-folder\agt7\dat* folder were added to the list of folders and files when PFM - RM for Platform is running under Windows:
 - common.dat
 - cmd2rec
 - cmd2rec_common
 - cmd2rec_OS
 - OS.dat
- A list of redistribution files for Microsoft(R) Visual C++(R) 2005 SP1 that need to be installed in the Windows Server 2003 environment was added.
- Versions of data models and monitoring template alarm tables were added for PFM - RM for Platform version 09-50.
- An explanation was added about the sources of record field values or formulas (data sources).

M.6 Changes in 09-10

(1) Changes in the manual (3020-3-R39-20(E))

- A function was added for monitoring process operation status.
- The following records were added due to the addition of the function for monitoring process operation status:
 - Application Process Count (PD_APPC)
 - Application Process Detail (PD_APPD)
 - Application Process Overview (PD_APS)
 - Application Service Overview (PD_ASVC)
 - Application Summary (PD_APP2)
- The following alarms were added due to the addition of the function for monitoring process operation status:
 - Application Status
 - Process Existence
 - Service Stop
 - Service Stop(dsp nm)
- The following reports were added due to the addition of the function for monitoring process operation status:
 - Application Process Count

- Application Process Status
- Application Status
- Windows Server 2008 is now supported.
- The setup command was changed so that it can be executed in non-interactive mode.
- `Ps_Category` was added to the instance environment settings of PFM - RM for Platform due to the addition of the function for monitoring process operation status.
- The `ps` command was added to the package (commands) required by a monitored host due to the addition of the function for monitoring process operation status.
- The version of the monitoring template alarm table was changed from 09.00 to 09.10.
- The following alarm tables were added due to the addition of the function for monitoring process operation status:
 - PFM RM Platform Template Alarms [PS] 09.10
 - PFM RM Platform Template Alarms [SVC] 09.10
 - PFM RM Platform Template Alarms [APP] 09.10
- Notes were added about collecting historical data.
- Estimates were added on the amount of memory and disk space required.
- The following logs are now included in the information that needs to be collected in the Windows environment:
 - WMI log
 - Message log during installation (for Windows Server 2008)
- The following directories were added to the remote agent and group agent properties due to the addition of the function for monitoring process operation status:
 - Application monitoring setting
 - ADDITION OR DELETION A SETTING
- The data model version was changed from 4.0 to 5.0.

N. Reference Material for This Manual

This appendix provides reference information, including various conventions, for this manual.

N.1 Related publications

This manual is part of a related set of manuals. The manuals in the set are listed below (with the manual numbers):

Manuals associated with JP1/Performance Management:

- *JP1 Version 11 Performance Management: Getting Started (Operation and Performance Management)* (3021-3-A36(E))
- *JP1 Version 11 JP1/Performance Management Planning and Configuration Guide* (3021-3-A37(E))
- *JP1 Version 11 JP1/Performance Management User's Guide* (3021-3-A38(E))
- *JP1 Version 11 JP1/Performance Management Reference* (3021-3-A39(E))
- *JP1 Version 11 JP1/Performance Management - Agent Option for Platform* (3021-3-A51(E)), for Windows systems
- *JP1 Version 11 JP1/Performance Management - Agent Option for Platform* (3021-3-A52(E)), for UNIX systems

Manuals associated with JP1:

- *Job Management Partner 1/Software Distribution Administrator's Guide Volume 1* (3020-3-S81(E)), for Windows systems
- *Job Management Partner 1/Software Distribution Client Description and User's Guide* (3020-3-S85(E)), for UNIX systems
- *Job Management Partner 1/Software Distribution SubManager Description and Administrator's Guide* (3020-3-L42(E))
- *Job Management Partner 1/Software Distribution Manager* (3000-3-841(E))

N.2 Conventions: Abbreviations for product names

This manual uses the following abbreviations for product names:

Abbreviation		Full name or meaning
AIX		AIX V6.1
		AIX V7.1
		AIX V7.2
HP-UX	HP-UX (IPF) or HP-UX 11i (IPF)	HP-UX 11i V3 (IPF)
JP1/Base		JP1/Base
JP1/IM	JP1/IM - Manager	JP1/Integrated Management - Manager

- *PFM - RM, PFM - Manager, PFM - Agent, PFM - Base, and PFM - Web Console* are sometimes collectively referred to as *Performance Management*.
- *HP-UX, Solaris, AIX, and Linux* are sometimes collectively referred to as *UNIX*.

[#]

This product operates only in a Japanese environment.

N.3 Conventions: Acronyms

This manual also uses the following acronyms:

Acronym	Full name or meaning
CPU	Central Processing Unit
CSV	Comma Separated Value

Acronym	Full name or meaning
DCOM	Distributed Component Object Model
DHCP	Dynamic Host Configuration Protocol
DMZ	DeMilitarized Zone
DNS	Domain Name System
FQDN	Fully Qualified Domain Name
GUI	Graphical User Interface
HTML	Hyper Text Markup Language
IP	Internet Protocol
IPF	Itanium(R) Processor Family
IPv4	Internet Protocol Version 4
IPv6	Internet Protocol Version 6
LAN	Local Area Network
NAPT	Network Address Port Translation
NAT	Network Address Translation
NIC	Network Interface Card
ODBC	Open Database Connectivity
OS	Operating System
PDF	Portable Document Format
RAM	Random Access Memory
RAS	Remote Access Service
SCM	Service Control Manager
SFTP	SSH File Transfer Protocol
SNMP	Simple Network Management Protocol
SSH	Secure Shell
TCP	Transmission Control Protocol
TCP/IP	Transmission Control Protocol/Internet Protocol
UAC	User Access Control
Web	World Wide Web
WMI	Windows Management Instrumentation
WPAR	Workload Partition

N.4 Notation for product names, service IDs, and service keys in this manual

In Performance Management, version 09-00 and later, enabling the product name display functionality allows you to display service IDs and service keys with product names.

Identifier	Product name display functionality	
	Disabled	Enabled
Service ID	TS1 <code>host-name</code>	<code>host-name</code> <RM Platform> (Store)
	TA1 <code>host-name</code>	<code>host-name</code> <RM Platform>
Service key	agt7	RMPlatform

In this manual, service IDs and service keys are shown in the formats that are in effect when the product name display functionality is enabled.

You can enable the product name display functionality only when both of the following conditions are satisfied:

- The version of the prerequisite program (PFM - Manager or PFM - Base) on the same device as PFM - RM for Platform is 09-00 or later.
- The versions of PFM - Web Console and PFM - Manager on the connection target are 09-00 or later.

N.5 Notation for folder path names in this manual

The default installation folders for the Windows edition of Performance Management are as follows. The *system-drive* \Program Files part is determined by the OS environment variable specified during installation and might differ according to the environment.

Default installation folder for PFM - Base

system-drive\Program Files (x86)\Hitachi\jplpc

In this manual, the installation folder of PFM - Base is shown as *installation-folder*.

Default installation folder for PFM - Manager

system-drive\Program Files (x86)\Hitachi\jplpc

Default installation folder for PFM - Web Console

system-drive\Program Files (x86)\Hitachi\jplpcWebCon

N.6 Conventions: KB, MB, GB, and TB

This manual uses the following conventions:

- 1 KB (kilobyte) is 1,024 bytes.
- 1 MB (megabyte) is 1,024² bytes
- 1 GB (gigabyte) is 1,024³ bytes.
- 1 TB (terabyte) is 1,024⁴ bytes.

O. Glossary

action

An operation that is executed automatically by Performance Management when data being monitored reaches a threshold. The following are the types of actions:

- Sending an email
- Executing a command
- Issuing an SNMP trap
- Issuing a JP1 event

Action Handler

One of the PFM - Manager or PFM - RM services. This service executes actions.

administration tool

Various commands and GUI functions that are used to check the service status and to manipulate performance data. It provides the following functions:

- Displaying the configuration and status of services
- Backing up and restoring performance data
- Exporting performance data to a text file
- Erasing performance data

agent

The PFM - RM service that collects performance data.

alarm

Information that defines an action to be executed and the event message to be sent when the data being monitored reaches a threshold.

alarm table

A table consisting of at least one alarm that defines the following information:

- Object to be monitored (such as Process, TCP, or WebService)
- Information to be monitored (such as the CPU usage rate or the number of bytes received per second)
- Condition to be monitored (such as a threshold value)

bind

Process of associating an alarm with an agent. When an alarm is bound to an agent, the user can be notified when the performance data collected by the agent reaches the threshold defined for the alarm.

cluster system

A system of multiple server systems that are linked to each other. The two types of cluster systems are a High Availability (HA) cluster system and a load-balancing cluster system.

An HA cluster system achieves high availability. Its purpose is to provide continuous operation even in the event of a failure. If a server fails during application processing, a standby server inherits the processing. This prevents the application from being interrupted in the event of a failure, thereby improving availability.

A load-balancing cluster system distributes the workload among multiple nodes in order to improve throughput. If a node stops due to a failure, this method can also improve availability by switching nodes so that processing can continue.

In this manual, *cluster system* refers to an HA cluster system.

common account information

Each PFM - RM host can centrally manage the account information that is common in multiple instance environments or on monitored targets. Common account information consists of `pfmhost` for instance environments, and `wmi` (for Windows) and `ssh` (for UNIX) for monitored targets.

Correlator

One of the PFM - Manager services. This service controls event transmission between services. When the Correlator checks an alarm status and determines that the threshold value has been exceeded, it sends an alarm event and an agent event to the Trap Generator service and to PFM - Web Console.

database ID

ID of a database that is added to each of PFM - RM's records. The database ID indicates the type of the records that are stored in the corresponding database. The following are the database IDs:

- **PI**
Indicates a database for records of the PI record type
- **PD**
Indicates a database for records of the PD record type

data model

A collective name for the records and fields of a PFM - RM. A data model is managed by its version.

drilldown report

A report that is associated with another report or with a field in a report. Use a drilldown report to display detailed or related information about a report.

executing node

The node executing jobs at one of the server systems that constitute a cluster system (node whose logical host is active).

failover

Inheritance in a cluster system of a server's job processing from the executing node to the standby node in the event of a failure.

field

Individual operating information included in records. Fields correspond to monitoring items in Performance Management. For example, monitoring items such as `CPU %` or `Page Faults/sec` in System Overview(PI) records correspond to fields.

function ID

A 1-byte identifier that indicates the function type of a Performance Management program service. This is part of the service ID.

health check monitoring

A function to remotely monitor the operating statuses of hosts and hardware equipment that support the ICMP protocol (can communicate through `ping`) by using the health check function of Performance Management.

historical report

A report indicating the status of a monitoring target from a point in time in the past to the current time.

instance

In this manual, the term *instance* is used as follows:

- When referring to the record format
Each row in a record is called an *instance*. A record consisting of a single row is called a *single-instance record*, while a record consisting of multiple rows is called a *multi-instance record*.
- When referring to the PFM - Agent and PFM - RM startup method
A single agent that monitors the target on the same host is called a *single-instance agent*. On the other hand, when the monitoring target supports multiple instances, an agent that monitors all instances of the monitoring target is called a *multi-instance agent*. Each agent constituting the multi-instance agent is called an *instance*.

instance number

An identifier indicating a 1-byte management number that is used for internal processing. An instance number is part of the service ID.

JP1/SLM

A product that helps maintain service levels by monitoring the performance of a business system as experienced by service users. Linking to JP1/SLM can enhance the operation status monitoring performed by PFM - RM for Platform.

lifetime

The period over which consistency of the performance data collected in a record is guaranteed.

Master Manager

One of the PFM - Manager services. This is PFM - Manager's main service.

Master Store

One of the PFM - Manager services. This service manages the alarm events issued from each PFM - Agent or PFM - RM. The Master Store service uses a database to retain event data.

monitored host

A host that is monitored by PFM - RM for Platform.

monitoring template

Predefined alarms and reports provided by PFM - RM. The monitoring template simplifies preparations for monitoring the operation status of PFM - RM because the user does not have to create complex definitions.

multi-instance record

A record consisting of multiple rows. Multi-instance records have unique ODBC key fields.

See *instance*.

multiple monitoring

An operation where a duplicate monitoring manager is employed. This eliminates the downtime in monitoring and increases the availability of the system.

Name Server

One of the PFM - Manager services. This service manages service configuration information in the system.

non-interactive (commands)

A mode of executing commands in which user entries required for the execution of commands are provided by means of specification of options or by reading from a definition file rather than by prompting the user to enter responses.

Executing commands non-interactively reduces the burden on the user by helping to automate the installation of the operation monitoring system.

ODBC key field

A primary key required for PFM - Manager or PFM - Base to use the record data stored in a Store database. Some ODBC key fields are common to all records and some are specific to individual records.

PD record type

See *Product Detail record type*.

performance data

Data collected from a monitored system about the operation status of its resources.

Performance Management

A collective name for a group of software programs that are provided for monitoring and analyzing issues related to system performance. Performance Management consists of the following five program products:

- PFM - Manager
- PFM - Web Console
- PFM - Base
- PFM - Agent
- PFM - RM

PFM - Agent

One of the program products constituting Performance Management. PFM - Agent is equivalent to the system monitoring facility. There are various PFM - Agents according to the application being monitored, database, and OS. PFM - Agent provides the following functions:

- Monitoring the performance of the monitoring target
- Collecting and recording data on the monitoring target

PFM - Base

One of the program products constituting Performance Management. It provides Performance Management with the basic operation-monitoring functions. PFM - Base is required in order to run PFM - Agent and PFM - RM. PFM - Base provides the following functions:

- Administrative tools, including various commands
- Common functions needed for linkage between Performance Management and other systems

PFM - Manager

One of the program products constituting Performance Management. PFM - Manager is equivalent to the manager facility and provides the following functions:

- Management of the Performance Management program products
- Management of events

PFM - Manager name

A field name that is specified in SQL statements to access field data in a Store database when SQL is used with PFM - Manager.

A name used to identify a field in a Store database. This name is used to specify fields in commands.

PFM - RM

One of the program products constituting Performance Management. PFM - RM is equivalent to the system monitoring facility. One PFM - RM can monitor multiple targets. There are various PFM - RMs according to the application being monitored, database, and OS. PFM - RM provides the following functions:

- Monitoring the performance of remote monitoring targets
- Collecting and recording data on the monitoring targets

PFM - RM host

A host on which PFM - RM for Platform is installed.

PFM - View name

An alias of the PFM - Manager name. PFM - View names are more intuitive than the PFM - Manager names. For example, a field has the PFM - Manager name `INPUT_RECORD_TYPE`, while its PFM - View name is Record Type. The PFM - View name is used to specify a field using GUI on PFM - Web Console.

PFM - Web Console

One of the program products constituting Performance Management. PFM - Web Console is a browser and provides a Web application server function for achieving central monitoring of the Performance Management system. PFM - Web Console provides the following functions:

- Display of GUI windows
- Integrated monitoring and management
- Definition of reports and alarms

physical host

The environment that is unique to each server constituting a cluster system. A physical host environment is not inherited to any other server even in the event of failover.

PI record type

See *Product Interval record type*.

PL record type

See *Product Log record type*.

primary manager

A manager in a multiple-monitoring configuration, which is prioritized to communicate with monitoring agents (PFM - Agent and PFM - RM).

Product Detail record type

A type of record that stores performance data about the system status at a specific point in time, such as information about the hosts that are being monitored currently. Use the PD record type to obtain the system status at a specific point in time, such as the following:

- System's operation status
- Capacity of the current file system in use

product ID

A 1-byte identifier indicating the Performance Management program product to which a Performance Management program service belongs. This is part of the service ID.

Product Interval record type

A type of record that stores performance data obtained over a specific period of time (interval), such as the CPU usage rate every 5 minutes. Use the PI record type to analyze changes to or trends in the system status over time, such as the following:

- Changes in the number of system calls that are issued over a specific period of time
- Changes in the capacity of the file system being used

Product Log record type

A type of record that stores log information about a database or application being executed on a UNIX system.

real-time report

A report indicating the current status of a monitoring target.

record

A collection of operating information that is classified according to the purpose. For example, SystemOverview(PI) records are a collection of pieces of operating information that are used to provide a

system overview, such as CPU usage rates or the size of unused physical memory. Monitoring agents collect operating information by record. The records that can be collected differ according to the agent program.

Remote Monitor Collector

One of the PFM - RM services. This service collects performance data and evaluates performance data based on threshold values set for alarms.

Remote Monitor Store

One of the PFM - RM services. This service stores performance data. The Remote Monitor Store service uses a database to record performance data. There is a Remote Monitor Store service for each PFM - RM.

remote monitoring

A function for monitoring the operation status of a remote server from a separate host without having to install an agent at the monitored server.

report

A set of definitions for displaying performance data collected by PFM - RM in a graphical manner. It mainly contains definitions of the following information:

- Records to be displayed in the report
- Performance data items to be displayed
- Performance data display format (such as table or graph)

secondary manager

A manager in a multiple-monitoring configuration, which is not prioritized to communicate with monitoring agents (PFM - Agent and PFM - RM).

service ID

A unique ID that is added to each Performance Management program service. When a command is used to check the configuration of the Performance Management system or to back up individual agents' performance data, the service ID for the Performance Management program is specified in the command.

The format of the service ID depends on the settings for the product name display function. For details about the format of the service ID, see the chapter that describes the functions of Performance Management in the *JPI/Performance Management Planning and Configuration Guide*.

single-instance record

A record consisting of a single row. Single-instance records do not have a unique ODBC key field.

See [instance](#).

stand-alone mode

A status in which PFM - RM is running independently. Even if PFM - Manager's Master Manager and Name Server services cannot be started for a reason such as a failure, PFM - RM can be started independently to collect performance data.

standby node

The node at one of the server systems that constitute a cluster system that is in wait (standby) status so that it can inherit job processing in the event of a failure at the executing node.

See *instance*.

status management function

A function for managing the status of all services that are running on PFM - Manager and PFM - RM. The status management function enables appropriate error recovery actions to be taken promptly because the system administrator can obtain accurate start and stop status information for the services at each host.

Store database

A database in which performance data collected by the Remote Monitor Collector service is stored.

Trap Generator

One of the PFM - Manager services. This service issues SNMP traps.

workgroup

A unit for monitoring processes executed by PFM - RM for Platform. A workgroup can be specified in the following units:

- Windows users
- Windows groups
- Programs executed by a process
