

**JP1 Version 13**

**JP1/Integrated Management 3 - Manager  
Command, Definition File and API Reference**

**3021-3-L06-30(E)**

## Notices

### ■ Relevant program products

For details about the supported OS versions, and about the OS service packs and patches required by JP1/Integrated Management 3 - Manager and JP1/Integrated Management 3 - View, see the release notes for the relevant product.

*JP1/Integrated Management 3 - Manager (for Windows):*

P-2A2C-8EDL JP1/Integrated Management 3 - Manager 13-11

The above product includes the following:

P-CC2A2C-9MDL JP1/Integrated Management 3 - Manager 13-11 (for Windows Server 2022, Windows Server 2019, Windows Server 2016)

P-CC2A2C-6HDL JP1/Integrated Management 3 - View 13-00 (for Windows 11, Windows Server 2022, Windows Server 2019, Windows Server 2016, Windows 10)

P-CC2A2C-9GDL JP1/Integrated Management 3 - Agent 13-11 (for Windows Server 2022, Windows Server 2019, Windows Server 2016)

P-CC842C-9GDL JP1/Integrated Management 3 - Agent 13-11 (for Linux 9, Linux 8, Linux 7, Oracle Linux 9, Oracle Linux 8, Oracle Linux 7, SUSE Linux 15, SUSE Linux 12, Amazon Linux 2023)

P-CC2A2C-6LDL JP1/Base 13-10 (for Windows Server 2022, Windows Server 2019, Windows Server 2016)

P-CC842C-6LDL JP1/Base 13-10 (for Linux 9, Linux 8, Linux 7, Oracle Linux 9, Oracle Linux 8, Oracle Linux 7, SUSE Linux 15, SUSE Linux 12, Amazon Linux 2023)

P-CC1M2C-6LDL JP1/Base 13-10 (for AIX)

*JP1/Integrated Management 3 - Manager (for Linux):*

P-842C-8EDL JP1/Integrated Management 3 - Manager 13-11

The above product includes the following:

P-CC842C-9MDL JP1/Integrated Management 3 - Manager 13-11 (for Linux 9, Linux 8, Linux 7, Oracle Linux 9, Oracle Linux 8, Oracle Linux 7)

P-CC9W2C-9MDL JP1/Integrated Management 3 - Manager 13-11 (for SUSE Linux 15, SUSE Linux 12)

P-CC2A2C-6HDL JP1/Integrated Management 3 - View 13-00 (for Windows 11, Windows Server 2022, Windows Server 2019, Windows Server 2016, Windows 10)

P-CC2A2C-9GDL JP1/Integrated Management 3 - Agent 13-11 (for Windows Server 2022, Windows Server 2019, Windows Server 2016)

P-CC842C-9GDL JP1/Integrated Management 3 - Agent 13-11 (for Linux 9, Linux 8, Linux 7, Oracle Linux 9, Oracle Linux 8, Oracle Linux 7, SUSE Linux 15, SUSE Linux 12, Amazon Linux 2023)

P-CC2A2C-6LDL JP1/Base 13-10 (for Windows Server 2022, Windows Server 2019, Windows Server 2016)

P-CC842C-6LDL JP1/Base 13-10 (for Linux 9, Linux 8, Linux 7, Oracle Linux 9, Oracle Linux 8, Oracle Linux 7, SUSE Linux 15, SUSE Linux 12, Amazon Linux 2023)

P-CC1M2C-6LDL JP1/Base 13-10 (for AIX)

### ■ Trademarks

The company and product names mentioned in this document may be the trademarks of their respective owners.

This product includes software developed by the Apache Software Foundation (<http://www.apache.org/>).

This product includes software developed by Ben Laurie for use in the Apache-SSL HTTP server project.

Portions of this software were developed at the National Center for Supercomputing Applications (NCSA) at the University of Illinois at Urbana-Champaign.

This product includes software developed by the University of California, Berkeley and its contributors.

This software contains code derived from the RSA Data Security Inc. MD5 Message-Digest Algorithm, including various modifications by Spyglass Inc., Carnegie Mellon University, and Bell Communications Research, Inc (Bellcore).

Regular expression support is provided by the PCRE library package, which is open source software, written by Philip Hazel, and copyright by the University of Cambridge, England. The original software is available from <ftp://ftp.csx.cam.ac.uk/pub/software/programming/pcre/>

This product includes software developed by Ralf S.Engelschall <rse@engelschall.com> for use in the mod\_ssl project (<http://www.modssl.org/>).

1. This product includes software developed by the OpenSSL Project for use in the OpenSSL Toolkit. (<http://www.openssl.org/>)

2. This product includes cryptographic software written by Eric Young (eay@cryptsoft.com)

3. This product includes software written by Tim Hudson (tjh@cryptsoft.com)

4. This product includes the OpenSSL Toolkit software used under OpenSSL License and Original SSLeay License. OpenSSL License and Original SSLeay License are as follow:

#### LICENSE ISSUES

=====

The OpenSSL toolkit stays under a double license, i.e. both the conditions of the OpenSSL License and the original SSLeay license apply to the toolkit.

See below for the actual license texts. Actually both licenses are BSD-style Open Source licenses. In case of any license issues related to OpenSSL please contact [openssl-core@openssl.org](mailto:openssl-core@openssl.org).

## ■ Microsoft product name abbreviations

This manual uses the following abbreviations for Microsoft product names.

| Abbreviation | Full name or meaning                                                               |
|--------------|------------------------------------------------------------------------------------|
| Hyper-V      | Microsoft <sup>(R)</sup> Windows Server <sup>(R)</sup> 2012 Hyper-V <sup>(R)</sup> |
| SCVMM        | Microsoft <sup>(R)</sup> System Center Virtual Machine Manager 2012                |
| Windows 10   | Windows <sup>(R)</sup> 10 Enterprise 64-bit                                        |

| Abbreviation        | Full name or meaning                                                   |
|---------------------|------------------------------------------------------------------------|
|                     | Windows <sup>(R)</sup> 10 Home 64-bit                                  |
|                     | Windows <sup>(R)</sup> 10 Pro 64-bit                                   |
| Windows 11          | Windows <sup>(R)</sup> 11 Enterprise                                   |
|                     | Windows <sup>(R)</sup> 11 Home                                         |
|                     | Windows <sup>(R)</sup> 11 Pro                                          |
| Windows Server 2016 | Microsoft <sup>(R)</sup> Windows Server <sup>(R)</sup> 2016 Datacenter |
|                     | Microsoft <sup>(R)</sup> Windows Server <sup>(R)</sup> 2016 Standard   |
| Windows Server 2019 | Microsoft <sup>(R)</sup> Windows Server <sup>(R)</sup> 2019 Datacenter |
|                     | Microsoft <sup>(R)</sup> Windows Server <sup>(R)</sup> 2019 Standard   |
| Windows Server 2022 | Microsoft <sup>(R)</sup> Windows Server <sup>(R)</sup> 2022 Datacenter |
|                     | Microsoft <sup>(R)</sup> Windows Server <sup>(R)</sup> 2022 Standard   |

*Windows* is often used generically to refer to Windows 11, Windows Server 2022, Windows Server 2019, Windows Server 2016, Windows 10.

| <p>Added Microsoft SQL Server monitoring function (SQL exporter) to performance monitoring function by JP1/IM - Agent.</p> <p>Accordingly, the following definition files was added.</p> <ul style="list-style-type: none"> <li>SQL exporter metric definition file</li> <li>SQL exporter defaults collection metric defined file</li> <li>SQL exporter discovery configuration file</li> <li>SQL exporter configuration file</li> </ul> <p>The explanation was added to the following definition files.</p> <ul style="list-style-type: none"> <li>Prometheus configuration file</li> <li>Alert configuration file</li> </ul> <p>Service definition file</p>  | <i>2.1, SQL exporter metric definition file (metrics_sql_exporter.conf),<br/>SQL exporter default collection metric definition file (mssql_standard.collector.yml),<br/>SQL exporter discovery configuration file (jpc_file_sd_config_mssql.yml),<br/>SQL exporter configuration file (jpc_sql_exporter.yml),<br/>Alert configuration file (jpc_alerting_rules.yml)</i> |
| <p>Added the following functions for dashboard definitions:</p> <ul style="list-style-type: none"> <li>Dashboard import/export functions</li> <li>Dashboard get/list collection/deletion function for administrators</li> </ul> <p>Accordingly, explanations were added to the Intelligent Integrated Management Base definition file.</p> <p>In addition, the following API were added.</p> <ul style="list-style-type: none"> <li>Get Dashboard Definition API</li> <li>Get Dashboard Definitions List API</li> <li>Add Dashboard Definition API</li> <li>Delete Dashboard Definition API</li> </ul> <p>Also, the dashboard definition object was added.</p> | <i>Intelligent Integrated Management Base definition file (imdd.properties), 5.1, 5.20.1, 5.20.2, 5.20.3, 5.20.4, 7.2.6(1)</i>                                                                                                                                                                                                                                          |
| <p>For stable operation, OSS corresponding to add-on administration function enabled OSS wrapper to automatically restart service processes on a regular basis.</p> <p>Accordingly, explanation of the definition content for the service of OSS corresponding to the add-on management function was added to the following definition file.</p> <ul style="list-style-type: none"> <li>Service definition file</li> <li>Unit definition file</li> </ul> <p>Additionally, the environment-variable IMA_OSSWRAPPER_RESTART_INTERVAL (the interval at which OSS wrapper restarts OSS processes) was added.</p>                                                   | <i>Service definition file (jpc_program-name_service.xml),<br/>Unit definition file (jpc_program-name.service)</i>                                                                                                                                                                                                                                                      |

In addition to the above changes, minor editorial corrections were made.

## Preface

This manual describes the commands, definition files and API of JP1/Integrated Management 3 - Manager, JP1/Integrated Management 3 - View, and JP1/Integrated Management 3 - Agent systems. In this manual, JP1/Integrated Management is abbreviated to *JP1*, and JP1/Integrated Management 3 - Manager, JP1/Integrated Management 3 - View, and JP1/Integrated Management 3 - Agent are generically referred to as *JP1/Integrated Management* or *JP1/IM*. In addition, in this manual, read JP1/Integrated Management - Manager, JP1/Integrated Management - View, and JP1/Integrated Management - Agent as JP1/Integrated Management 3 - Manager, JP1/Integrated Management 3 - View, and JP1/Integrated Management 3 - Agent, respectively.

### ■ Intended readers

This manual is intended for users who want to manage, use, and operate an infrastructure that manages an open-platform system form JP1/IM. More specifically, it is intended for:

- System administrators who manage, use, and operate JP1/IM to centrally monitor the events that arise in the system.
- System administrators who manage, use, and operate JP1/IM to centrally monitor the status of the system management infrastructure based on correlation with events that arise in the system
- Those who have knowledge of operating systems and applications

### ■ Organization of this manual

This manual consists of the following chapters:

#### 1. *Commands*

Chapter 1 describes the syntax for the commands that can be used in JP1/Integrated Management.

#### 2. *Definition Files*

Chapter 2 describes the formats and syntax of the definition files for JP1/Integrated Management.

#### 3. *JP1 Events*

Chapter 3 describes the types and attributes of the JP1 events that are issued by JP1/Integrated Management.

#### 4. *User-created Plug-ins*

JP1/IM - Manager (Intelligent Integrated Management Base) can execute processing by using user-created plug-ins, which will be described in detail in this chapter.

#### 5. *API*

Chapter 5 describes the APIs provided by JP1/Integrated Management.

#### 6. *Customization of Integrated Operation Viewer Window*

Chapter 6 describes how to display a user-defined window when a specific IM management node is selected in the Integrated Operation Viewer window.

#### 7. *Information Necessary to Use the Intelligent Integrated Management Base*

Chapter 7 describes the SIDs and json objects that are necessary to use the Intelligent Integrated Management Base, the adapter command information that is necessary to use user-created plug-ins, and

the functionality provided to generate an IM management node tree. It also provides a sample plug-in and details regarding the control characters.

#### 8. Lists of System-Monitoring Objects (for Central Scope)

Chapter 8 describes the system-monitoring objects that are provided by JP1/Integrated Management.

#### 9. Monitoring Tree Models (for Central Scope)

Chapter 9 describes the structures of monitoring trees that are created automatically.

## ■ Manual suite

JP1/IM manuals provide necessary information according to the phase in the system life cycle (the phases include planning/design, configuration, and operation). Read the manual appropriate for the purpose.

The following figure explains which phases the JP1/IM manuals provide information for.

## ■ Conventions: Diagrams

This manual uses the following conventions in diagrams:

## ■ Conventions: Fonts and symbols

The following table explains the text formatting conventions used in this manual:

| Text formatting | Convention                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Bold</b>     | <p>Bold characters indicate text in a window, other than the window title. Such text includes menus, menu options, buttons, radio box options, or explanatory labels. For example:</p> <ul style="list-style-type: none"> <li>From the <b>File</b> menu, choose <b>Open</b>.</li> <li>Click the <b>Cancel</b> button.</li> <li>In the <b>Enter name</b> entry box, type your name.</li> </ul>                                                                                                                      |
| <i>Italic</i>   | <p>Italic characters indicate a placeholder for some actual text to be provided by the user or system. For example:</p> <ul style="list-style-type: none"> <li>Write the command as follows:<br/><code>copy source-file target-file</code></li> <li>The following message appears:<br/>A file was not found. (file = <i>file-name</i>)</li> </ul> <p>Italic characters are also used for emphasis. For example:</p> <ul style="list-style-type: none"> <li>Do <i>not</i> delete the configuration file.</li> </ul> |
| Monospace       | <p>Monospace characters indicate text that the user enters without change, or text (such as messages) output by the system. For example:</p> <ul style="list-style-type: none"> <li>At the prompt, enter <code>dir</code>.</li> <li>Use the <code>send</code> command to send mail.</li> <li>The following message is displayed:<br/><code>The password is incorrect.</code></li> </ul>                                                                                                                            |

The following table explains the symbols used in this manual:

| Symbol | Convention                                                                                                                                                                                                                                                                                                                                       |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | In syntax explanations, a vertical bar separates multiple items, and has the meaning of OR.<br>For example:<br>A   B   C means A, or B, or C.                                                                                                                                                                                                    |
| { }    | In syntax explanations, curly brackets indicate that only one of the enclosed items is to be selected.<br>For example:<br>{ A   B   C } means only one of A, or B, or C.                                                                                                                                                                         |
| [ ]    | In syntax explanations, square brackets indicate that the enclosed item or items are optional.<br>For example:<br>[A] means that you can specify A or nothing.<br>[B   C] means that you can specify B, or C, or nothing.                                                                                                                        |
| . . .  | In coding, an ellipsis ( . . . ) indicates that one or more lines of coding have been omitted.<br>In syntax explanations, an ellipsis indicates that the immediately preceding item can be repeated as many times as necessary. For example:<br>A, B, B, . . . means that, after you specify A, B, you can specify B as many times as necessary. |
| Δ      | Indicates a space.<br>Δ <sub>0</sub> : Zero or more spaces (space can be omitted).<br>Δ <sub>1</sub> : One or more spaces (space cannot be omitted).                                                                                                                                                                                             |
| ▲      | Indicates a tab.<br>Example:<br>▲ A means that a tab character precedes A.                                                                                                                                                                                                                                                                       |

## ■ Conventions: Installation folders for the Windows version of JP1/IM and JP1/Base

In this manual, the installation folders for the Windows versions of JP1/IM and JP1/Base are indicated as follows:

| Product name     | Installation folder | Default installation folder <sup>#</sup>               |
|------------------|---------------------|--------------------------------------------------------|
| JP1/IM - View    | <i>View-path</i>    | <i>system-drive</i> : \Program Files\Hitachi\JP1CoView |
| JP1/IM - Manager | <i>Manager-path</i> | <i>system-drive</i> : \Program Files\Hitachi\JP1IMM    |
|                  | <i>Console-path</i> | <i>system-drive</i> : \Program Files\Hitachi\JP1Cons   |
|                  | <i>Scope-path</i>   | <i>system-drive</i> : \Program Files\Hitachi\JP1Scope  |
| JP1/IM - Agent   | <i>Agent-path</i>   | <i>system-drive</i> : \Program Files\Hitachi\JP1IMA    |
| JP1/Base         | <i>Base-path</i>    | <i>system-drive</i> : \Program Files\Hitachi\JP1Base   |

<sup>#</sup>: Represents the installation folder when the product is installed in the default location. The location represented by *system-drive*: \Program Files is determined at the time of installation by an OS environment variable, and might differ depending on the environment.

## ■ Conventions: Meaning of "Administrator permissions" in this manual

In this manual, *Administrator permissions* refers to the Administrator permissions for the local PC. Provided that the user has Administrator permissions for the local PC, operations are the same whether they are performed with a local user account, a domain user account, or in an Active Directory environment.

## ■ Conventions: Version numbers

The version numbers of Hitachi program products are usually written as two sets of two digits each, separated by a hyphen. For example:

- Version 1.00 (or 1.0) is written as 01-00.
- Version 2.05 is written as 02-05.
- Version 2.50 (or 2.5) is written as 02-50.
- Version 12.25 is written as 12-25.

The version number might be shown on the spine of a manual as *Ver. 2.00*, but the same version number would be written in the program as *02-00*.

## ■ Conventions: Paths specified in definition files

A definition cannot include any file name that is specified with a network path.

For example, the event guide information file must have `EV_FILE` specified with a folder path that is not a network path.

## ■ Online manuals

JP1/IM comes with an HTML manual that you can read in a web browser.

The HTML manual has the same contents as this manual.

To view the HTML manual:

- In JP1/IM - View, choose **Help** and then **Help Contents**.
- In Integrated Operation Viewer Window, choose **Help** and then **Online manual**.

*Note:*

- If you use the **Start** menu, the HTML manual may be displayed in an existing browser window, depending on the related setting in the OS.

## ■ Output destinations of Integrated trace log file

Starting with JP1/IM 12-10, all 32-bit Java processes for JP1/IM have been changed to 64-bit Java processes. Therefore, the integrated trace log output destination output by the Java process function of each function of JP1 / IM is changed.

The following is the destination of the integrated trace log for each JP1/IM function from version 12-10 or later. If you are using the log file trap function, you must change the settings as you change the destination.

Output destinations of Integrated trace log file (32 bit): *system-drive\Program Files (x86)\Hitachi\HNTRLib2\spool*

- IM database
- Central Scope Service
- Process management

- Command execution
- Automatic action
- Installation and Setup

Output destinations of Integrated trace log file (64 bit): *system-drive*\Program Files\Hitachi\HNTRLib2\spool

- Event base service
- Central Console viewer
- Central Scope viewer
- Event Generation Service
- IM Configuration Management
- IM Configuration Management viewer
- Intelligent Integrated Management Base

## 2 Definition Files 414

- 2.1 List of definition files 415
- 2.2 Format of definition file 427

|     |                                                                                    |     |
|-----|------------------------------------------------------------------------------------|-----|
|     | ◆ Format of definition file explanations                                           | 427 |
|     | ◆ Definition files for displaying user-defined event attributes                    | 427 |
|     | ◆ Details of statements in definition files                                        | 432 |
|     | ◆ About definition of common placeholders for descriptive items in yml file        | 436 |
|     | ◆ Note on PromQL expression                                                        | 436 |
| 2.3 | JP1/IM - Manager definition files (JP1/IM - Manager)                               | 439 |
|     | ◆ Common definition settings file (changing the attribute of JP1 events)           | 439 |
|     | ◆ Operation log definition file (imm_operationlog.conf)                            | 440 |
| 2.4 | JP1/IM - Manager definition files (Intelligent Integrated Management Base)         | 443 |
|     | ◆ Intelligent Integrated Management Base definition file (imdd.properties)         | 443 |
|     | ◆ System node definition file (imdd_systemnode.conf)                               | 452 |
|     | ◆ Category name definition file for IM management nodes (imdd_category_name.conf)  | 460 |
|     | ◆ Target host definition file for configuration collection (imdd_target_host.conf) | 462 |
|     | ◆ Host name definition file (imdd_host_name.conf)                                  | 464 |
|     | ◆ IM management node link definition file (imdd_nodeLink_def.conf)                 | 466 |
|     | ◆ Suggestion definition file (imdd_suggestion.conf)                                | 471 |
|     | ◆ Single sign-on mapping definition file (imdd_sso_mapping.properties)             | 513 |
|     | ◆ Auto response action definition file (autoactconf.json)                          | 515 |
|     | ◆ Response action state monitoring definition file (responseactionnotice.conf)     | 516 |
|     | ◆ User-created definition file list definition file (imdd_user_deffile_list.json)  | 518 |
|     | ◆ Definition file properties file (imdd_file_properties.json)                      | 522 |
| 2.5 | JP1/IM - Manager definition files (Central Console)                                | 524 |
|     | ◆ Event-source-host mapping definition file (user_hostmap.conf)                    | 524 |
|     | ◆ Automated action environment definition file (action.conf.update)                | 530 |
|     | ◆ Automated action definition file (actdef.conf)                                   | 534 |
|     | ◆ Automated action definition file (actdef.conf) (for conversion)                  | 554 |
|     | ◆ Automatic action notification definition file (actnotice.conf)                   | 568 |
|     | ◆ Extended startup process definition file (jp1co_service.conf)                    | 573 |
|     | ◆ IM parameter definition file (jp1co_param_V7.conf)                               | 575 |
|     | ◆ System profile (.system)                                                         | 577 |
|     | ◆ User profile (defaultUser   profile_user-name)                                   | 579 |
|     | ◆ Communication environment definition file (console.conf.update)                  | 583 |
|     | ◆ Health check definition file (jcohc.conf)                                        | 585 |
|     | ◆ Event guide information file (jco_guide.txt)                                     | 589 |
|     | ◆ Status event definition file (processupdate.conf)                                | 597 |
|     | ◆ Correlation event generation system profile (egs_system.conf)                    | 598 |
|     | ◆ Correlation event generation definition file                                     | 601 |

- ◆ Correlation event generation environment definition file 623
- ◆ Definition file for manually registering incidents (incident.conf) 624
- ◆ Configuration file for incident inheritance information (incident\_info.conf) 626
- ◆ Severity changing definition file (jcochsev.conf) 631
- ◆ Command button definition file (cmdbtn.conf) 639
- ◆ File that defines which items are displayed for event conditions (attr\_list.conf) 644
- ◆ Configuration file for converting information (event\_info\_replace.conf) 647
- ◆ Item file 650
- ◆ Environment definition file for event report output (evtreport.conf) 653
- ◆ Filter file 654
- ◆ System color definition file (systemColor.conf) 659
- ◆ Definition file for extended event attributes 662
- ◆ Definition file for extended event attributes (extended file) 673
- ◆ Definition file for object types 679
- ◆ Common-exclusion-conditions extended definition file 681
- ◆ Common-exclusion-conditions display item definition file (common\_exclude\_filter\_attr\_list.conf) 694
- ◆ Common-exclusion-conditions auto-input definition file (common\_exclude\_filter\_auto\_list.conf) 696
- ◆ Display item definition file for the repeated event condition (event\_storm\_attr\_list.conf) 698
- ◆ Auto-input definition file for the repeated event condition (event\_storm\_auto\_list.conf) 701
- ◆ Display item definition file for the severity change definition (chsev\_attr\_list.conf) 703
- ◆ Auto-input definition file for the severity change definition (chsev\_auto\_list.conf) 705
- ◆ Definition file for opening monitor windows 708
- ◆ Email environment definition file (jimmail.conf) 714
- ◆ Display message change definition file (jcochmsg.conf) 722
- ◆ Display item definition file for a display message change definition (chmsg\_attr\_list.conf) 736
- ◆ Automatic input definition file for a display message change definition (chmsg\_auto\_list.conf) 738
- ◆ Environment definition file for events after the display message is changed (chmsgsevent.conf) 741
- 2.6 JP1/IM - Manager definition files (Central Scope) 743
  - ◆ Host information file (jcs\_hosts) 743
  - ◆ Guide information file (jcs\_guide.txt) 744
  - ◆ Settings file for the maximum number of status change events (evhist\_warn\_event\_xxx.conf) 749
  - ◆ Settings file for the completed-action linkage function (action\_complete\_xxx.conf) 751
  - ◆ Definition file for automatic delete mode of status change event 752
  - ◆ Definition file for monitoring object initialization mode 752
  - ◆ Automatic backup and recovery settings file for the monitoring object database (auto\_dbbackup\_xxx.conf) 753

|      |                                                                                                                         |     |
|------|-------------------------------------------------------------------------------------------------------------------------|-----|
|      | ◆ Definition file for on memory mode of status change condition                                                         | 755 |
|      | ◆ System profile of Central Scope (jcs_sysprofile_xxx.def)                                                              | 755 |
| 2.7  | JP1/IM - Manager definition files (IM Configuration Management)                                                         | 761 |
|      | ◆ Apply-IM-configuration-method definition file (jp1cf_applyconfig.conf)                                                | 761 |
|      | ◆ Host input information file (host_input_data.csv)                                                                     | 762 |
|      | ◆ Collected host information file (host_collect_data.csv)                                                               | 765 |
|      | ◆ Profile management environment definition file (jp1cf_profile_manager.conf)                                           | 767 |
|      | ◆ Remote log trap environment definition file (jp1cf_remote_logtrap.conf)                                               | 768 |
|      | ◆ Remote-monitoring log file-trap action definition file                                                                | 770 |
|      | ◆ Remote-monitoring event log trap action-definition file                                                               | 775 |
| 2.8  | JP1/IM - Manager definition files (IM database)                                                                         | 782 |
|      | ◆ Setup information file (jimdbsetupinfo.conf)                                                                          | 782 |
|      | ◆ Cluster setup information file (jimdbclustersetupinfo.conf)                                                           | 785 |
| 2.9  | JP1/IM - Manager definition files (Intelligent Integrated Management Database)                                          | 790 |
|      | ◆ Intelligent Integrated Management Database setup information file (jimgnbdbsetupinfo.conf)                            | 790 |
|      | ◆ Cluster environment Intelligent Integrated Management Database setup information file (jimgnbdbclustersetupinfo.conf) | 793 |
|      | ◆ Intelligent Integrated Management Database configuration file (postgresql.conf)                                       | 797 |
| 2.10 | JP1/IM - Manager definition files (Product plug-ins of JP1/IM - Agent)                                                  | 800 |
|      | ◆ Node exporter metric definition file (metrics_node_exporter.conf)                                                     | 800 |
|      | ◆ Process exporter metric definition file (metrics_process_exporter.conf)                                               | 809 |
|      | ◆ Node exporter (service monitoring) metric definition file (metrics_node_exporter_service.conf)                        | 810 |
|      | ◆ Windows exporter metric definition file (metrics_windows_exporter.conf)                                               | 812 |
|      | ◆ Windows exporter (process monitoring) metric definition file (metrics_windows_exporter_process.conf)                  | 819 |
|      | ◆ Windows exporter (service monitoring) metric definition file (metrics_windows_exporter_service.conf)                  | 820 |
|      | ◆ Windows exporter (Hyper-V monitoring) metric definition file for host (metrics_windows_exporter_hyperv_host.conf)     | 822 |
|      | ◆ Windows exporter (Hyper-V monitoring) metric definition file for VM (metrics_windows_exporter_hyperv_vm.conf)         | 826 |
|      | ◆ Node exporter for AIX metric definition file (metrics_node_exporter_aix.conf)                                         | 828 |
|      | ◆ Blackbox exporter metric definition file (metrics_blackbox_exporter.conf)                                             | 834 |
|      | ◆ Yet another cloudwatch exporter metric definition file (metrics_ya_cloudwatch_exporter.conf)                          | 838 |
|      | ◆ Promitor metric definition file (metrics_promitor.conf)                                                               | 852 |
|      | ◆ Script exporter metric definition file (metrics_script_exporter.conf)                                                 | 862 |
|      | ◆ Fluentd metric definition file (metrics_fluentd.conf)                                                                 | 864 |
|      | ◆ OracleDB exporter metric definition file (metrics_oracledb_exporter.conf)                                             | 866 |
|      | ◆ OracleDB exporter default collection metric definition file (default-metrics.toml)                                    | 870 |

- ◆ Web exporter metric definition file (metrics\_web\_exporter.conf) 871
- ◆ VMware exporter metric definition file for host (metrics\_vmware\_exporter\_host.conf) 874
- ◆ VMware exporter metric definition file for VM (metrics\_vmware\_exporter\_vm.conf) 883
- ◆ SQL exporter metric definition file (metrics\_sql\_exporter.conf) 887
- ◆ SQL exporter default collection metric definition file (mssql\_standard.collector.yml) 901
- ◆ Container monitoring metric definition file (metrics\_kubernetes.conf) 902
- ◆ Any Prometheus trend name metric definition file (metrics\_any-Prometheus-trend-name.conf) 913
- ◆ User-specific metric definition file (metrics\_any-Prometheus-trend-name.conf) 914
- ◆ User-specific metric definition file (Promitor) (metrics\_any-Prometheus-trend-name.conf) 915
- ◆ User-specific metric definition file (container monitoring) (metrics\_any-Prometheus-trend-name.conf) 916
- ◆ AWS definition file (aws\_settings.conf) 917
- 2.11 JP1/IM - Manager definition files (JP1/IM agent management base) 920
  - ◆ imbase common configuration file (jpc\_imbasecommon.json) 920
  - ◆ imbase configuration file (jpc\_imbase.json) 922
  - ◆ imbaseproxy configuration file (jpc\_imbaseproxy.json) 925
- 2.12 JP1/IM - View definition files 928
  - ◆ Operation definition file of the IM Configuration Management - View (jcfview.conf) 928
  - ◆ Communication environment definition file (view.conf.update) 929
  - ◆ Communication environment definition file (tree\_view.conf.update) 931
  - ◆ Non-encryption communication host configuration file (nossllhost.conf) 933
  - ◆ IM-View settings file (tuning.conf) 935
  - ◆ Web page call definition file (hitachi\_jp1\_product-name.html) 937
  - ◆ Start program definition file (!JP1\_CS\_APP0.conf) 939
  - ◆ Toolbar definition file (!JP1\_CS\_FTOOL0.conf) 941
  - ◆ Icon operation definition file (!JP1\_CS\_FTREE0.conf) 942
  - ◆ Configuration file for monitoring tree 944
  - ◆ Definition file for executing applications 948
  - ◆ Definition file for the Tool Launcher window 951
  - ◆ System profile of the Central Scope viewer (system.conf) 955
  - ◆ Performance report display definition file (performance.conf) 957
- 2.13 JP1/IM - Agent definition files 959
  - ◆ Alertmanager configuration file (jpc\_alertmanager.yml) 959
  - ◆ Prometheus configuration file (jpc\_prometheus\_server.yml) 961
  - ◆ Alert configuration file (jpc\_alerting\_rules.yml) 985
  - ◆ Node exporter discovery configuration file (jpc\_file\_sd\_config\_node.yml) 1053
  - ◆ Process exporter discovery configuration file (jpc\_file\_sd\_config\_process.yml) 1054

- ◆ Windows exporter discovery configuration file (jpc\_file\_sd\_config\_windows.yml) 1055
- ◆ Windows exporter (Hyper-V monitoring) discovery configuration file (jpc\_file\_sd\_config\_windows\_hyperv.yml) 1056
- ◆ Node exporter for AIX discovery configuration file (jpc\_file\_sd\_config\_node\_aix.yml) 1058
- ◆ Blackbox exporter (HTTP/HTTPS monitoring) discovery configuration file (jpc\_file\_sd\_config\_blackbox\_http.yml) 1059
- ◆ Blackbox exporter (ICMP monitoring) discovery configuration file (jpc\_file\_sd\_config\_blackbox\_icmp.yml) 1061
- ◆ Yet another cloudwatch exporter discovery configuration file (jpc\_file\_sd\_config\_cloudwatch.yml) 1063
- ◆ Promitor discovery configuration file (jpc\_file\_sd\_config\_promitor.yml) 1064
- ◆ OracleDB exporter discovery configuration file (jpc\_file\_sd\_config\_oracledb.yml) 1065
- ◆ Script exporter discovery configuration file (jpc\_file\_sd\_config\_script.yml) 1067
- ◆ Web exporter discovery configuration file (jpc\_file\_sd\_config\_web.yml) 1068
- ◆ Web scenario file (any-name.spec.ts) 1070
- ◆ VMware exporter discovery configuration file (jpc\_file\_sd\_config\_vmware.yml) 1071
- ◆ SQL exporter discovery configuration file (jpc\_file\_sd\_config\_mssql.yml) 1073
- ◆ User-specific discovery configuration file (user\_file\_sd\_config\_any-name.yml) 1075
- ◆ Service definition file (jpc\_program-name\_service.xml) 1078
- ◆ Unit definition file (jpc\_program-name.service) 1098
- ◆ Windows exporter configuration file (jpc\_windows\_exporter.yml) 1107
- ◆ Windows exporter (Hyper-V monitoring) configuration file (jpc\_windows\_exporter\_hyperv.yml) 1110
- ◆ Process exporter configuration file (jpc\_process\_exporter.yml) 1113
- ◆ Blackbox exporter configuration file (jpc\_blackbox\_exporter.yml) 1116
- ◆ Yet another cloudwatch exporter configuration file (jpc\_ya\_cloudwatch\_exporter.yml) 1123
- ◆ Promitor Scraper configuration file (metrics-declaration.yaml) 1128
- ◆ Promitor Scraper runtime configuration file (runtime.yaml) 1132
- ◆ Promitor Resource Discovery configuration file (resource-discovery-declaration.yaml) 1135
- ◆ Promitor Resource Discovery runtime configuration file (runtime.yaml) 1137
- ◆ Script exporter configuration file (jpc\_script\_exporter.yml) 1139
- ◆ Web exporter configuration file (jpc\_web\_exporter.yml) 1141
- ◆ Playwright configuration file (jpc\_playwright.config.ts) 1142
- ◆ VMware exporter configuration file (jpc\_vmware\_exporter.yml) 1150
- ◆ SQL exporter configuration file (jpc\_sql\_exporter.yml) 1153
- ◆ Sample file of Script exporter configuration file for SAP system monitoring (jpc\_script\_exporter\_sap.yml) 1157
- ◆ Log monitoring common definition file (jpc\_fluentd\_common.conf) 1160
- ◆ Log monitoring target definition file (jpc\_fluentd\_common\_list.conf) 1168

- ◆ Monitoring text-formatted log file definition file (fluentd\_@@@trapname@@\_tail.conf.template) 1170
- ◆ Windows event log monitoring definition file (fluentd\_@@@trapname@@\_wevt.conf.template) 1191
- ◆ Sample file of system log information monitoring definition file for SAP system (fluentd\_sap\_syslog\_tail.conf) 1198
- ◆ Sample file of CCMS alert information monitoring definition file for SAP system (fluentd\_sap\_alertlog\_tail.conf) 1203
- ◆ Environment parameters file for jr3slget command (jr3slget.ini) 1209
- ◆ Sample file of environment parameters file for jr3slget command (jr3slget.ini.sample) 1218
- ◆ Environment parameters file for jr3alget command (jr3alget.ini) 1220
- ◆ Sample file of environment parameters file for jr3alget command (jr3alget.ini.sample) 1228
- ◆ Log metrics definition file (fluentd\_any-name\_logmetrics.conf) 1230
- ◆ Property label definition file (property\_labels.conf) 1236
- ◆ imagent common configuration file (jpc\_imagentcommon.json) 1237
- ◆ imagent configuration file (jpc\_imagent.json) 1241
- ◆ imagentproxy configuration file (jpc\_imagentproxy.json) 1245
- ◆ imagentaction configuration file (jpc\_imagentaction.json) 1247
- ◆ User-created definition file list definition file (jpc\_user\_deffile\_list.json) 1249
- ◆ Definition file property file (jpc\_file\_properties.json) 1253
- ◆ Environment variable file (any file name) 1254
- ◆ Configuration file of the logical host new setup command (any-file-name) 1256
- ◆ Configuration file of the logical host version upgrade setup command (any-file-name) 1259

### **3 JP1 Events 1262**

- 3.1 Attributes of JP1 events 1263
  - 3.1.1 Basic attributes 1263
  - 3.1.2 Extended attributes 1264
- 3.2 JP1 events issued by JP1/IM 1266
  - 3.2.1 List of JP1 events issued by JP1/IM - Manager 1266
  - 3.2.2 Details of JP1 events output by JP1/IM - Manager 1283
  - 3.2.3 Lists of JP1 events output by JP1/IM - Agent 1404

### **4 User-created Plug-ins 1420**

- 4.1 What a user can do with the user-created plug-in 1421
  - 4.1.1 Format of the user-created plug-in 1421
- 4.2 Setting up and considering the management target 1423
  - 4.2.1 Adding a host 1423
  - 4.2.2 Considering the SID 1423
  - 4.2.3 Considering data labeled "value" of the SID 1424
- 4.3 Retrieving information from the management target 1426
  - 4.3.1 Collecting information with the adapter command 1426

|        |                                                                |      |
|--------|----------------------------------------------------------------|------|
| 4.3.2  | Retrieving information with the REST API                       | 1429 |
| 4.4    | Methods implemented in the plug-in                             | 1430 |
| 4.4.1  | Format of methods you can implement                            | 1430 |
| 4.4.2  | Implementation conventions of user-created plug-ins            | 1430 |
| 4.4.3  | Language conventions of user-created plug-ins                  | 1430 |
| 4.4.4  | List of methods                                                | 1431 |
| 4.4.5  | Exception handling                                             | 1456 |
| 4.5    | Methods available in the user-created plug-in                  | 1458 |
| 4.5.1  | jp1Imdd.callRest                                               | 1459 |
| 4.5.2  | jp1Imdd.readFile                                               | 1460 |
| 4.5.3  | jp1Imdd.encodeBase64                                           | 1461 |
| 4.5.4  | jp1SimtService.get                                             | 1461 |
| 4.5.5  | jp1SimtService.join                                            | 1461 |
| 4.5.6  | jp1SimtService.pack                                            | 1462 |
| 4.5.7  | jp1SimtService.packHost                                        | 1462 |
| 4.5.8  | jp1SimtService.parse                                           | 1463 |
| 4.5.9  | jp1Logger.trace                                                | 1463 |
| 4.5.10 | jp1Imdd.execCmd                                                | 1464 |
| 4.5.11 | jp1Imdd.getPluginConfDirPath                                   | 1467 |
| 4.5.12 | jp1Imdd.getVersion                                             | 1467 |
| 4.5.13 | jp1EmService.getEvent                                          | 1468 |
| 4.5.14 | jp1SimtService.getLink                                         | 1472 |
| 4.5.15 | jp1EmService.changeEventStatus                                 | 1474 |
| 4.5.16 | jp1SimtService.getTreeSid                                      | 1475 |
| 4.5.17 | jp1TrendDataService.getTrendData                               | 1476 |
| 4.5.18 | jp1TrendDataService.getLabelList                               | 1477 |
| 4.6    | File name and the storage location of the user-created plug-in | 1480 |
| 4.6.1  | Definition files used by user-created plug-ins                 | 1480 |
| 4.7    | Applying changes made to user-created plug-ins                 | 1482 |

## 5 API 1483

|       |                                     |      |
|-------|-------------------------------------|------|
| 5.1   | List of APIs                        | 1484 |
| 5.2   | API common specifications           | 1487 |
| 5.2.1 | Communication methods               | 1487 |
| 5.2.2 | Input/Output format                 | 1487 |
| 5.2.3 | Request format                      | 1487 |
| 5.2.4 | Limitation on the request body size | 1489 |
| 5.2.5 | Response format                     | 1490 |
| 5.2.6 | Error response message              | 1491 |
| 5.2.7 | Data types                          | 1492 |
| 5.2.8 | Authentication methods for REST API | 1493 |
| 5.3   | Explanation format for an API       | 1498 |

|        |                                                       |      |
|--------|-------------------------------------------------------|------|
| 5.4    | API for user authentication                           | 1499 |
| 5.4.1  | Login                                                 | 1499 |
| 5.4.2  | Logout                                                | 1501 |
| 5.4.3  | Initial secret issue                                  | 1502 |
| 5.4.4  | IM Client secret delete                               | 1503 |
| 5.4.5  | IM Client secret issue                                | 1505 |
| 5.4.6  | IM Client list acquisition                            | 1506 |
| 5.5    | API for link information                              | 1508 |
| 5.5.1  | Link information acquisition                          | 1508 |
| 5.5.2  | Link type list acquisition                            | 1513 |
| 5.6    | API for event management                              | 1515 |
| 5.6.1  | Event search                                          | 1515 |
| 5.6.2  | Event detailed information acquisition                | 1519 |
| 5.6.3  | Event status change                                   | 1521 |
| 5.6.4  | Event generation                                      | 1524 |
| 5.6.5  | JP1 Event converter                                   | 1529 |
| 5.7    | API for plug-ins                                      | 1533 |
| 5.7.1  | Plug-in processing execution                          | 1533 |
| 5.8    | API for system status monitoring                      | 1539 |
| 5.8.1  | IM management node related information generation     | 1539 |
| 5.8.2  | IM management node related information reflection     | 1541 |
| 5.8.3  | IM management node information acquisition            | 1544 |
| 5.8.4  | Configuration management tree information acquisition | 1546 |
| 5.8.5  | IM management node status acquisition                 | 1548 |
| 5.8.6  | Suggestion mapping information acquisition            | 1551 |
| 5.9    | API for proxy                                         | 1553 |
| 5.9.1  | Proxy credential setup                                | 1553 |
| 5.10   | API for linked product                                | 1556 |
| 5.10.1 | URL information acquisition                           | 1556 |
| 5.11   | API for trends                                        | 1558 |
| 5.11.1 | Metric list acquisition                               | 1558 |
| 5.11.2 | Time-series data acquisition                          | 1560 |
| 5.11.3 | Write Trend Data                                      | 1563 |
| 5.11.4 | Delete Trend Data                                     | 1565 |
| 5.12   | API for information management                        | 1570 |
| 5.12.1 | Version information acquisition                       | 1570 |
| 5.13   | Suggestion API                                        | 1572 |
| 5.13.1 | Previous execution history acquisition                | 1572 |
| 5.13.2 | Response action suggestion                            | 1574 |
| 5.13.3 | Response action execution                             | 1579 |
| 5.14   | OpenID authentication API                             | 1584 |

|          |                                                              |             |
|----------|--------------------------------------------------------------|-------------|
| 5.14.1   | Single sign-on mapping definition application                | 1584        |
| 5.15     | Distribution API                                             | 1586        |
| 5.15.1   | Get distribution (File download)                             | 1586        |
| 5.16     | API for Execute for Auto/Manual Response Action              | 1589        |
| 5.16.1   | Obtain execution result of Response Action                   | 1589        |
| 5.16.2   | Manual execution of Response Action                          | 1598        |
| 5.16.3   | Convert event-takeover info                                  | 1603        |
| 5.17     | API for definition file manipulation                         | 1608        |
| 5.17.1   | Get definition file list                                     | 1608        |
| 5.17.2   | Get definition file                                          | 1611        |
| 5.17.3   | Delete definition file                                       | 1613        |
| 5.17.4   | Updated definition file                                      | 1617        |
| 5.18     | API for Integrated agent Administration                      | 1622        |
| 5.18.1   | Retrieve integrated agent info                               | 1622        |
| 5.18.2   | Delete integrated agent info                                 | 1624        |
| 5.18.3   | Retrieve Secret List                                         | 1627        |
| 5.18.4   | Add, update, delete the secrets                              | 1629        |
| 5.19     | API for Lower manager Info Management                        | 1633        |
| 5.19.1   | Retrieve lower manager info list                             | 1633        |
| 5.19.2   | Add lower manager info                                       | 1634        |
| 5.19.3   | Delete lower manager info                                    | 1635        |
| 5.20     | Dashboard definition API                                     | 1638        |
| 5.20.1   | Get dashboard definition                                     | 1638        |
| 5.20.2   | Get dashboard definitions list                               | 1640        |
| 5.20.3   | Add dashboard definition                                     | 1642        |
| 5.20.4   | Delete dashboard definition                                  | 1644        |
| 5.21     | API for Prometheus server operation                          | 1646        |
| 5.21.1   | Reload Prometheus server                                     | 1646        |
| 5.21.2   | Prometheus server health check                               | 1647        |
| 5.22     | API for Alertmanager operation                               | 1649        |
| 5.22.1   | Reload Alertmanager                                          | 1649        |
| 5.22.2   | Alertmanager health check                                    | 1650        |
| 5.22.3   | Get silence list of Alertmanager                             | 1651        |
| 5.22.4   | Silence creation of Alertmanager                             | 1653        |
| 5.22.5   | Silence Revocation of Alertmanager                           | 1656        |
| 5.22.6   | Get silence of Alertmanager                                  | 1656        |
| 5.23     | API for Blackbox exporter operation                          | 1659        |
| 5.23.1   | Reload Blackbox exporter                                     | 1659        |
| 5.24     | API for scrape of Exporter used by JP1/IM - Agent            | 1661        |
| <b>6</b> | <b>Customization of Integrated Operation Viewer Window</b>   | <b>1664</b> |
| 6.1      | Overview of Integrated Operation Viewer Window customization | 1665        |

|       |                                                                                                     |      |
|-------|-----------------------------------------------------------------------------------------------------|------|
| 6.1.1 | What is customization of the Integrated Operation Viewer window?                                    | 1665 |
| 6.1.2 | The storage location                                                                                | 1665 |
| 6.1.3 | Notes                                                                                               | 1666 |
| 6.2   | Customization definition information of the Integrated Operation Viewer window                      | 1667 |
| 6.2.1 | Property information to be defined                                                                  | 1667 |
| 6.2.2 | Character string to be specified to <i>custom-UI-Id</i>                                             | 1669 |
| 6.2.3 | Description example of the Intelligent Integrated Management Base definition file (imdd.properties) | 1669 |
| 6.2.4 | Confirmation of the definition information                                                          | 1670 |
| 6.3   | Methods and objects that can be used in the user definition window                                  | 1671 |
| 6.3.1 | CustomContent.initialize                                                                            | 1671 |
| 6.3.2 | CustomContent.simt                                                                                  | 1673 |
| 6.3.3 | CustomContent.node                                                                                  | 1677 |
| 6.3.4 | CustomContent.options.props                                                                         | 1678 |
| 6.3.5 | CustomContent.postActions                                                                           | 1679 |
| 6.3.6 | CustomContent.showMessage                                                                           | 1679 |
| 6.3.7 | CustomContent.selectNodeByTreeSid                                                                   | 1679 |
| 6.3.8 | CustomContent.selectNodeByTargetSid                                                                 | 1680 |

## 7 Information Necessary to Use the Intelligent Integrated Management Base 1681

|       |                                             |      |
|-------|---------------------------------------------|------|
| 7.1   | SID                                         | 1682 |
| 7.1.1 | Configuration information SID               | 1682 |
| 7.1.2 | Tree SID                                    | 1686 |
| 7.1.3 | JP1 Event SID                               | 1688 |
| 7.1.4 | Information retrieved from each product     | 1688 |
| 7.2   | json objects                                | 1694 |
| 7.2.1 | Event                                       | 1694 |
| 7.2.2 | IM management node                          | 1703 |
| 7.2.3 | Trend Data Management                       | 1708 |
| 7.2.4 | Auto execution of response action           | 1711 |
| 7.2.5 | Integrated agent administration             | 1717 |
| 7.2.6 | Dashboard                                   | 1718 |
| 7.3   | Configuring the adapter command             | 1722 |
| 7.3.1 | Setting up the adapter command              | 1722 |
| 7.3.2 | Adapter command settings file               | 1723 |
| 7.4   | IM management node tree generation function | 1724 |
| 7.4.1 | System node generation function             | 1725 |
| 7.4.2 | Node generation function                    | 1726 |
| 7.4.3 | Tree SID conversion function                | 1729 |
| 7.5   | Sample plugin                               | 1732 |
| 7.5.1 | Assumed operation / configuration           | 1732 |

- 7.5.2 Example for the management node SID of the management tool A 1734
- 7.5.3 JP1 event issued by management tool A 1734
- 7.5.4 Sample plugin 1734
- 7.6 Control characters 1743

## **8 Lists of System-Monitoring Objects (for Central Scope) 1745**

- 8.1 About system-monitoring objects 1746
- 8.2 List of products for which system-monitoring objects are supported 1747
- 8.3 System-monitoring objects for JP1/AJS 1748
  - 8.3.1 AJS Monitoring system-monitoring object 1748
  - 8.3.2 Jobnet Monitoring (AJS) system-monitoring object 1749
- 8.4 System-monitoring objects for JP1/Cm2/SSO 1750
  - 8.4.1 Settings for monitoring system-monitoring objects for JP1/Cm2/SSO version 8 or earlier 1750
  - 8.4.2 SSO Monitoring system-monitoring object 1750
  - 8.4.3 Category Monitoring (SSO) system-monitoring object 1751
  - 8.4.4 Application Monitoring (SSO) system-monitoring object 1751
- 8.5 System-monitoring objects for JP1/PFM 1754
  - 8.5.1 Settings for monitoring system-monitoring objects for JP1/PFM 1754
  - 8.5.2 Agent Monitoring (PFM) system-monitoring object 1754
- 8.6 System-monitoring objects for JP1/PAM 1756
  - 8.6.1 Metric Monitoring (PAM) system-monitoring object 1756
  - 8.6.2 Object Monitoring (PAM) system-monitoring object 1756
- 8.7 System-monitoring objects for JP1/Software Distribution 1758
  - 8.7.1 SD Monitoring system-monitoring object 1758
  - 8.7.2 Distribution Job Monitoring (SD) system-monitoring object 1758
- 8.8 JP1/NNMi-type system-monitoring objects 1759
  - 8.8.1 Settings for monitoring system-monitoring objects for JP1/NNMi 1759
  - 8.8.2 NNMi Monitoring system-monitoring object 1759
  - 8.8.3 Node Monitoring (NNMi) system-monitoring object 1760
- 8.9 System-monitoring objects for HP NNM 1761
  - 8.9.1 NNM Monitoring system-monitoring object 1761
  - 8.9.2 Node Monitoring (NNM) system-monitoring object 1762
- 8.10 System-monitoring objects for JP1/IM - Manager 1763
  - 8.10.1 IM Monitoring system-monitoring object 1763
- 8.11 System-monitoring objects for Cosminexus 1764
  - 8.11.1 Logical Server Monitoring (Cosminexus) system-monitoring object 1764
  - 8.11.2 J2EE Application Monitoring (Cosminexus) system-monitoring object 1765
- 8.12 System-monitoring objects for HiRDB 1767
  - 8.12.1 Settings for monitoring system-monitoring objects for HiRDB 1767
  - 8.12.2 HiRDB Monitoring system-monitoring object 1767
- 8.13 System-monitoring objects for JP1/ServerConductor 1769
  - 8.13.1 Settings for monitoring system-monitoring objects for JP1/ServerConductor 1769

8.13.2 Physical Host Monitoring (System Manager) Monitoring system-monitoring object 1769

## **9 Monitoring Tree Models (for Central Scope) 1771**

9.1 Templates used to generate monitoring trees automatically 1772

9.2 Monitoring tree model for the work-oriented tree 1773

9.3 Monitoring tree model for the server-oriented tree 1775

## **Index 1777**

# 1

## Commands

This chapter describes the syntax of the commands that are used in JP1/IM.

## Format of command explanations

---

This section describes the format of the command explanations. Note that some of the items shown below might be omitted in some command explanations.

### Function

Describes the function of the command.

### Format

Describes the command's format.

### Execution permission

Describes the user permissions required in order to execute the command.

### Storage directory

Describes the command's storage location.

### Arguments

Describes the arguments of the command.

Note that arguments are case sensitive (except for the `ON` and `OFF` arguments, which are not case sensitive).

The `jpc_service` command and the `jpc_service_autostart` command `-on` and `-off` are case-sensitive.

### Notes

Provides additional important information about the command.

### Return values

Describes the command's return values.

For details about the messages that may be displayed during command execution, see the *JPI/Integrated Management 3 - Manager Messages*.

### Example

Provides an example of using the command.

### Example output

Provides an example of the output from execution of the command.

## Lists of commands

This section lists the names of the commands that can be used in JP1/IM and the permissions required to execute these commands. Note that the commands are described in alphabetical order from the next section.

### Legend and notes for tables

Whether a command is supported in the Windows and UNIX environments is indicated in the tables by the following notations and notes:

Legend:

Y: Supported

--: Not supported

#1

In Windows, a superuser means a user with Administrator permissions.

#2

This is a JP1/Base command (related to configuration definition and command execution) for the manager. For details about the command, see the chapter that describes commands in the *JP1/Base User's Guide*.

#3

In Windows, Administrator permissions are required. (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

#4

This command is used by the monitored AIX host.

### Commands related to startup, termination, and setup

| Overview of function                                          | Command name                           | Windows | UNIX | Required execution permission |
|---------------------------------------------------------------|----------------------------------------|---------|------|-------------------------------|
| Sets up JP1/IM - Manager (Central Console)                    | <i>jp1cc_setup (UNIX only)</i>         | --      | Y    | Superuser                     |
| Sets up JP1/IM - Manager (Central Scope)                      | <i>jp1cs_setup (UNIX only)</i>         | --      | Y    | Superuser                     |
| Starts JP1/IM - Manager automatically                         | <i>jco_start (UNIX only)</i>           | --      | Y    | Superuser                     |
| Terminates JP1/IM - Manager automatically                     | <i>jco_stop (UNIX only)</i>            | --      | Y    | Superuser                     |
| Displays the status of JP1/IM - Manager processes             | <i>jco_spmc_status</i>                 | Y       | Y    | Superuser <sup>#1</sup>       |
| Updates the status of JP1/IM - Manager processes              | <i>jco_spmc_reload</i>                 | Y       | Y    | Superuser <sup>#1</sup>       |
| Specifies settings required for operation in a cluster system | <i>jp1cohassetup (Windows only)</i>    | Y       | --   | Superuser <sup>#1</sup>       |
|                                                               | <i>jp1cshasetup (Windows only)</i>     | Y       | --   | Superuser <sup>#1</sup>       |
|                                                               | <i>jp1cc_setup_cluster (UNIX only)</i> | --      | Y    | Superuser                     |
|                                                               | <i>jp1cs_setup_cluster (UNIX only)</i> | --      | Y    | Superuser                     |
| Starts JP1/IM - Manager in a cluster system                   | <i>jco_start.cluster (UNIX only)</i>   | --      | Y    | Superuser                     |

| Overview of function                                                                 | Command name                              | Windows | UNIX | Required execution permission |
|--------------------------------------------------------------------------------------|-------------------------------------------|---------|------|-------------------------------|
| Terminates JP1/IM - Manager in a cluster system                                      | <i>jco_stop.cluster</i><br>(UNIX only)    | --      | Y    | Superuser                     |
| Forcibly terminates JP1/IM - Manager in a cluster system                             | <i>jco_killall.cluster</i><br>(UNIX only) | --      | Y    | Superuser                     |
| Specifies dependencies between JP1/IM-Manager Service and the JP1/Base Event service | <i>SpmSetSvcCon</i><br>(Windows only)     | Y       | --   | Superuser <sup>#1</sup>       |

## Commands related to IM databases

| Overview of function                                                                            | Command name         | Windows | UNIX | Required execution permission |
|-------------------------------------------------------------------------------------------------|----------------------|---------|------|-------------------------------|
| Sets up the IM Configuration Management database for storing configuration information          | <i>jcfdbsetup</i>    | Y       | Y    | Superuser <sup>#1</sup>       |
| Cancels setup of the IM Configuration Management database that stores configuration information | <i>jcfdbunsetup</i>  | Y       | Y    | Superuser <sup>#1</sup>       |
| Sets up an integrated monitoring database for storing JP1 events                                | <i>jcodbsetup</i>    | Y       | Y    | Superuser <sup>#1</sup>       |
| Cancels setup of the integrated monitoring database that stores JP1 events                      | <i>jcodbunsetup</i>  | Y       | Y    | Superuser <sup>#1</sup>       |
| Outputs to a CSV file JP1 event information registered in the integrated monitoring database    | <i>jcoevtreport</i>  | Y       | Y    | Superuser <sup>#1</sup>       |
| Backs up the IM database                                                                        | <i>jimdbbackup</i>   | Y       | Y    | Superuser <sup>#1</sup>       |
| Releases free area (free page area) in the IM Configuration Management database                 | <i>jimdbreclaim</i>  | Y       | Y    | Superuser <sup>#1</sup>       |
| Restores (recovers) a database from a backup that has been stored                               | <i>jimdbrecovery</i> | Y       | Y    | Superuser <sup>#1</sup>       |
| Reorganizes fragmented free space in a database                                                 | <i>jimdbbrorg</i>    | Y       | Y    | Superuser <sup>#1</sup>       |
| Checks the operating status of the IM database (such as running or stopped)                     | <i>jimdbstatus</i>   | Y       | Y    | Superuser <sup>#1</sup>       |
| Terminates the IM database                                                                      | <i>jimdbstop</i>     | Y       | Y    | Superuser <sup>#1</sup>       |
| Updates the IM database                                                                         | <i>jimdbupdate</i>   | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands related to IM Configuration Management

| Overview of function                                                                                                             | Command name       | Windows | UNIX | Required execution permission |
|----------------------------------------------------------------------------------------------------------------------------------|--------------------|---------|------|-------------------------------|
| Collects virtualization configuration information from HCSM, and outputs it to the virtualization configuration information file | <i>jcfcolvmhcs</i> | Y       | Y    | Superuser <sup>#1</sup>       |
| Collects virtualization configuration information from KVM, and outputs it to the virtualization configuration information file  | <i>jcfcolvmkvm</i> | Y       | Y    | Superuser <sup>#1</sup>       |

| Overview of function                                                                                                                                                                                                                                                                                                                                                                                                           | Command name                              | Windows | UNIX | Required execution permission |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|---------|------|-------------------------------|
| Collects virtualization configuration information from SCVMM, and outputs it to the virtualization configuration information file                                                                                                                                                                                                                                                                                              | <i>jfccolvmcvm</i><br>(Windows only)      | Y       | --   | Superuser <sup>#1</sup>       |
| Collects virtualization configuration information from vCenter, and outputs it to the virtualization configuration information file                                                                                                                                                                                                                                                                                            | <i>jfccolvmvc</i>                         | Y       | Y    | Superuser <sup>#1</sup>       |
| Collects virtualization configuration information from Hitachi Compute Blade logical partitioning feature, and outputs it to the virtualization configuration information file                                                                                                                                                                                                                                                 | <i>jfccolvmvirtage</i>                    | Y       | Y    | Superuser <sup>#1</sup>       |
| Acquires virtualization configuration information from VMware ESX and outputs it to a virtualization configuration information file                                                                                                                                                                                                                                                                                            | <i>jfccolvmesx</i>                        | Y       | Y    | Superuser <sup>#1</sup>       |
| Outputs the hierarchical configuration (IM configuration) of a system managed by IM Configuration Management, host information, and definition information                                                                                                                                                                                                                                                                     | <i>jcfexport</i>                          | Y       | Y    | Superuser <sup>#1</sup>       |
| Imports IM Configuration Management information                                                                                                                                                                                                                                                                                                                                                                                | <i>jcfimport</i>                          | Y       | Y    | Superuser <sup>#1</sup>       |
| Creates from the host input information file and Central Scope export file a Central Scope import file that contains monitoring tree information for a virtualization configuration. Alternatively, creates from the business group information file, monitoring group information file, and Central Scope export file a Central Scope import file to which the monitoring tree information of a business group has been added | <i>jcfmkcsdata</i>                        | Y       | Y    | Superuser <sup>#1</sup>       |
| Uses a virtualization configuration information file to update a host input information file                                                                                                                                                                                                                                                                                                                                   | <i>jcfmkhostsdata</i>                     | Y       | Y    | Superuser <sup>#1</sup>       |
| Updates the virtualization configuration of the specified host                                                                                                                                                                                                                                                                                                                                                                 | <i>jcfvirtualchstat</i>                   | Y       | Y    | Superuser <sup>#1</sup>       |
| Sets up an operating environment for the IM Configuration Management processes of JP1/IM - Manager                                                                                                                                                                                                                                                                                                                             | <i>jplcf_setup</i> (UNIX only)            | --      | Y    | Superuser                     |
| Sets up an environment for IM Configuration Management for cluster system operation                                                                                                                                                                                                                                                                                                                                            | <i>jplcf_setup_cluster</i><br>(UNIX only) | --      | Y    | Superuser                     |
| Sets up an environment for IM Configuration Management for cluster system operation                                                                                                                                                                                                                                                                                                                                            | <i>jplcfhasetup</i><br>(Windows only)     | Y       | --   | Superuser <sup>#1</sup>       |

## Commands related to IM Configuration Management (remote monitoring configuration)

| Overview of function                                                                      | Command name                         | Windows | UNIX | Required execution permission |
|-------------------------------------------------------------------------------------------|--------------------------------------|---------|------|-------------------------------|
| Defines the profile of a remote monitoring event log trap on the specified monitored host | <i>jcfaleltdef</i> (Windows only)    | Y       | --   | Superuser <sup>#1</sup>       |
| Reloads a remote monitoring event log trap action definition file                         | <i>jcfaleltreload</i> (Windows only) | Y       | --   | Superuser <sup>#1</sup>       |

| Overview of function                                                                             | Command name                       | Windows | UNIX | Required execution permission |
|--------------------------------------------------------------------------------------------------|------------------------------------|---------|------|-------------------------------|
| Starts a remote monitoring event log trap                                                        | <i>jcfaletstart (Windows only)</i> | Y       | --   | Superuser <sup>#1</sup>       |
| Displays the operating status of a remote monitoring event log trap                              | <i>jcfaletstat (Windows only)</i>  | Y       | --   | Superuser <sup>#1</sup>       |
| Stops a remote monitoring event log trap                                                         | <i>jcfaletstop (Windows only)</i>  | Y       | --   | Superuser <sup>#1</sup>       |
| Adds or deletes the profile of a remote monitoring log file trap on the specified monitored host | <i>jcfalllogdef</i>                | Y       | Y    | Superuser <sup>#1</sup>       |
| Reloads the action definition file of a remote monitoring log file trap                          | <i>jcfalllogreload</i>             | Y       | Y    | Superuser <sup>#1</sup>       |
| Starts a remote monitoring log file trap                                                         | <i>jcfalllogstart</i>              | Y       | Y    | Superuser <sup>#1</sup>       |
| Displays the operating status of a remote monitoring log file trap                               | <i>jcfalllogstat</i>               | Y       | Y    | Superuser <sup>#1</sup>       |
| Stops a remote monitoring log file trap                                                          | <i>jcfalllogstop</i>               | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands related to upgrading

| Overview of function                                                                                                                                                      | Command name                           | Windows | UNIX | Required execution permission |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|---------|------|-------------------------------|
| Converts an action definition file from version earlier than 11-50 to version 11-50 or later                                                                              | <i>jcadefconv</i>                      | Y       | Y    | Superuser <sup>#1</sup>       |
| Changes the location of the event acquisition filter from Event Console Service to Event Base Service (when the event acquisition filter is being used for compatibility) | <i>jcocahfmode (UNIX only)</i>         | Y       | Y    | Superuser <sup>#1</sup>       |
| Migrates JP1/Base command execution logs for version 7 or earlier to a command execution log file for version 8                                                           | <i>jcocmdconv<sup>#2</sup></i>         | Y       | Y    | Superuser <sup>#1</sup>       |
| Upgrades a logical host environment that was set up using a previous version of JP1/IM - Manager or JP1/IM - Manager (Central Console)                                    | <i>jp1cohaverup</i>                    | Y       | Y    | Superuser <sup>#1</sup>       |
| Upgrades a physical host environment from a previous version of JP1/IM - Manager (Central Scope)                                                                          | <i>jp1csverup.bat (Windows only)</i>   | Y       | --   | Superuser <sup>#1</sup>       |
| Upgrades a logical host environment that was set up using a previous version of JP1/IM - Manager (Central Scope)                                                          | <i>jp1cshaverup.bat (Windows only)</i> | Y       | --   | Superuser <sup>#1</sup>       |
| Upgrades a physical host environment from a previous version of JP1/IM - Manager (Central Scope)                                                                          | <i>jp1csverup (UNIX only)</i>          | --      | Y    | Superuser                     |
| Upgrades a logical host environment that was set up using a previous version of JP1/IM - Manager (Central Scope)                                                          | <i>jp1cshaverup (UNIX only)</i>        | --      | Y    | Superuser                     |

## Commands related to the Intelligent Integrated Management Base

| Overview of function                                                                                                                                                                                                               | Command name               | Windows | UNIX | Required execution permission |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|---------|------|-------------------------------|
| Collects the configuration information of the system managed by JP1/IM - Manager (Intelligent Integrated Management Base) and creates the IM management node-related files                                                         | <i>jddcreatetree</i>       | Y       | Y    | Superuser <sup>#1</sup>       |
| Collects system configuration information from the products managed by the Intelligent Integrated Management server, and creates IM management node-related files that are used as input data for the <i>jddupdatetree</i> command | <i>jddupdatetree</i>       | Y       | Y    | Superuser <sup>#1</sup>       |
| Sets a user ID and password that are used for JP1/IM - Manager (Intelligent Integrated Management Base) to be authenticated by linked products                                                                                     | <i>jddsetaccessuser</i>    | Y       | Y    | Superuser <sup>#1</sup>       |
| Sets authentication information for the proxy server when REST APIs are executed from plug-ins that are provided by JP1/IM - Manager (Intelligent Integrated Management Base)                                                      | <i>jddsetproxyuser</i>     | Y       | Y    | Superuser <sup>#1</sup>       |
| Loads user-defined suggestion definition files and applies them to JP1/IM - Manager (Intelligent Integrated Management Base).                                                                                                      | <i>jddupdatesuggestion</i> | Y       | Y    | Superuser <sup>#1</sup>       |
| Takes the Intelligent Integrated Management Base client information registered with the OpenID provider for OpenID authentication linkage, and sets it in JP1/IM - Manager (Intelligent Integrated Management Base).               | <i>jddsetopinfo</i>        | Y       | Y    | Superuser <sup>#1</sup>       |
| Takes the mapping information defined in the single sign-on mapping definition file and applies it to JP1/IM - Manager (Intelligent Integrated Management Base).                                                                   | <i>jddupdatessomap</i>     | Y       | Y    | Superuser <sup>#1</sup>       |
| Import the user-defined automatic action definition file and reflect it in the intelligent integrated management infrastructure.                                                                                                   | <i>jddupdateaction</i>     | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands related to the Intelligent Integrated Management Database

| Overview of function                                                                                                           | Command name          | Windows | UNIX | Required execution permission |
|--------------------------------------------------------------------------------------------------------------------------------|-----------------------|---------|------|-------------------------------|
| Backup the Intelligent Integrated Management Database.                                                                         | <i>jimgndbbbackup</i> | Y       | Y    | Superuser <sup>#1</sup>       |
| Recover the Intelligent Integrated Management Database stored in backup.                                                       | <i>jimgndbrestore</i> | Y       | Y    | Superuser <sup>#1</sup>       |
| Setup the Intelligent Integrated Management Database and the Trend Data Management Service.                                    | <i>jimgndbsetup</i>   | Y       | Y    | Superuser <sup>#1</sup>       |
| Un-setup the Intelligent Integrated Management Database and the Trend Data Management Service.                                 | <i>jimgndbunsetup</i> | Y       | Y    | Superuser <sup>#1</sup>       |
| Stop the Intelligent Integrated Management Database Service and the Trend Data Management Service.                             | <i>jimgndbstop</i>    | Y       | Y    | Superuser <sup>#1</sup>       |
| Checking the operating status of the Intelligent Integrated Management Database Service and the Trend Data Management Service. | <i>jimgndbstatus</i>  | Y       | Y    | Superuser <sup>#1</sup>       |

1. Commands

| Overview of function                                                                   | Command name         | Windows | UNIX | Required execution permission |
|----------------------------------------------------------------------------------------|----------------------|---------|------|-------------------------------|
| Upgrading Intelligent Integrated Management Database and trend data management service | <i>jimgndbupdate</i> | Y       | Y    | Superuser <sup>#1</sup>       |

## ■About multiple execution of the commands related to the Intelligent Integrated Management Database

The following table shows possible or not possible multiple execution of the commands related to the Intelligent Integrated Management Database.

| Execute command name | Executing command name |                |             |               |               |                |               |
|----------------------|------------------------|----------------|-------------|---------------|---------------|----------------|---------------|
|                      | jimgndbsetup           | jimgndbunsetup | jimgndbstop | jimgndbstatus | jimgndbbackup | jimgndbrestore | jimgndbupdate |
| jimgndbsetup         | Not possible           |                |             | Possible      | Not possible  |                |               |
| jimgndbunsetup       | Not possible           |                |             | Possible      | Not possible  |                |               |
| jimgndbstop          | Not possible           |                |             | Possible      | Not possible  |                |               |
| jimgndbstatus        | Possible               |                |             |               |               |                |               |
| jimgndbbackup        | Not possible           |                |             | Possible      | Not possible  |                |               |
| jimgndbrestore       | Not possible           |                |             | Possible      | Not possible  |                |               |
| jimgndbupdate        | Not possible           |                |             | Possible      | Not possible  |                |               |

## Commands related to views

| Overview of function                                                                                                         | Command name                     | Windows | UNIX | Required execution permission |
|------------------------------------------------------------------------------------------------------------------------------|----------------------------------|---------|------|-------------------------------|
| Starts IM Configuration Management - View                                                                                    | <i>jcfview (Windows only)</i>    | Y       | --   | None                          |
| Registers into or deletes from the Windows <b>Start</b> menu the menu item for starting IM Configuration Management - View   | <i>jcovfsetup (Windows only)</i> | Y       | --   | Superuser <sup>#1</sup>       |
| Opens JP1/IM - View's Login window or Monitoring Tree (Editing) window, or logs in to JP1/IM - Manager from the command line | <i>jcoview (Windows only)</i>    | Y       | --   | None                          |

## Commands related to configuration definition

| Overview of function                                                                                        | Command name                | Windows | UNIX | Required execution permission |
|-------------------------------------------------------------------------------------------------------------|-----------------------------|---------|------|-------------------------------|
| Distributes configuration definition information to the lower hosts and enables the definition information  | jbsrt_distrib <sup>#2</sup> | Y       | Y    | Superuser <sup>#1</sup>       |
| Collects configuration definition information from the lower hosts and updates the configuration definition | jbsrt_sync <sup>#2</sup>    | Y       | Y    | Superuser <sup>#1</sup>       |
| Deletes the configuration definition information for the host that executed the command                     | jbsrt_del <sup>#2</sup>     | Y       | Y    | Superuser <sup>#1</sup>       |

| Overview of function                                       | Command name                         | Windows | UNIX | Required execution permission |
|------------------------------------------------------------|--------------------------------------|---------|------|-------------------------------|
| Displays the existing configuration definition information | <code>jbsrt_get</code> <sup>#2</sup> | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands related to events

| Overview of function                          | Command name           | Windows | UNIX | Required execution permission |
|-----------------------------------------------|------------------------|---------|------|-------------------------------|
| Changes the response status for severe events | <code>jcochstat</code> | Y       | Y    | None <sup>#3</sup>            |
| Sets up a JP1/IM - Manager system environment | <code>jcoimdef</code>  | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands related to automated actions and command execution

| Overview of function                                                                                                                                            | Command name                          | Windows | UNIX | Required execution permission |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|---------|------|-------------------------------|
| Checks the definitions of automated actions and merges multiple automated action definition files                                                               | <code>jcamakea</code>                 | Y       | Y    | Superuser <sup>#1</sup>       |
| Displays the result of automated action execution                                                                                                               | <code>jcashowa</code>                 | Y       | Y    | None <sup>#3</sup>            |
| Displays to standard output the status of the Automatic Action Service that is running and the contents of the automated action definition file that is loaded. | <code>jcastatus</code>                | Y       | Y    | None <sup>#3</sup>            |
| Reloads the automated action definitions, places the automated action function on standby, or enables or disables the automated action definition.              | <code>jacachange</code>               | Y       | Y    | Superuser <sup>#1</sup>       |
| Cancels automated actions                                                                                                                                       | <code>jacacancel</code>               | Y       | Y    | Superuser <sup>#1</sup>       |
| Sets up a command execution environment                                                                                                                         | <code>jcocmddef</code> <sup>#2</sup>  | Y       | Y    | Superuser <sup>#1</sup>       |
| Outputs logs of executed commands                                                                                                                               | <code>jcocmdlog</code> <sup>#2</sup>  | Y       | Y    | None                          |
| Deletes commands that were executed from JP1/IM - View or executed by automated actions                                                                         | <code>jcocmddel</code> <sup>#2</sup>  | Y       | Y    | Superuser <sup>#1</sup>       |
| Checks the status of commands that were executed from JP1/IM - View or executed by automated actions                                                            | <code>jcocmdshow</code> <sup>#2</sup> | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands related to the email notification function

| Overview of function                                                                                                      | Command name                              | Windows | UNIX | Required execution permission |
|---------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|---------|------|-------------------------------|
| Sends email to the specified email address                                                                                | <code>jimmail</code> (Windows only)       | Y       | --   | Superuser <sup>#1</sup>       |
| Sets the password for POP before SMTP authentication or SMTP-AUTH authentication in the email environment definition file | <code>jimmailpasswd</code> (Windows only) | Y       | --   | Superuser <sup>#1</sup>       |

## Commands related to correlation event generation

| Overview of function                                                                                                                            | Command name        | Windows | UNIX | Required execution permission |
|-------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|---------|------|-------------------------------|
| Changes correlation event generation definitions                                                                                                | <i>jcoegschange</i> | Y       | Y    | Superuser <sup>#1</sup>       |
| Checks the contents of a correlation event generation definition file                                                                           | <i>jcoegscheck</i>  | Y       | Y    | Superuser <sup>#1</sup>       |
| Places the correlation event generation function in correlation running status                                                                  | <i>jcoegsstart</i>  | Y       | Y    | Superuser <sup>#1</sup>       |
| Displays the status of the correlation event generation function and the correlation event generation definitions that are being used currently | <i>jcoegsstatus</i> | Y       | Y    | None <sup>#3</sup>            |
| Places the correlation event generation function in standby status                                                                              | <i>jcoegsstop</i>   | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands used in the Central Scope environment setup

| Overview of function                                          | Command name          | Windows | UNIX | Required execution permission |
|---------------------------------------------------------------|-----------------------|---------|------|-------------------------------|
| Registers host information into the host information database | <i>jcshostsimport</i> | Y       | Y    | Superuser <sup>#1</sup>       |
| Acquires host information from the host information database  | <i>jcshostsexport</i> | Y       | Y    | Superuser <sup>#1</sup>       |
| Creates or re-creates the monitoring object database          | <i>jcsdbsetup</i>     | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands related to filters

| Overview of function                                          | Command name        | Windows | UNIX | Required execution permission |
|---------------------------------------------------------------|---------------------|---------|------|-------------------------------|
| Switches the event acquisition filter                         | <i>jcochfilter</i>  | Y       | Y    | Superuser <sup>#1</sup>       |
| Changes the operating mode of the common exclusion-conditions | <i>jcochcexmode</i> | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands related to changing the monitoring node status in Central Scope

| Overview of function                                                             | Command name     | Windows | UNIX | Required execution permission |
|----------------------------------------------------------------------------------|------------------|---------|------|-------------------------------|
| Changes the status of monitoring nodes (monitoring objects or monitoring groups) | <i>jcschstat</i> | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands for migrating monitoring object database information in Central Scope

| Overview of function                                                                                           | Command name       | Windows | UNIX | Required execution permission |
|----------------------------------------------------------------------------------------------------------------|--------------------|---------|------|-------------------------------|
| Acquires monitoring object database storage information from JP1/IM - Manager and outputs it locally to a file | <i>jcsdbexport</i> | Y       | Y    | Superuser <sup>#1</sup>       |

| Overview of function                                                                                                                   | Command name       | Windows | UNIX | Required execution permission |
|----------------------------------------------------------------------------------------------------------------------------------------|--------------------|---------|------|-------------------------------|
| Applies the information output to a file by the <code>jcsdbexport</code> command to the monitoring object database of JP1/IM - Manager | <i>jcsdbimport</i> | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands used for troubleshooting

| Overview of function                                                                                   | Command name                             | Windows | UNIX | Required execution permission |
|--------------------------------------------------------------------------------------------------------|------------------------------------------|---------|------|-------------------------------|
| Creates a Java thread dump of IM Configuration Management - View                                       | <i>jcfthreaddmp</i><br>(Windows only)    | Y       | --   | None                          |
| Collects data in the event of a failure in JP1/IM - Manager or JP1/IM - View                           | <i>jim_log.bat</i><br>(Windows only)     | Y       | --   | None <sup>#3</sup>            |
| Collects data in the event of a failure in JP1/IM - Manager                                            | <i>jim_log.sh</i> (UNIX only)            | --      | Y    | Superuser                     |
| Collects data in the event of a failure in JP1/IM - View                                               | <i>jcoview_log.bat</i><br>(Windows only) | Y       | --   | None <sup>#3</sup>            |
| Outputs a thread dump in the event of a failure in JP1/IM - View                                       | <i>jcothreaddmp</i><br>(Windows only)    | Y       | --   | None                          |
| Outputs a thread dump and a core dump (UNIX only) in the event of a failure in JP1/IM - Manager        | <i>jcogencore</i>                        | Y       | Y    | Superuser <sup>#1</sup>       |
| Tests the notification command that is defined in the health check definition file in JP1/IM - Manager | <i>jcohctest</i>                         | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands for checking the contents of the JP1/IM - Manager definition file

| Overview of function                                     | Command name            | Windows | UNIX | Required execution permission |
|----------------------------------------------------------|-------------------------|---------|------|-------------------------------|
| Checks the definition file for extended event attributes | <i>jcoattrfcheck</i>    | Y       | Y    | None <sup>#3</sup>            |
| Checks the definition file for opening monitor windows   | <i>jcomonitorfcheck</i> | Y       | Y    | None <sup>#3</sup>            |

## Commands for checking the contents of the JP1/IM - View definition file

| Overview of function                                    | Command name                              | Windows | UNIX | Required execution permission |
|---------------------------------------------------------|-------------------------------------------|---------|------|-------------------------------|
| Checks the definition file for executing applications   | <i>jcoappexecfcheck</i><br>(Windows only) | Y       | N    | None                          |
| Checks the definition file for the Tool Launcher window | <i>jcofuncfcheck</i><br>(Windows only)    | Y       | N    | None                          |

## Command that counts the number of nodes managed by JP1/IM - Manager

| Overview of function                                   | Command name        | Windows | UNIX | Required execution permission |
|--------------------------------------------------------|---------------------|---------|------|-------------------------------|
| Counts the number of nodes managed by JP1/IM - Manager | <i>jimnodecount</i> | Y       | Y    | Superuser <sup>#1</sup>       |

## Commands related to the JP1/IM - Agent

| Overview of function                                                                | Command name                                 | Windows | UNIX | Required execution permission |
|-------------------------------------------------------------------------------------|----------------------------------------------|---------|------|-------------------------------|
| Perform configuration file format checks and test alert rules for Prometheus server | <i>promtool</i>                              | Y       | Y    | None                          |

## Commands for SAP system monitoring

| Overview of function                                   | Command name    | Windows | UNIX | Required execution permission |
|--------------------------------------------------------|-----------------|---------|------|-------------------------------|
| Extracts the system log information of the SAP system. | <i>jr3slget</i> | Y       | Y    | None                          |
| Extracts the CCMS alert information of the SAP system. | <i>jr3alget</i> | Y       | Y    | None                          |

## Notes common to all commands

---

### Notes about 32-bit cmd.exe(for Windows)

These commands are not compatible for 32-bit cmd.exe. Use 64-bit cmd.exe instead.

### Notes about parallel execution

The following commands or functions are not allowed to run in parallel.

- jpc\_service
- jpc\_service\_autostart
- jpc\_service\_start
- jpc\_service\_stop
- definition file manipulation function
- jima\_log
- jima\_log\_aix
- jimalhsetup
- jimalhupdate

### Notes about the environment without systemd (for Linux)

The following commands or functions are not allowed to run in the environment without systemd(e.g. container environments).

- jpc\_service
- jpc\_service\_autostart
- jpc\_service\_start
- jpc\_service\_stop
- definition file manipulation function(uploading JP1/IM - Agent definition files)
- jimalhsetup
- jimalhupdate

## Function

This command cancels automated actions. It is used to delete from JPI/IM - Manager the following actions that are no longer needed for system operation:

- Actions that remain in the queuing state without being executed because many automated actions have been performed during system operation
- Actions that remain in the running state because a command that needs time to be processed or processing of which does not end has been executed

The command executed for an action can be deleted by the `jcocmd del` command, but the status of the action does not change to canceled. Use the `jcocmd del` command to delete an action that cannot be canceled by using the `jcacancel` command.

For details about the `jcocmd del` command, see the chapters related to commands in the *JPI/Base User's Guide*.

The action status after cancellation depends on the action status before cancellation. The following table lists and describes the action statuses that can be canceled and the action statuses after cancellation.

Table 1–1: Statuses of actions that can be canceled and the action statuses after cancellation

| Status of action that can be canceled | Action status after cancellation <sup>#1</sup> |
|---------------------------------------|------------------------------------------------|
| Wait or Wait (Miss)                   | Cancel                                         |
| Send (Miss) <sup>#2</sup>             |                                                |
| Queue or Queue (Miss)                 |                                                |
| Running or Running (Miss)             | Kill                                           |

#1: If an error occurs in JPI/Base command control during cancellation processing, the action status is set to `Error (Miss)`.

#2: An action whose status is `Send` cannot be canceled. If an attempt is made to cancel such an action, the action status is set to `Send (Miss)`.

## Format

```
jcacancel [-h logical-host-name]
           { [-i action-serial-number,...] | [-a] | [-s action-executing-host
-name] }
           [-f]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path\bin\*

In UNIX:

/opt/jplcons/bin/

## Arguments

**-h** *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. The command cancels automated actions that correspond to the specified logical host. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

**-i** *action-serial-number*

Specifies an automated action that is to be canceled.

You can determine the action serial numbers by using the `jcashowa` command or by displaying the List of Action Results window and the Action Log Details window in JP1/IM - View. You can specify a maximum of 20 action serial numbers. If you specify multiple action serial numbers, separate them with the comma (,). No other options can be specified between action serial numbers.

If you specify multiple action serial numbers and an error occurs on one action serial number during execution, processing continues. As many error messages are displayed as there are errors.

If you specify multiple action serial numbers in the **-i** option (in order to cancel multiple actions) and then multiple errors occur, the return value of the `jcacancel` command is for the last error that occurred.

**-a**

Specifies that all automated actions that are to be executed from the JP1/IM where `jcacancel` is executed and that exist on all monitored hosts are to be canceled.

If you specify the **-a** option to cancel multiple actions and multiple errors occur, the return value of the `jcacancel` command is for the last error that occurred.

**-s** *action-executing-host-name*

Specifies a host name when the automated actions that are to be canceled are the automatic actions executed from the JP1/IM where `jcacancel` is executed and that exist on the specified action executing host.

You can specify only a host that has been set as a managed host in the system configuration definition. Neither an IP address nor a host group can be specified.

If you specify the **-s** option to cancel multiple actions and multiple errors occur, the return value of the `jcacancel` command is for the last error that occurred.

**-f**

Specifies that the automated actions are to be canceled without displaying a configuration message during cancellation processing.

## Notes

- Processing if the target host is restarted during cancellation processing

If the target host where automated actions are to be executed is restarted during automated action cancellation processing, the cancellation status of actions cannot be acquired. Therefore, the action status remains as `Wait (Canceling)`, `Send (Canceling)`, `Queue (Canceling)`, or `Running (Canceling)`, making it impossible to determine whether cancellation processing was successful. Use the `jcocmdshow` command to check the results. If there are any remaining actions, delete them with the `jcocmddel` command.

## Return values

|     |                                                                                     |
|-----|-------------------------------------------------------------------------------------|
| 0   | Normal termination                                                                  |
| 1   | Invalid argument error                                                              |
| 2   | Invalid common definition error                                                     |
| 3   | Invalid action status error                                                         |
| 4   | Cancellation processing error                                                       |
| 5   | Input/output error                                                                  |
| 6   | There was no response from the automated action function (Automatic Action Service) |
| 7   | Execution permission error (Windows only)                                           |
| 255 | System error                                                                        |

### Example 1

Cancel multiple automated actions (action serial numbers 23, 35, and 42):

```
jcacancel -i 23,35,42
```

### Example 2

Cancel all automated actions that are executed from the `hostA` logical host and that exist on all hosts that are monitored by the `hostA` logical host:

```
jcacancel -h hostA -a
```

### Example 3

Cancel the automated actions that are executed from the JP1/IM that executes `jcacancel` and that exist on the `host01` host:

```
jcacancel -s host01
```

### Example 4

Cancel the automated actions that are executed from the `hostB` logical host and that exist on `host02`, which is monitored by the `hostB` logical host:

```
jcacancel -h hostB -s host02
```

### Example 5

Cancel the automated actions that are monitored by the `hostC` logical host and that have specified action serial numbers (23, 35, and 42):

```
jcacancel -h hostC -i 23,35,42
```

## Function

This command reloads the automated action definition file, places the automated action function on standby, or, enables or disables the automated action definition.

If both options are omitted, the command reloads the automated action definition file. After you have changed the contents of the automated action definition file, you use this command to activate the modified action definitions by reloading the file.

This command skips invalid action definitions in the automated action definition file, and continues processing.

If the automated action definition file contains an invalid action definition, the command displays the KAVB5104-W message. If you want to reload the automated action definition file you edited, before executing the `jcachange` command, execute the `jcamakea` command to make sure that there are no errors in the automated action definition file.

If the KAVB5104-W message is displayed, review the contents of the automated action definition file.

If the loaded automated action definition file contains no valid action definitions, the command displays the KAVB4053-I message and places the automated action function on standby.

When this command is executed with no option specified, the suppression time and the status of satisfied AND-joined conditions are initialized for all action execution conditions. When this command is executed with the `-e`, `-on`, `-off`, or `-st` option specified, the suppression time and the status of satisfied AND-joined conditions are not initialized unless the definition of the action execution condition is changed.

A reloaded automated action definition parameter that exceeds the maximum size is ignored by the command. For details about the size of an automated action definition parameter, see [Automated action definition file \(actdef.conf\)](#) in *Chapter 2. Definition Files*.

## Format

```
jcachange [-n] [-h logical-host-name]
           [-e [action-ID[,action-ID...] | ALL]]
           [-on action-ID[,action-ID...]]
           [-off action-ID[,action-ID...]]
           [-st]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jp1cons/bin/

## Arguments

`-n`

Specifies that the automated action function is to be placed on standby. No actions are executed even if an event that matches an action definition is received.

To restart the automated action function, either execute the `jcachange` command with no options specified or restart JP1/IM - Manager.

`-h logical-host-name`

When you are operating in a cluster system, this option specifies the logical host name. The command reloads or places on standby the action definitions for the specified logical host. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

`-e [action-ID[,action-ID...] | ALL]`

Specifies the action ID of an action definition to enable. Other action definitions whose IDs are not specified in this option are disabled. To specify multiple IDs, separate them with a comma (,). To enable all actions, specify `ALL`.

Executing the command with this option changes every `valid` parameter in the action definition file. When the action ID is specified, the corresponding `valid` parameter is changed to `true`. When the action ID is not specified, it is changed to `false`. When `ALL` is specified, all `valid` parameters are changed to `true`.

This option is available only when `DESC_VERSION` of the action definition file is 4.

When the action definition of a specified action ID is not found in the action definition file, the `KAVB4028-E` message is sent to the standard error output and integrated trace log, and the command ends with a return code of 10. When no action execution condition is defined in the action definition file and `ALL` is specified for this option, the `KAVB4029-E` message is sent to the standard error output and integrated trace log, and the command ends with a return code of 10. When no action execution condition is defined in the action definition file and no action ID is specified for this option, the `KAVB4029-E` message is sent to the standard error output and integrated trace log, and the command ends with a return code of 11.

`-on action-ID[,action-ID...]`

Specifies the action ID of an action definition to enable. To specify multiple IDs, separate them with a comma (,). The status of other action definitions whose IDs are not specified remains the same. This option cannot be combined with the `-e` option.

Executing the command with this option changes the `valid` parameters of the specified action IDs in the action definition file to `true`.

This option is available only when `DESC_VERSION` of the action definition file is 4.

When the action definition of a specified action ID is not found in the action definition file, the `KAVB4028-E` message is sent to the standard error output and integrated trace log, and the command ends with a return code of 10.

`-off action-ID[,action-ID...]`

Specifies the action ID of an action definition to disable. To specify multiple IDs, separate them with a comma (,). The status of other action definitions whose IDs are not specified remains the same. This option cannot be combined with the `-e` option.

Executing the command with this option changes the `valid` parameters of the specified action IDs in the action definition file to `false`.

This option is available only when `DESC_VERSION` of the action definition file is 4.

When the action definition of a specified action ID is not found in the action definition file, the `KAVB4028-E` message is sent to the standard error output and integrated trace log, and the command ends with a return code of 11.

-st

Specifies that executing the command will not initialize the suppression status and the status of satisfied conditions of the AND-joined conditions when the following is true for the action execution condition:

- There is no difference between the definition of the action execution condition that works in the Event Base Service and the definition that is specified in the action definition file.

This option is available only when `DESC_VERSION` of the action definition file is 4. Only the `-h` option can be combined with this option.

## Notes

Executing the `jcachange` command concurrently many times might cause timeouts or a degraded performance of managers.

## Return values

|             |                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------|
| 0           | Normal termination                                                                                              |
| 4           | There was no response from the automated action function                                                        |
| 5           | Command failed to reload the automated action definition file or place the automated action function on standby |
| 10          | There is no action definition that is to be enabled                                                             |
| 11          | There is no action definition that is to be disabled                                                            |
| 12          | Failed to update due to failure to acquire exclusive rights for the automated action definition file            |
| 13          | Failed to read due to failure to acquire exclusive rights for the automated action definition file              |
| 111         | Failed to connect to the Event Base Service or the Event Console Service (in UNIX)                              |
| 154         | File input/output error (in UNIX)                                                                               |
| 243         | A specified argument value was invalid (in UNIX)                                                                |
| -13         | A specified argument value was invalid (in Windows)                                                             |
| -102        | File input/output error (in Windows)                                                                            |
| -401        | Failed to connect to the Event Base Service or the Event Console Service (in Windows)                           |
| Other value | System error                                                                                                    |

## Function

This command converts an action definition file from version earlier than 11-50 (DESC\_VERSION value is less than 4) to version 11-50 or later (DESC\_VERSION value is 4).

If the action definition file for version 8 or earlier uses any of the characters listed below in its messages or in basic event information, detailed event information, or extended event information, the file is converted and defined.

Table 1–2: Character conversion

| Character before conversion | Characters after conversion |
|-----------------------------|-----------------------------|
| V                           | /                           |
| Space                       | %20                         |
| %                           | %25                         |

Before it executes this conversion, this command automatically checks the format of the action definition file. If it detects any errors, the action definition file is not converted and the command outputs error messages to standard error.

You can specify any output destination for the converted action definition file.

An action definition file is converted from version 8 or earlier to version 11-50 or later as shown below.

Table 1–3: Conversion of action definition files

| Format of version 8 or earlier  | Format of version 11-50 or later                             | Remarks |
|---------------------------------|--------------------------------------------------------------|---------|
| No DESC_VERSION                 | DESC_VERSION=4                                               | --      |
| DESC_VERSION=1                  | DESC_VERSION=4                                               | --      |
| DESC_VERSION=2                  | DESC_VERSION=4                                               | --      |
| DESC_VERSION=3                  | DESC_VERSION=4                                               | --      |

| --                                         | aidΔ <i>action-ID</i>                                                                                                                         | An action ID is assigned to an action execution condition from the top of the action definition in the order at which the action execution conditions are listed. The ID increments from 0 to 2,147,483,647. Note that no action ID is assigned to the action execution condition whose parameter group is set to &. |
| --                                         | validΔtrue                                                                                                                                    | The valid parameter is set to true (enabled). However, this parameter is not changed for the action execution condition whose parameter group is set to &.                                                                                                                                                           |

Legend:

- ▲ : Indicates a tab
- Δ: Indicates a space
- : None

## Format

```
jcdefconv -i action-definition-file-name-before-conversion
           -o action-definition-file-name-after-conversion
           [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path\bin\*

In UNIX:

*/opt/jp1cons/bin/*

## Arguments

**-i** *action-definition-file-name-before-conversion*

Specifies the relative or absolute path name of the action definition file that is to be converted. If the path name of the action definition file contains a space, enclose the entire path name in double quotation marks ("). The file name can consist of a maximum of 255 bytes.

**-o** *action-definition-file-name-after-conversion*

Specifies the relative or absolute path name of the action definition file that is obtained after conversion. If the path name of the action definition file contains a space, enclose the entire path name in double quotation marks ("). The file name can consist of a maximum of 255 bytes.

Note that the following characters and character strings cannot be specified in a file name in Windows:

- Characters: : ? " < > |
- A character string that completely matches any of the following strings (not case sensitive): CON, PRN, AUX, NUL, COM1, COM2, COM3, COM4, COM5, COM6, COM7, COM8, COM9, LPT1, LPT2, LPT3, LPT4, LPT5, LPT6, LPT7, LPT8, LPT9

The user can select any name for *action-definition-file-name-after-conversion*, except that it cannot be the file name specified in the **-i** option. Furthermore, if a file that has the same name as the name of the file specified in the **-o** option, the KAVB5504-E message is displayed and the program terminates.

**-h** *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. The command checks the contents of the definition file to be converted by using regular expressions used by the specified logical host.

If this option is omitted, the command assumes the logical host name specified in the JP1\_HOSTNAME environment variable. If the JP1\_HOSTNAME environment variable is not specified, the command assumes the physical host name.

## Notes

- If you use the **-i** or **-o** option to specify the automated action definition used in JP1/IM - Manager, do so after stopping JP1/IM - Manager.
- When a file is converted to the format of version 11-50 or later, some items become undefined. If such an undefined item is present, the KAVB5505-W message is displayed. Follow the directions in the message to correct the action definition file, and then use the `jcamakea` command to check that the definition file has been corrected successfully.

## Return values

|   |                          |
|---|--------------------------|
| 0 | Normal termination       |
| 1 | Abnormal termination     |
| 2 | Termination with warning |

## Example

The following is an example of converting an action definition file that was created in the format of version 8 or earlier to the format of version 11-50 or later:

```
jcadefconv -i actdef.conf -o actdef_new.conf
```

The example assumes the following contents for the action definition file created in the format of version 8 or earlier:

```
DESC_VERSION=2
:state_watch=true
#comment
+0 $0000000A /message/,/basic-event-information/,/detailed-event-information
/,/-----E/ ATTR1=/attribute-value-1/ : u=user-name e=environment-variable
-file-name d=execution-host-name dt=20 rt=30 action
```

When the `jcadefconv` command is executed, the file is converted as follows:

```
DESC_VERSION=4
cmn
  sta true
end-cmn
act action-1
  aid action-ID
  valid true
  prm 0
  cmt comment
  eid A
  cnd
    B.MESSAGE REGEX message
    B.BASIC REGEX basic-event-information
    B.DETAIL REGEX detailed-event-information
    E.SEVERITY IN Emergency
    E.ATTR1 REGEX attribute-value-1
  end-cnd

  usr user-name
  hst execution-host-name
  cmd action
  var environment-variable-file-name
  det 20
  ret 30
end-act
```

## Function

This command checks the definitions of automated actions. If the definitions span multiple automated action definition files, the command merges the files into one file. When multiple automated action definition files are to be merged, the command uses the version of the action definition file and the automated action status monitoring parameter that apply to the first file that is loaded.

The checking and merging results are output to standard output. The command checks the output results and creates the automated action definition file.

If the command detects errors during checking, it outputs error messages to standard error.

An automated action definition parameter in a specified automated action definition file that exceeds the maximum size is not output to standard output. For details about the size of an automated action definition parameter, see [Automated action definition file \(actdef.conf\)](#) in *Chapter 2. Definition Files*.

If a file contains no definition parameters or contains only comments, an error results.

## Format

```
jcamakea [-h logical-host-name] automated-action-definition-file-name-1 [...  
utomated-action-definition-file-name-100]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jplcons/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host that contains the regular expressions to be used to check the contents of the definition files that are to be converted. The command checks the contents of the definition files to be converted using the regular expressions used by the specified logical host. The command also checks whether any automated action definition file exceeds the maximum file size according to the file size settings in the specified logical host. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

*automated-action-definition-file-name-1* [ . . . *automated-action-definition-file-name-100*]

Specifies the relative or absolute path names of the files containing automated action definitions. You can specify a maximum of 100 files. Separate multiple file names with the space character. If the path name of an automated action definition file contains a space, enclose the entire path name in double quotation marks (").

A file name can consist of a maximum of 255 bytes.

## Return values

|      |                                      |
|------|--------------------------------------|
| 0    | Normal termination                   |
| 3    | Invalid argument                     |
| 7    | Format error or no permission        |
| 152  | System error (in UNIX)               |
| 153  | Insufficient memory (in UNIX)        |
| 154  | File open error (in UNIX)            |
| 156  | Logical error (in UNIX)              |
| 255  | File open error (in UNIX)            |
| -1   | File open error (in Windows)         |
| -100 | Logical error (in Windows)           |
| -102 | File input/output error (in Windows) |
| -103 | Insufficient memory (in Windows)     |
| -104 | System error (in Windows)            |

When the command reads an action definition file in the format of version 08-50 or earlier, it sets one of the following return values:

0: Normal termination

Other than 0: Abnormal termination

If multiple errors occur, the return value is for the last error that occurred.

## Example

Merge automated action definition files `/usr/console/action1` and `/usr/console/action2` to create the automated action definition file `/usr/console/actionx1`:

```
jcamakea /usr/console/action1 /usr/console/action2 > /usr/console/actionx1
```

## Function

This command displays the results of executing automated actions stored in an action information file. Automated action execution results can be displayed for an event that was registered at a specified date and time, or for all events that were registered during a specified period of time, or for all actions.

## Format

```
jcashowa [-d { [MM/dd/hh:mm] [, [MM/dd/hh:mm]] } ]
          [-h logical-host-name]
          [action-information-file-name]
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In UNIX: None

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jplcons/bin/

## Arguments

**-d** { [MM/dd/hh:mm] [, [MM/dd/hh:mm]] }

Specifies the time that the events subject to the actions stored in the action information file were registered. Use a comma (,) to separate the beginning date and time from the ending date and time. The command displays information about the actions for events that were registered during the specified period of time. When this option is omitted, the command displays information about all the actions stored in the action information file.

About the date/time specification (MM/dd/hh:mm):

You can use the formats shown in the table below for the date/time specification. Use the format appropriate to your operation.

**Table 1–4: Date/time specification formats**

| Date/time specification pattern | Description                                                                                        |
|---------------------------------|----------------------------------------------------------------------------------------------------|
| MM/dd/hh:mm                     | Specify month in MM, date in dd, hour in hh, and minute in mm.                                     |
| MM/dd/hh                        | Specify month in MM, date in dd, and hour in hh.<br>For the omitted mm, the command assumes 00.    |
| MM/dd                           | Specify month in MM and date in dd.<br>For the omitted hh and mm, the command assumes 00 for both. |
| dd                              | Specify date in dd.                                                                                |

| Date/time specification pattern | Description                                                                                                                                                                                                                                                   |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | For the omitted <i>MM</i> , the command assumes the month the <code>jcashowa</code> command was executed. For <i>hh</i> and <i>mm</i> , the command assumes 00 for both.                                                                                      |
| <i>dd/hh:mm</i>                 | Specify date in <i>dd</i> , hour in <i>hh</i> , and minute in <i>mm</i> .<br>For the omitted <i>MM</i> , the command assumes the month the <code>jcashowa</code> command was executed.                                                                        |
| <i>hh:mm</i>                    | Specify hour in <i>hh</i> and minute in <i>mm</i> .<br>For the omitted <i>MM</i> , the command assumes the month the <code>jcashowa</code> command was executed. For <i>dd</i> , the command assumes the date the <code>jcashowa</code> command was executed. |

About the date/time range specification (`[MM/dd/hh:mm] [, [MM/dd/hh:mm]]`):

You can use the formats shown in the table below for the date/time range specification. Use the format appropriate to your operation.

Table 1–5: Date/time range specification formats

| Range specification pattern        | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-d datetime</code>           | By specifying <i>datetime</i> , you can display the result of an action that was executed for an event registered at a specific date and time.<br>For example, to display the result of an action that was executed for an event registered at 22:00 on October 24, specify as follows:<br><code>jcashowa -d 10/24/22:00</code>                                                                                 |
| <code>-d datetime, datetime</code> | By specifying <i>datetime, datetime</i> , you can display the results of all actions that were executed for the events registered during a specified period (range) of time.<br>For example, to display the results of the actions that were executed for all events registered from 22:00 on October 24 through 10:00 on November 24, specify as follows:<br><code>jcashowa -d 10/24/22:00, 11/24/10:00</code> |
| <code>-d datetime,</code>          | By specifying <i>datetime,</i> , you can display the results of all actions that were executed for the events registered on and subsequent to the specified date and time.<br>For example, to display the results of the actions that were executed for the events registered at 22:00 on October 24 and thereafter, specify as follows:<br><code>jcashowa -d 10/24/22:00,</code>                               |
| <code>-d , datetime</code>         | By specifying <i>, datetime</i> , you can display the results of all actions that were executed for the events registered at and before the specified date and time.<br>For example, to display the results of the actions that were executed for the events registered up to (and including) 10:00 on November 24, specify as follows:<br><code>jcashowa -d , 11/24/10:00</code>                               |

About the default year:

If the specified beginning month value is greater than the value for the month during which the `jcashowa` command is executed, the command assumes the specified date and time belong to the previous year and treats the specification as being from the beginning date and time in the previous year to the ending date and time in the current year.

- When the specified beginning month value is greater than the value for the month during which the `jcashowa` command is executed:  
12 (December)  $\geq$  value specified as the beginning month  $>$  value for the month during which the `jcashowa` command is executed  
The command assumes that the year for the specified beginning date and time is the year preceding the year during which the `jcashowa` command is executed.
- When the specified beginning month value is less than the value for the month during which the `jcashowa` command is executed:

Value for the month during which the `jcashowa` command is executed  $\geq$  value specified as the beginning month  $\geq 01$  (January)

The command assumes that the year for the specified beginning date and time is the same as the year during which the `jcashowa` command is executed.

Example 1 (if the `jcashowa` command is executed on 2003/10/31):

```
# jcashowa -d 11/01/0:00,10/01/23:59
```

The command assumes the specified time range is from 2002/11/01 0:00 to 2003/10/01 23:59 and performs processing normally.

Example 2 (if the `jcashowa` command is executed on 2003/11/01):

```
# jcashowa -d 11/01/0:00,10/01/23:59
```

The command assumes the specified time range is from 2003/11/01 0:00 to 2003/10/01 23:59 and displays the message `KAVB4009-W` because the specified date and time are not in chronological order.

The specification of the `-d` option determines the chronicity of the specified dates/times. If the specified beginning and ending dates/times are not in chronological order, an error results.

### *About the seconds specification*

For the seconds specification, 00 is assumed as the beginning time and 59 is assumed as the ending time.

Example 1 (if the `jcashowa` command is executed as follows):

```
# jcashowa -d 10/24/22:00
```

The results of actions executed from October 24, 22:00:00 to October 24, 22:00:59 are displayed.

Example 2 (if the `jcashowa` command is executed as follows):

```
# jcashowa -d 10/24/22:00,11/24/10:00
```

The results of actions executed from October 24, 22:00:00 to November 24, 10:00:59 are displayed.

### *-h logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. The command displays action execution results for the specified logical host. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

### *action-information-file-name*

Specifies the full path of the file to be used for the action information file.

If you specify an action information file at the physical host, do not specify the `-h` option or the `JP1_HOSTNAME` environment variable.

If you specify an action information file at the logical host, specify the logical host name in the `-h` option or the `JP1_HOSTNAME` environment variable.

The action information file name can consists of a maximum of 255 bytes.

The specified action information file will be used to store information about the executed actions.

This option must be the final option specified in the command. It must be specified after you have specified all other options that need to be specified.

## Return values

|   |                                                |
|---|------------------------------------------------|
| 0 | Normal termination                             |
| 3 | Argument error                                 |
| 6 | System error                                   |
| 7 | No permission to execute the command (Windows) |

## Output format

When you execute the `jcashowa` command, automated action information is output in the following format:

Event information<sup>#1</sup> *event-ID*Δ*serial-number*Δ*registered-time*Δ*event-arrival-time*

Action information<sup>#2</sup> *action-serial-number*Δ*action-type*Δ*status*Δ*delay-status*Δ*PID*Δ*execution-host-name*

Action information *action-inserted-time*Δ*action-starting-time*Δ*action-ending-time*Δ*return-code*

Command *command*

Message *message*

#1

If an AND condition is specified in the automated action settings, the command outputs only information about the last event received among all the events set in the execution condition.

#2

If no delay monitoring setting is specified for the action or the action is not delayed, the command outputs the following information:

Action information *action-serial-number*Δ*action-type*Δ*status*Δ*PID*Δ*execution-host-name*

The following table lists and described each item that is output.

Table 1–6: Automated action information output items

| Item                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

```

#### Example 3:

The command status is running, the cancellation status is canceling, and no message has been output:

```

Event information: 00002000:00000000 20 12/03 12:03:26
                  12/03 12:03:26
Action information: 10 Command running(canceling) 15236 raysol
Action information: 12/03 12:09:15 12/03 12:09:16
                  **/** **:**:** **
Command:          /usr/local/action

```

#### Example 4:

There are results for multiple actions:

```

Event information: 00002000:00000000 20 12/03 12:03:26
                  12/03 12:03:26
Action information: 380 Command ended 233 raysol
Action information: 12/03 12:09:13 12/03 12:09:14
                  12/03 12:09:14 20
Command:          /usr/local/action
Event information: 00002000:00000000 20 12/03 12:03:26
                  12/03 12:03:26
Action information: 381 Command ended 279 raysol
Action information: 12/05 10:39:20 12/05 10:39:21
                  12/05 10:39:23 128
Command:          /usr/local/action2
Message:          No permission
Execute as a superuser
Processing is canceled

```

#### Example 5:

There are multiple actions for a single event because a parameter group was specified:

```

Event information: 00002000:00000000 20 12/03 12:03:26
                  12/03 12:03:26
Action information: 987 Command running 2904 raysol
Action information: 12/05 10:39:20 12/05 10:39:21
                  12/03 12:09:13 0
Command:          /usr/local/first
Event information: 00002000:00000000 20 12/03 12:03:26
                  12/03 12:03:26
Action information: 988 Command ended 2906 raysol
Action information: 12/05 10:39:20 12/05 10:39:21
                  12/06 21:02:54 0
Command:          /usr/local/second

```

#### Example 6:

Action information was entered in the action re-execution file due to node switching:

```

Event information: 00002000:00000000 20 12/03 12:03:26
                  12/03 12:03:26
Action information: 45687 Command ended-R OUTPUT

```

```
Action information: **/** **:**:** *** **/** **:**:** ***  
/****:**:** ***
```

#### Example 7:

The action being executed is delayed:

```
Event information: 00002000:00000000 20 12/03 12:03:26  
12/03 12:03:26  
Action information: 987 Command running delay 2904 raysol  
Action information: 12/05 10:39:20 12/05 10:39:21  
**/** **:**:** ***  
Command: /usr/local/executing
```

# jcastatus

## Function

Using standard output, this command displays the status (stopped, running, standby) of the automated action function that is running, and the contents of the automated action definition file that is loaded by the active automated action function.

Note that you can execute multiple instances of this command concurrently.

## Format

```
jcastatus [-h logical-host-name]  
          [-d]
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In UNIX: None

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jplcons/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. The command displays the status of the automated action function (Event Base Service) that corresponds to the specified logical host. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-d (at Event Base Service)

Specifies that the contents of the automated action definition file that is loaded by the automated action function is displayed to standard output. The command displays the information in the same format as in the automated action definition file.

Even when all automated action definitions are disabled, the contents of the automated action definition file that is loaded by the active automated action function are displayed to standard output.

## Return values

|   |                                                                                                                                                                 |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | Normal termination                                                                                                                                              |
| 4 | No response from the automated action function (Event Base Service)                                                                                             |
| 5 | Command cannot display the contents of the automated action definition file because the automated action function (Event Base Service) is stopped or on standby |
| 6 | System error (at the command)                                                                                                                                   |

|      |                                                     |
|------|-----------------------------------------------------|
| 152  | System error (at Event Base Service) (in UNIX)      |
| 154  | Input/output error (in UNIX)                        |
| 243  | A specified argument value was invalid (in UNIX)    |
| -13  | A specified argument value was invalid (in Windows) |
| -102 | Input/output error (in Windows)                     |
| -104 | System error (at Event Base Service) (in Windows)   |

## Output format

When you execute the `jcastatus` command, the status of the automated action function is output in the following format:

Status : *status*

The following table describes the character strings that can be displayed as *status*.

Table 1–7: Statuses of the automated action function

| Character string displayed in status | Status  | Description                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STOP                                 | Stopped | The automated action function (Event Base Service) is stopped.                                                                                                                                                                                                                                                              |
| RUNNING                              | Running | The automated action function (Event Base Service) is running and available for use.                                                                                                                                                                                                                                        |
| STANDBY                              | Standby | The Event Base Service is running, but the automated action function is in the standby mode.<br>In this status, events are still received, but no action is taken on the received events.<br>If the status changes from standby to running, action is not taken on the events that were received while in the standby mode. |

## Example output

The automated action function is in the standby mode:

```
Status : STANDBY
```

## jcfaletdef (Windows only)

---

### Function

Defines the profile of a remote monitoring event log trap on the specified monitored host. The definition is overwritten whether the profile on the specified monitored host is running or has stopped.

To perform a batch reload, use the `jcfaletdef` command to overwrite multiple running remote monitoring event log traps, and then use the `jcfaletreload` command to batch-reload the profiles.

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running.
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.

### Format

```
jcfaletdef -f remote-monitoring-event-log-trap-action-definition-file-name
           -o monitored-host-name
           [-filter filter]
           [-h logical-host-name]
```

### Execution permission

Administrator permissions

### Storage directory

*Manager-path*\bin\imcf\

### Arguments

`-f remote-monitoring-event-log-trap-action-definition-file-name`

Specifies the name of an action definition file.

Specify the action definition file name as the full path or a relative path from the current directory with a maximum of 256 bytes. When specifying a relative path, do so in such a way that the full-path name with the directory name will not be more than 256 bytes.

The action definition file can be placed in any directory, and any file name can be specified.

`-o monitored-host-name`

Specifies the name of the monitored host for a remote monitoring event log trap whose profile you want to define. Note that the OS on the monitored host must be Windows.

`-filter filter`

Specifies the log type to filter on when the system has been set up to collect only event logs from a remotely monitored host.

When this option is specified, only event logs that match the specified log type are transferred to the manager. Specify this option to control the amount of log file data that is transferred from a remotely monitored host to the manager.

Use a character string in the following table to specify the log type. Note that the character strings are not case sensitive.

| Specifiable log type | Log type of event logs to be filtered |
|----------------------|---------------------------------------|
| Error                | Error, Critical                       |
| Warning              | Warning                               |
| Information          | Information, Verbose                  |
| Audit_success        | Security Audit Success                |
| Audit_failure        | Security Audit Failure                |

To specify multiple log types, use a comma ( , ) as a separator. Do not insert a space before or after the comma.

#### **-h *logical-host-name***

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name specified for the JP1\_HOSTNAME environment variable is set. If no logical host name is set for JP1\_HOSTNAME, the physical host name is set.

## **Return values**

|             |                                                         |
|-------------|---------------------------------------------------------|
| 0           | Addition successful                                     |
| 4           | Invalid argument                                        |
| 6           | Unable to connect to the server                         |
| 7           | Invalid host information                                |
| 10          | Error in obtaining exclusive edit rights                |
| 14          | Invalid DB                                              |
| 17          | Invalid permission                                      |
| 18          | Input/output error                                      |
| 21          | Upper limit for number of concurrent executions reached |
| 255         | Internal error                                          |
| Other value | Other error                                             |

## **Example 1**

Add a profile on host1:

```
jcfaletdef -f actionDefinition.conf -o host1
```

## **Example 2**

Filter to obtain only the error, warning, and failed-audit event logs when a profile has been added on host1:

```
jcfaletdef -f actionDefinition.conf -o host1 -filter Error,Warning,Audit_failure
```

## jcfaeltreload (Windows only)

---

### Function

Reloads remote monitoring event log traps. If trap processing is being performed when the command is executed, the traps are reloaded after the trap processing has finished. When a start option has been changed by using the `jcfaeltdef` command or the Display/Edit Profiles window, the change is not applied by the reload operation. Restart the system to apply the change.

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running.
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.
- DCOM is set.
- A remote monitoring event log trap is running.

### Format

```
jcfaeltreload {-o monitored-host-name | ALL}  
               [-h logical-host-name]
```

### Execution permission

Administrator permissions

### Storage directory

*Manager-path*\bin\imcf\

### Arguments

-o *monitored-host-name*

Specifies the name of the monitored host for the remote monitoring event log traps you want to reload. The OS on the monitored host must be Windows.

ALL

All remote monitoring event log traps are reloaded.

-h *logical-host-name*

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name specified for the `JP1_HOSTNAME` environment variable is set. If no logical host name is set for `JP1_HOSTNAME`, the physical host name is set.

### Return values

|   |                          |
|---|--------------------------|
| 0 | Reloading successful     |
| 2 | Partial or total failure |
| 4 | Invalid argument         |

|              |                                                                    |
|--------------|--------------------------------------------------------------------|
| 6            | Unable to connect to the server                                    |
| 7            | Invalid host information                                           |
| 10           | Error in obtaining exclusive edit rights                           |
| 11           | Invalid action definition file                                     |
| 12           | Invalid authentication definition file                             |
| 13           | Communication error                                                |
| 14           | Invalid DB                                                         |
| 15           | The specified remote monitoring event log trap has already stopped |
| 17           | Invalid permission                                                 |
| 18           | Input/output error                                                 |
| 21           | Upper limit for number of concurrent executions reached            |
| 255          | Internal error                                                     |
| Other values | Other error                                                        |

## Example

Reload the remote monitoring event log trap on `host1`:

```
jcfaleltreload -o host1
```

# jcfaleltstart (Windows only)

---

## Function

Starts a remote monitoring event log trap.

Executing this command collects the event log files on the monitored host specified in the option, converts a line in a log file that satisfies the conditions specified in the action definition file of a remote monitoring event log trap to a JP1 event, and registers the event on an event server.

In order to specify the `-f` option, the action definition file of a remote monitoring event log trap must be created before the command is executed. Also, if the command is executed with the `-f` option specified and the profile has stopped, the existing action definition file of the remote monitoring event log trap is overwritten and the process for the trap profile is started. If the profile is running, the existing action definition file of the remote monitoring event log trap is overwritten and saved on the server, and an error message is displayed. At this point, the profile is running with the operation definition that existed before the action definition was overwritten.

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.
- DCOM is set.

## Format

```
jcfaleltstart
-o monitored-host-name
[-h logical-host-name]
[-f remote-monitoring-event-log-trap-action-definition-file-name
[-filter filter]]
```

## Execution permission

Administrator permissions

## Storage directory

*Manager-path*\bin\imcf\

## Arguments

`-o monitored-host-name`

Specifies the name of the monitored host for the remote monitoring event log traps you want to start. The OS on the monitored host must be Windows.

`-h logical-host-name`

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name specified for the `JP1_HOSTNAME` environment variable is set. If no logical host name is set for `JP1_HOSTNAME`, the physical host name is set.

**-f *remote-monitoring-event-log-trap-action-definition-file-name***

Specifies the name of an action definition file. If the -f option is specified, the existing action definition file of a remote monitoring event log trap is overwritten and started. If the -f option is not specified, the existing remote monitoring event log trap is started.

Specify the action definition file name as a full path or a relative path from the current directory with a maximum of 256 bytes. When specifying a relative path, do so in such a way that the full-path name with the directory name will be no more than 256 bytes.

The action definition file can be placed in any directory, and any file name can be specified.

**-filter *filter***

Specifies a filter, when filters have already been set, according to log type to filter event logs acquired on a remotely monitored host. This option can be specified only when the -f option is specified.

When this option is specified, only event logs that match the specified log type are transferred to the manager. Specify this option to control the amount of log file data that is transferred from a remotely monitored host to the manager.

Use a character string in the following table to specify the log type. Note that the character strings are not case sensitive.

| Specifiable log type | Log type of event logs to be filtered |
|----------------------|---------------------------------------|
| Error                | Error, Critical                       |
| Warning              | Warning                               |
| Information          | Information, Verbose                  |
| Audit_success        | Security Audit Success                |
| Audit_failure        | Security Audit Failure                |

To specify multiple log types, use a colon ( , ) as a separator. Do not insert a space before or after the colon.

## Return values

|     |                                                         |
|-----|---------------------------------------------------------|
| 0   | Trap started successfully                               |
| 4   | Invalid argument                                        |
| 6   | Unable to connect to the server                         |
| 7   | Invalid host information                                |
| 8   | Already running                                         |
| 9   | Profile threshold value exceeded                        |
| 10  | Error in obtaining exclusive edit rights                |

## Example 1

Start a remote monitoring event log trap on host1:

```
jcfaeltstart -o host1 -f actionDefinition.conf
```

## Example 2

Filter to obtain only the error, warning, and failed-audit event logs when a remote monitoring event log trap on host1 is started:

```
jcfaeltstart -o host1 -f actionDefinition.conf -filter Error,Warning,Audit_failure
```

# jcfaleltstat (Windows only)

---

## Function

Displays the operating status of a remote monitoring event log trap.

When this command is executed, the operating status of a remote monitoring event log trap that monitors the monitored host specified as the argument is returned.

If ALL is specified in the `-o` option and there is no host in the remote monitoring configuration, or if the OS is not Windows, a message indicating this status appears.

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.

## Format

```
jcfaleltstat {-o monitored-host-name | ALL}  
             [-h logical-host-name]
```

## Execution permission

Administrator permissions

## Storage directory

*Manager-path*\bin\imcf\

## Display format

When the `jcfaleltstat` command is executed, the output result is displayed in the format shown below.

#

In this example, the line number is added at the beginning of each line for descriptive purposes:

1 *message-ID*Δ*message*

2 *message-ID*Δ*message*

3 *host-name*Δ*status*

4 *host-name*Δ*status*

5 *host-name*Δ*status*

6 :

- Line 1

A message indicating that command execution has started is displayed.

- Line 2  
A message indicating the following display scope is displayed:
  - All
  - Specified hosts
  - Specified event log traps on the specified host
- Lines 3 to 6  
The statuses related the event log traps on the remotely monitored hosts (Windows) for the specified scope are displayed. The following statuses are displayed:
  - **START:** The event log trap is running.
  - **STOP:** The event log trap has stopped.
  - **EDIT:** The action definition file for the event log trap is being edited, but the changes have not been applied.
  - **FAIL:** The event log trap status could not be obtained:
    - The host is invalid (host information was not collected, or collection failed))
    - An error occurred during WMI communication.
    - An authentication error occurred
    - An input/output error occurred.
    - An error occurred during an attempt to obtain exclusive rights.
    - An internal error occurred.

## Arguments

–o *monitored-host-name*

Specifies the name of the monitored host for a remote monitoring event log trap whose operating status you want to check. The OS on the monitored host must be Windows.

ALL

Checks the operating status of all remote monitoring event log traps.

–h *logical-host-name*

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name specified for the JP1\_HOSTNAME environment variable is set. If no logical host name is set for JP1\_HOSTNAME, the physical host name is set.

## Return values

|    |                                                                                       |
|----|---------------------------------------------------------------------------------------|
| 0  | All remote monitoring event log traps are running                                     |
| 1  | Some remote monitoring event log traps are running (when the ALL option is specified) |
| 2  | Partial or total failure                                                              |
| 4  | Invalid argument                                                                      |
| 6  | Unable to connect to the server                                                       |
| 7  | Invalid host information                                                              |
| 14 | Invalid DB                                                                            |
| 17 | Invalid permission                                                                    |
| 18 | Input/output error                                                                    |

|              |                                                         |
|--------------|---------------------------------------------------------|
| 19           | All remote monitoring event log traps have stopped.     |
| 21           | Upper limit for number of concurrent executions reached |
| 255          | Internal error                                          |
| Other values | Other error                                             |

## Example

Display the operating status of a remote monitoring event log trap on host1:

```
jcfaleltstat -o host1
```

# jcfaletstop (Windows only)

## Function

Stops remote monitoring event log traps.

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.
- DCOM is set.
- A remote monitoring log file trap is running.

## Format

```
jcfaletstop {-o monitored-host-name | ALL}  
            [-h logical-host-name]
```

## Execution permission

Administrator permissions

## Storage directory

*Manager-path*\bin\imcf\

## Arguments

-o *monitored-host-name*

Specifies the name of the monitored host for the remote monitoring event log traps you want to stop. The OS on the monitored host must be Windows.

ALL

Stops all remote monitoring event log traps.

-h *logical-host-name*

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name specified for the JP1\_HOSTNAME environment variable is set. If no logical host name is set for JP1\_HOSTNAME, the physical host name is set.

## Return values

|   |                                 |
|---|---------------------------------|
| 0 | Stopped successfully            |
| 2 | Partial or total failure        |
| 4 | Invalid argument                |
| 6 | Unable to connect to the server |
| 7 | Invalid host information        |

|              |                                                                    |
|--------------|--------------------------------------------------------------------|
| 10           | Error in obtaining exclusive edit rights                           |
| 12           | Invalid authentication definition file                             |
| 13           | Communication error                                                |
| 14           | Invalid DB                                                         |
| 15           | The specified remote monitoring event log trap has already stopped |
| 17           | Invalid permission                                                 |
| 18           | Input/output error                                                 |
| 21           | Upper limit for number of concurrent executions reached            |
| 255          | Internal error                                                     |
| Other values | Other error                                                        |

## Example

Stop all remote monitoring event log traps:

```
jcfaleltstop ALL
```

# jcfsallogdef

---

## Function

Adds or deletes the profile of a remote monitoring log file trap on the specified monitored host. Specifying the `-f` option adds the profile, and specifying the `-d` option deletes the profile.

If an added profile has the same monitoring name as an existing profile on the specified monitored host, the action definition file is overwritten whether the profile is running or has stopped.

This command can be executed only when the profile specified for deletion has stopped.

To perform a batch reload, use the `jcfsallogdef` command to overwrite multiple running remote monitoring log file traps, and then use the `jcfsallogreload` command to batch-reload the profiles.

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.

## Format

```
jcfsallogdef
    -a monitoring-name
    -o monitored-host-name
    [-h logical-host-name]
    {-f remote-monitoring-log-file-trap-action-definition-file-name
     -c character-encoding
     [-filter filter]
     [-m maximum-length-of-data-treated-as-event (bytes)]
     [-p log-data-output-source-program-name]
     [-r]
     [-t file-monitoring-interval (seconds)]
     log-file-name1 [...log-file-name32] |
    -d}
    [-q]
```

## Execution permission

In Windows: Administrator permissions

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

### -a *monitoring-name*

Specifies the monitoring name used to identify a remote monitoring log file trap.

Specify a character string with a maximum of 30 bytes for the monitoring name. Alphanumeric characters, hyphens (-), and underlines can be used. The first character must be an alphanumeric character. The monitoring name is not case sensitive.

A paired monitoring name and monitored host must be unique, and cannot be the same as another pair specified by `jcfallogstart`. Note, however, that the same monitoring name as the one specified by `jevlogstart` of JP1/Base can be used.

### -o *monitored-host-name*

Specifies the name of the monitored host for a remote monitoring log file trap to which you want to add or from which you want to delete a profile.

### -h *logical-host-name*

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name specified for the `JP1_HOSTNAME` environment variable is set. If no logical host name is set for `JP1_HOSTNAME`, the physical host name is set.

### -f *remote-monitoring-log-file-trap-action-definition-file-name*

Specifies the name of an action definition file.

Specify the action definition file name as a full path or a relative path from the current directory with a maximum of 256 bytes. When specifying a relative path, do so in such a way that the full-path name with the directory name will be no more than 256 bytes.

The action definition file can be placed in any directory, and any file name can be specified.

### -c *character-encoding*

Specifies the character encoding of a log file. This option can be specified only when the `-f` option is specified.

You can specify the following character encodings.

Table 1–8: Character codes

| OS    | Japanese                                                                                                                                                                                                                                                                                                                                                                                   | English                                             | Chinese                                                                                                                                                                                                                                                                                                 |

#1

Valid only when the monitored OS is SUSE Linux.

#2

If the product runs on an English OS, the character encoding is C even if you specify SJIS for the character encoding.

**-filter** *filter*

Specifies a filter, when filters have already been set, that uses regular expressions to filter log files obtained on a remotely monitored host.

When this option is specified, only log data that matches the specified regular expressions is transferred to the manager. Specify this option to control the amount of log file data that is transferred from a remotely monitored host to the manager.

This option can be specified only when the `-f` option is specified.

This option is valid only when the OS on the remotely monitored host is UNIX. As a prerequisite condition, the `grep` command must be able to be executed over a SSH connection. When the OS on the remotely monitored host is Windows and this option is specified, it is ignored.

The regular expression formats that can be specified are the same as the formats of the extended regular expressions that can be specified in the `-E` option for the `grep` command on the remotely monitored host. No environment variables can be used.

Specify a character string with a maximum of 128 bytes for regular expressions. Characters that can be specified in the string are ' ', '<', '>', alphanumeric characters (excluding control characters), spaces, and symbols. If the character string contains a space, the entire string must be enclosed in double quotation marks (" ).

Path examples for the `grep` command are given below. For details, see the documentation about the `grep` command in the applicable OS.

- For Linux: `/bin/grep`
- For Solaris: `/usr/xpg4/bin/grep`
- For an OS other than Linux and Solaris: `/usr/bin/grep`

`-m` *maximum-length-of-data-treated-as-event* (bytes)

Specifies the number of bytes to be read from the beginning of a line in a log file. From 1 to 1,024 bytes can be specified. If this option is omitted, 512 is set.

The last character in the line is converted to the `\0` symbol and indicates the end of the line. If a line in a log file exceeds the number of bytes specified for this option, the last byte is converted to `\0`.

The value specified for this option indicates the valid length of a line in the entered log file. Therefore, ensure that the regular expressions in the `MARKSTR` parameter in the action definition file of a remote monitoring log file trap and the regular expressions in the `ACTDEF` parameter are within the length specified here. In short, if there are any regular expressions corresponding to a column that exceed the valid length, they are not checked.

`-p` *log-data-output-source-program-name*

Specifies the name of the program to which log data is output. The specified name is displayed in the Event Console window of JP1/IM - View.

The following names are displayed.

In Windows:

`/HITACHI/JP1/NT_LOGTRAP/log-data-output-source-program-name`

In UNIX:

`/HITACHI/JP1/UX_LOGTRAP/log-data-output-source-program-name`

If this option is omitted, `/HITACHI/JP1/NT_LOGTRAP` is displayed for Windows and `/HITACHI/JP1/UX_LOGTRAP` is displayed for UNIX.

`-r`

If this option is omitted and any of the following cases apply, the system tries to collect data at the interval specified in the `-t` option until the log data can be collected.

- The remotely monitored host cannot be accessed when the remote monitoring log file trap starts.
- The remotely monitored host cannot be accessed while the remote monitoring log file trap is running
- The log file that is to be monitored cannot be accessed when the remote monitoring log file trap starts
- The log file that is to be monitored cannot be accessed while the remote monitoring log file trap is running

Specify the `-r` option for the following cases:

- The remotely monitored host can be accessed after the remote monitoring log file trap starts.
- The log file that is to be monitored is created after a remote monitoring log file trap starts.
- You want to continue monitoring the remotely monitored host even if it cannot be accessed.

If this option is omitted, one or the other of the following occurs:

- If the log file that is to be monitored cannot be obtained when the remote monitoring log file trap starts, the startup process stops and processing terminates.
- If the log file that is to be monitored cannot be collected while it is running, retry is attempted for the number of times specified in the action definition file for the log file trap at the interval specified in the file.

`-t file-monitoring-interval` (seconds)

Specifies the file monitoring interval. A value from 60 to 86,400 (seconds) can be specified. If this option is omitted, 300 is set.

When a log file in WRAP2 format is monitored

If wrap-around is performed frequently or a long monitoring interval is specified, the remote monitoring log file trap is overwritten before it reads data, causing some data to be lost. To prevent unread data, use the following formula for the monitoring interval:

$$\text{log-file-size (bytes)} \times \text{number-of-log-files} > \text{output-size-per-second (bytes)} \times \text{monitoring-interval (seconds)}$$

`log-file-name1 [ . . . log-file-name32 ]`

Specifies the names of the log files to be monitored. Specify a character string with a maximum of 256 bytes for a log file name. If the monitored host OS is Windows, use the network path name without the host name for specification. If the OS is UNIX, use the full-path name. Note that wildcard characters cannot be specified for a log file to be monitored.

For a monitored host running UNIX, only log files with file paths consisting of alphanumeric characters, hyphens (-), underscores (\_), periods (.), and slashes (/) can be monitored. File paths that include any other characters might not be monitored correctly.

A maximum of 32 files, and the following file formats, can be specified:

- Sequential file (SEQ)
- Sequential file (SEQ2)
- Wrap around file (WRAP2)

`-d`

Deletes the profile of a remote monitoring log file trap.

Because specifying this option deletes the remote monitoring log file trap from the profile tree, a message is displayed to confirm that there is no problem.

`-q`

If this option is specified, no confirmation message is displayed when the `-d` option is specified. If `-d` option is not specified, this option is ignored.

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.

If you execute with standby host in UNIX / Linux, an unwanted directory named `/shared-directory-name` is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- */shared-directory-name/jplimm*
- */shared-directory-name/jplimm/log*
- */shared-directory-name/jplimm/log/imcf*

Delete these unwanted directory and files, they will never to be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|              |                                                                                                 |

## Example 1

Add a profile on host1:

```
jcfallogdef -a name1 -o host1 -f actionDefinition.conf -c SJIS -filter ".*-E" /log/sample.log
```

## Example 2

Delete a profile on host1:

```
jcfallogdef -a name1 -o host1 -d -q
```

## Function

Reloads the action definition file of a remote monitoring log file trap.

The only definition information you can reload is that specified by the `MARKSTR` and `ACTDEF` parameter values of the action definition file. If a value other than the `MARKST` and `ACTDEF` parameter values is changed by using the `jcfallogdef` command or the Display/Edit Profiles window, the change is not applied by reloading the definition file. Restart the system to apply the change. Also, if the reload command is executed at the same time trap processing is executed, the information to be reloaded is applied to the trap processing.

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.
- For SSH communication, SSH authentication can be performed by using the applicable remotely monitored host and public key encryption.
- For NetBIOS (NetBIOS over TCP/IP) communication, the log file to be monitored is shared.
- A remote monitoring log file trap is being started.

## Format

```
jcfallogreload {-o monitored-host-name [-a monitoring-name] | ALL}  
               [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

-o *monitored-host-name*

Specifies the name of the monitored host for a remote monitoring log file trap you want to reload.

-a *monitoring-name*

Specifies the monitoring name of a remote monitoring log file trap you want to reload.

Specify a character string with a maximum of 30 bytes for the monitoring name. Alphanumeric characters, hyphens (-), and underlines can be used. The first character must be an alphanumeric character. The monitoring name is not case sensitive.

ALL

Reloads the action definition file of each remote monitoring log file trap.

-h *logical-host-name*

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name specified for the JP1\_HOSTNAME environment variable is set. If no logical host name is set for JP1\_HOSTNAME, the physical host name is set.

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.  
If you execute with standby host in UNIX / Linux, an unwanted directory named */shared-directory-name* is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- */shared-directory-name/jplimm*
- */shared-directory-name/jplimm/log*
- */shared-directory-name/jplimm/log/imcf*

Delete these unwanted directory and files, they will never to be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|     |                                                                |
|-----|----------------------------------------------------------------|
| 0   | Reloading successful                                           |
| 2   | Partial or total failure                                       |
| 4   | Invalid argument                                               |
| 6   | Unable to connect to the server                                |
| 7   | Invalid host information                                       |

| 12  | Invalid authentication definition file                         |
| 13  | Communication error                                            |
| 14  | Invalid DB                                                     |
| 15  | The specified remote monitoring log file trap is already ended |
| 17  | Invalid permission                                             |
| 18  | Input/output error                                             |
| 21  | Upper limit for number of concurrent executions reached        |
| 255 | Internal error                                                 |

|              |             |
|--------------|-------------|
| Other values | Other error |
|--------------|-------------|

## Example

Reload the remote monitoring log file trap name1 on host1:

```
jcfaologreload -o host1 -a name1
```

# jcfaologstart

---

## Function

Starts a remote monitoring log file trap.

Executing this command collects log files on a monitored host, and sets a line in a log file that matches the conditions in the action definition file of the remote monitoring log file trap as a JP1 event. The event is then registered on an event server.

Specifying the `-f` option adds a new profile for a remote monitoring log file trap, and then starts a process. If a profile with the same monitoring name already exists on the specified monitored host when the profile has stopped, the trap's action definition file is overwritten, and a remote monitoring log file trap process is started. If the profile is running, the action definition file is overwritten and saved on the server, and an error message is displayed before the process stops. At this point, the profile is running with the operation definition that existed before the action definition was overwritten. If the `-f` option is not specified, the profile process for an existing remote monitoring log file trap is started.

Log files in different data formats cannot be processed together. For such cases, start a separate remote monitoring log file trap for each format.

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.
- For SSH communication, SSH authentication can be performed by using the applicable remotely monitored host and public key encryption.
- For NetBIOS (NetBIOS over TCP/IP) communication, the log file to be monitored is shared.

## Format

```
jcfaologstart
  -a monitoring-name
  -o monitored-host-name
  [-h logical-host-name]
  [-f remote-monitoring-log-file-trap-action-definition-file-name]
  -c character-encoding
  [-filter filter]
  [-m maximum-length-of-data-treated-as-event (bytes)]
  [-p log-data-output-source-program-name]
  [-r]
  [-t file-monitoring-interval (seconds)]
  log-file-name1 [ ... log-file-name32 ]
```

## Execution permission

In Windows: Administrator permissions

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

### -a *monitoring-name*

Specifies the monitoring name used to identify the remote monitoring log file trap.

Specify a character string with a maximum of 30 bytes for the monitoring name. Alphanumeric characters, hyphens (-), and underlines can be used. The first character must be an alphanumeric character. The monitoring name is not case sensitive.

A paired monitoring name and a monitored host must be unique, and cannot be the same as another pair specified by jcfallogstart. Note, however, that the same monitoring name as the one specified by jevlogstart of JP1/Base can be used.

### -o *monitored-host-name*

Specifies the name of the monitored host for a remote monitoring log file trap you want to start.

### -h *logical-host-name*

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name specified for the JP1\_HOSTNAME environment variable is set. If no logical host name is set for JP1\_HOSTNAME, the physical host name is set.

### -f *remote-monitoring-log-file-trap-action-definition-file-name*

Specifies the name of the action definition file as a full path or a relative path from the current directory with a maximum of 256 bytes. When specifying a relative path, do so in such a way that the full-path name with the directory name will be no more than 256 bytes.

The action definition file can be placed in any directory, and any file name can be specified.

Specifying this option creates a new remote monitoring log file trap and starts it. If this option is omitted, an existing remote monitoring log file trap is started.

### -c *character-encoding*

Specifies the character encoding of a log file. This option can be specified only when the -f option is specified.

The following character encodings can be specified.

Table 1–9: Character codes

| OS  | Japanese                                                                                                                                                                                                                                                                             | English                                             | Chinese                                                                                                                                                                                                                                                                                                       |

#1

Valid only when the monitored OS is SUSE Linux.

If the product runs on an English OS, the character encoding is C even if you specify SJIS for the character encoding.

### **-filter** *filter*

Specifies a filter, when filters have already been set, that uses regular expressions to filter log files obtained on a remotely monitored host.

When this option is specified, only log data that matches the specified regular expressions is transferred to the manager. Specify this option to control the amount of log file data that is transferred from a remotely monitored host to the manager.

This option can be specified only when the **-f** option is specified.

This option is valid only when the OS on the remotely monitored host is UNIX. As a prerequisite condition, the **grep** command must be able to be executed over an SSH connection. When the OS on the remotely monitored host is Windows and this option is specified, it is ignored.

The regular expression formats that can be specified are the same as the formats of the extended regular expressions that can be specified in the **-E** option for the **grep** command on the remotely monitored host. No environment variables can be used.

Specify a character string with a maximum of 128 bytes for regular expressions. Characters that can be specified in the string are ' ', '<', '>', alphanumeric characters (excluding control characters), spaces, and symbols. If the character string contains a space, the entire string must be enclosed in double-quotation marks ("").

Path examples for the **grep** command are given below. For details, see the documentation about the **grep** command in the applicable OS.

- For Linux: /bin/grep
- For Solaris: /usr/xpg4/bin/grep
- For an OS other than Linux and Solaris: /usr/bin/grep

### **-m** *maximum-length-of-data-treated-as-event* (bytes)

Specifies the number of bytes to be read from the beginning of a line in a log file. From 1 to 1,024 bytes can be specified. If this option is omitted, 512 is set.

The last character in the line is converted to the \0 symbol and indicates the end of the line. If a line in a log file exceeds the number of bytes specified for this option, the last byte is converted to \0.

The value specified for this option indicates the valid length of a line in the entered log file. Therefore, ensure that the regular expressions in the **MARKSTR** parameter in the action definition file of a remote monitoring log file trap and the regular expressions in the **ACTDEF** parameter are within the length specified here. In short, if there are any regular expressions corresponding to a column that exceed the valid length, they are not checked.

### **-p** *log-data-output-source-program-name*

Specifies the name of the program to which log data is output. The specified name is displayed in the Event Console window of JP1/IM - View.

The following names are displayed.

In Windows:

/HITACHI/JP1/NT\_LOGTRAP/*log-data-output-source-program-name*

In UNIX:

/HITACHI/JP1/UX\_LOGTRAP/*log-data-output-source-program-name*

If this option is omitted, /HITACHI/JP1/NT\_LOGTRAP is displayed for Windows and /HITACHI/JP1/UX\_LOGTRAP is displayed for UNIX.

### **-r**

If this option is omitted and any of the following cases apply, the system tries to collect data at the interval specified in the **-t** option until the log data can be collected.

- The remotely monitored host cannot be accessed when the remote monitoring log file trap is started
- The remotely monitored host cannot be accessed while the remote monitoring log file trap is running
- The log file that is to be monitored cannot be accessed when the remote monitoring log file trap is started
- The log file that is to be monitored cannot be accessed while the remote monitoring log file trap is running

Specify the `-r` option for the following cases:

- The remotely monitored host can be accessed after the remote monitoring log file trap starts.
- The log file that is to be monitored is created after a remote monitoring log file trap starts.
- You want to continue monitoring a remotely monitored host even if you cannot access it.

If this option is omitted, one or the other of the following occurs:

- If the log file that is to be monitored cannot be obtained when the remote monitoring log file trap starts, the startup process stops and processing terminates.
- If the log file that is to be monitored cannot be collected while it is running, retry is attempted for the number of times specified in the action definition file for the log file trap at the interval specified in the file.

`-t file-monitoring-interval` (seconds)

Specifies the file monitoring interval. A value from 60 to 86,400 (seconds) can be specified. If you omit this option, 300 is set.

When a log file in WRAP2 format is monitored

If wrap-around is performed frequently or a long monitoring interval is specified, the remote monitoring log file trap is overwritten before it reads data, causing some data to be lost. To prevent unread data, use the following formula for the monitoring interval:

$$\text{log-file-size (bytes)} \times \text{number-of-log-files} > \text{output-size-per-second (bytes)} \times \text{monitoring-interval (seconds)}$$

`log-file-name1 [ . . . log-file-name32 ]`

Specifies the names of the log files to be monitored. Specify a character string with a maximum of 256 bytes for the log file name. If the monitored host OS is Windows, use the network path name without the host name for specification. If the OS is UNIX, use the full-path name. Note that wildcard characters cannot be specified for the log file to be monitored.

For a monitored host running UNIX, only log files with file paths consisting of alphanumeric characters, hyphens (-), underscores (\_), periods (.), and slashes (/) can be monitored. File paths that include any other characters might not be monitored correctly.

A maximum of 32 files, and the following file formats, can be specified:

- Sequential file (SEQ)
- Sequential file (SEQ2)
- Wrap around file (WRAP2)

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.

If you execute with standby host in UNIX / Linux, an unwanted directory named `/shared-directory-name` is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- `/shared-directory-name/jplimm`

- */shared-directory-name/jplimm/log*
- */shared-directory-name/jplimm/log/imcf*

Delete these unwanted directory and files, they will never be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|              |                                                         |
|--------------|---------------------------------------------------------|
| 0            | Trap started successfully                               |
| 4            | Invalid argument                                        |
| 6            | Unable to connect to the server                         |
| 7            | Invalid host information                                |
| 8            | The specified monitoring name is already running        |
| 9            | Profile threshold value exceeded                        |
| 10           | Error in obtaining exclusive edit rights                |
| 11           | Invalid action definition file                          |
| 12           | Invalid authentication definition file                  |
| 13           | Communication error                                     |
| 14           | Invalid DB                                              |
| 17           | Invalid permissions                                     |
| 18           | Input/output error                                      |
| 21           | Upper limit for number of concurrent executions reached |
| 255          | Internal error                                          |
| Other values | Other error                                             |

## Example 1

Start the remote monitoring log file trap `monitoringName` on `host1`:

```
jcfallogstart -a monitoringName -o host1
```

## Example 2

Create a new action definition file for a remote monitoring log file trap and start it:

```
jcfallogstart -a monitoringName -o host2 -f actionDefinition.conf -c SJIS -f  
ilter ".*-E" /log/sample.log
```

# jcfalllogstat

---

## Function

Displays the operating status of a remote monitoring log file trap.

Executing this command returns the operating status of a remote monitoring log file trap that has the monitoring name specified as the argument or that monitors the monitored host specified as the argument.

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.

## Format

```
jcfalllogstat {-o monitored-host-name [-a monitoring-name] | ALL}  
               [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Display format

Executing the `jcfalllogstat` command displays the output result in the format described below. Note that when ALL is specified and there are no hosts in the remote monitoring configuration, or when the specified host does not exist in the remote monitoring configuration, a message to that effect is displayed.

Note:

In this example, a line number is added at the beginning of each line for descriptive purposes:

- 1 *message-ID*Δ*message*
- 2 *message-ID*Δ*message*
- 3 [*host-name*]
- 4 *monitoring-name*Δ*status*
- 5 *monitoring-name*Δ*status*

6 *monitoring-name*Δ*status*

7 [*host-name*]

8 [*host-name*]

9 Δ*status*

10 :

- Line 1  
A message indicating that command execution has started is displayed.
- Line 2  
A message indicating the following display scope is displayed:
  - All
  - Specified host
  - Specified log file traps on the specified host
- Lines 3 to 6  
The statuses of the log file traps on the remotely monitored host for the specified scope are displayed. The following statuses are displayed:
  - START: The log file trap is running.
  - STOP: The log file trap has stopped.
  - EDIT: The action definition file for the log file trap is being edited, but the changes have not been applied.
  - FAIL: The log file trap status could not be obtained for one of the following reasons:
    - The host is invalid (host information was not collected, or collection failed).
    - An error occurred in SSH or WMI/NetBIOS (NetBIOS over TCP/IP) communication.
    - An authentication error occurred.
    - An input/output error occurred.
    - An error occurred during an attempt to obtain exclusive rights.
    - An internal error occurred.
- Line 7  
If no log file traps are defined, only the host name is displayed.
- Lines 8 and 9  
If an error has occurred on a host but the status could not be obtained, only FAIL is displayed.
- Line 10  
The statuses of log file traps on all remotely monitored hosts for the specified scope are displayed.

## Arguments

–o *monitored-host-name*

Specifies the name of the monitored host for a remote monitoring log file trap whose operating status you want to check.

–a *monitoring-name*

Specifies the monitoring name of a remote monitoring log file trap whose operating status you want to check.

Specify a character string with a maximum of 30 bytes for the monitoring name. Alphanumeric characters, hyphens (-), and underlines can be used. The first character must be an alphanumeric character. The monitoring name is not case sensitive.

ALL

Specifies the monitoring names of all log file traps.

-h *logical-host-name*

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name is set. If this option is omitted, the logical host name specified for the JP1\_HOSTNAME environment variable is set. If no logical host name is set for JP1\_HOSTNAME, the physical host name is set.

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.  
If you execute with standby host in UNIX / Linux, an unwanted directory named */shared-directory-name* is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- */shared-directory-name/jplimm*
- */shared-directory-name/jplimm/log*
- */shared-directory-name/jplimm/log/imcf*

Delete these unwanted directory and files, they will never to be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|              |                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------|
| 0            | All remote monitoring log file traps are running                                                                         |
| 1            | Some remote monitoring log file traps are running (When the ALL option is specified, or only the -o option is specified) |
| 2            | Partial or total failure                                                                                                 |
| 4            | Invalid argument                                                                                                         |
| 6            | Unable to connect to the server                                                                                          |
| 7            | Invalid host information                                                                                                 |
| 14           | Invalid DB                                                                                                               |
| 17           | Invalid permission                                                                                                       |
| 18           | Input/output error                                                                                                       |
| 19           | All remote monitoring log file traps have stopped                                                                        |
| 21           | Upper limit for number of concurrent executions reached                                                                  |
| 255          | Internal error                                                                                                           |
| Other values | Other error                                                                                                              |

## Example

Display the operating status of the remote monitoring log file trap `name1` on `host1`:

```
jcfaologstat -o host1 -a name1
```

# jcfaologstop

---

## Function

Stops remote monitoring log file traps.

The following options are provided:

- Period of time that traps stop (individually or batched)
- Whether stopped remote monitoring log file traps should be deleted

Note that a maximum of five commands can be executed concurrently.

The following conditions must be satisfied to execute this command:

- The IM Configuration Management service is running
- There is a remotely monitored host in the remote monitoring configuration.
- A remotely monitored host has already collected host information.
- For SSH communication, SSH authentication can be performed by using the applicable remotely monitored host and public key encryption.
- For NetBIOS (NetBIOS over TCP/IP) communication, the log file to be monitored is shared.
- A remote monitoring log file trap is running.

## Format

```
jcfaologstop {-o monitored-host-name [-a monitoring-name] | ALL}  
              [-d]  
              [-h logical-host-name]  
              [-q]
```

## Execution permission

In Windows: Administrator permissions

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

-o *monitored-host-name*

Specifies the name of the monitored host for a remote monitoring log file trap you want to stop.

-a *monitoring-name*

Specifies the monitoring name of a remote monitoring log file trap you want to stop.

Specify a character string with a maximum of 30 bytes for the monitoring name. Alphanumeric characters, hyphens (-), and underlines can be used. The first character must be an alphanumeric character. The monitoring name is not case sensitive.

ALL

Stops all remote monitoring log file traps.

-d

Specifying this option deletes the entry for the remote monitoring log file trap you want to stop from the profile tree. If this option is used together with the -a, -o, or ALL option, multiple remote monitoring log file traps are removed from the profile tree. In this case, a message is output to confirm that there is no problem. If this option is used together with any other option, it is ignored.

-h *logical-host-name*

Specifies the name of the logical host on which you want to execute the command. If this option is omitted, the logical host name specified for the JP1\_HOSTNAME environment variable is set. If no logical host name is set for JP1\_HOSTNAME, the physical host name is set.

-q

If this option is specified, a confirmation message is not displayed when the -d option is specified. If -d option has not been specified, this option is ignored.

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.  
If you execute with standby host in UNIX / Linux, an unwanted directory named */shared-directory-name* is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.
  - */shared-directory-name/jplimm*
  - */shared-directory-name/jplimm/log*
  - */shared-directory-name/jplimm/log/imcf*

Delete these unwanted directory and files, they will never to be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|    |                                          |
|----|------------------------------------------|
| 0  | Stopping or deletion successful          |
| 2  | Partial or total failure                 |
| 4  | Invalid argument                         |
| 6  | Unable to connect to the server          |
| 7  | Invalid host information                 |
| 10 | Error in obtaining exclusive edit rights |
| 12 | Invalid authentication definition file   |
| 13 | Communication error                      |
| 14 | Invalid DB                               |

|              |                                                                                                         |
|--------------|---------------------------------------------------------------------------------------------------------|
| 15           | The specified remote monitoring log file trap has already stopped (when the -d option is not specified) |
| 17           | Invalid permission                                                                                      |
| 18           | Input/output error                                                                                      |
| 21           | Upper limit for number of concurrent executions reached                                                 |
| 255          | Internal error                                                                                          |
| Other values | Other error                                                                                             |

## Example 1

Stop the remote monitoring log file trap `name1` on `host1`:

```
jcfsallogstop -o host1 -a name1
```

## Example 2

Stop and then delete all remote monitoring log file traps:

```
jcfsallogstop ALL -d
```

## Function

This command acquires virtualization configuration information from VMware ESX and outputs it to a virtualization configuration information file.

In order to collect the virtual host name of a guest OS from VMware ESX, VMware Tools must be running on the guest OS. The virtual host name cannot be collected if VMware Tools is not installed or if it is installed but not running.

The virtual host name also cannot be collected if the guest OS itself is not running.

This command uses the interface of VMware Infrastructure SDK for communication.

## Format

```
jcfcolvmesx
    [-m communication-type]
    -u user-ID
    [-p password]
    -c host-name [host-name]
    -o output-file-name
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

-m *communication-type*

Specifies the method used to communicate with VMware ESX.

If `https` is specified, HTTPS is used for communication with VMware ESX. If `http` is specified, HTTP is used for communication with VMware ESX.

If this option is omitted, the command uses HTTPS for communication.

-u *user-ID*

Specifies the user ID associated with the connection-target VMware ESX account.

The user ID must be a maximum of 256 characters. Neither the space nor the tab character can be specified.

-p *password*

Specifies the password for the user ID that was specified in the `-u` option.

The password must be a maximum of 256 characters. Neither the space nor the tab character can be specified.

If this option is omitted, the command assumes that there is no password.

–c *host-name* [*host-name*]

Specifies the names of hosts where VMware ESX is running. For a host name, specify a maximum of 255 characters. You can specify multiple host names by separating them with the space character or the tab delimiter.

–o *output-file-name*

Specifies the relative or absolute path name of the virtualization configuration information file that is to store the configuration information collected from VMware ESX. This option is mandatory. If the path contains a space, enclose the entire path in double-quotation marks ("").

## Return values

|    |                                                                              |
|----|------------------------------------------------------------------------------|
| 0  | Normal termination <sup>#1</sup>                                             |
| 1  | Argument error                                                               |
| 2  | Insufficient memory                                                          |
| 3  | JavaVM start error occurred                                                  |
| 4  | Execution permission error (Windows only)                                    |
| 5  | Command was not executed from the administrator console (Windows only)       |
| 6  | Output file already exists                                                   |
| 7  | Acquisition of virtualization configuration information failed <sup>#2</sup> |
| 8  | An input/output error occurred                                               |
| 99 | Other error                                                                  |

#1

The command terminates normally even when some of the virtualization configuration information has not been acquired.

#2

The command outputs a return value if it is unable to acquire virtualization configuration information from any host.

## Format of the virtualization configuration information file

Table 1–10: Header information (line 1)

| Item                                                                                | Output value |
|-------------------------------------------------------------------------------------|--------------|
| Identification character string for a virtualization configuration information file | #VM          |
| File format version                                                                 | 090100       |
| Character encoding                                                                  | UTF-8 fixed  |

Table 1–11: Output items (lines beginning with line 2)

| Item                 | Output value         |
|----------------------|----------------------|
| Host_name            | Host_name            |
| VMM_host_name        | VMM_host_name        |
| Virtual_manager_type | Virtual_manager_type |
| Manager_version      | Manager_version      |
| Virtual_host_manager | Virtual_host_manager |

Table 1–12: Output items (From line 3)

| Item                 | Description                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host name            | Host name                                                                                                                                                                                 |
| VMM host name        | Name of the host where virtualization environment software is run.<br>In the case of a VMM host with no guest OS, the virtual host name field is blank and only the VMM host name is set. |
| Virtual_manager_type | Type of product that manages the virtualization configuration: <ul style="list-style-type: none"> <li>• For VMware ESX: ESX</li> </ul>                                                    |
| Manager_version      | Version of the product that manages a virtualization configuration                                                                                                                        |
| Virtual_host_manager | Name of the host that manages the VMM host<br>For jcfcolvmesx: a space                                                                                                                    |

## Example output

```
#VM,090100,UTF-8
Host_name,VMM_host_name,Virtual_manager_type,Manager_version,Virtual_host_ma
nager
Vm1,ESX1,,,
Vm2,ESX1,,,
ESX1,,ESX,4.0,
```

## Function

This command acquires virtualization configuration information from HCSM, and outputs it to a virtualization configuration information file.

For details about the prerequisite conditions for executing this command, see *3.3.1(1) Prerequisites for managing a virtualization configuration* in the *JPI/Integrated Management 3 - Manager Configuration Guide*.

## Format

```
jcfcolvmhcsn
    -u user-ID
    -p password
    [-port port-number]
    -c host-name [host-name]
    -o output-file-name
```

## Execution permission

In Windows: Administrators permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

-u *user-ID*

Specifies the user ID of a connection-destination HCSM account. Specify a character string with a maximum of 255 bytes, excluding control characters, for the user ID.

-p *password*

Specifies the password for the user ID that is specified in the -u option. Specify a character string with a maximum of 255 bytes, excluding control characters, for the password.

-port *port-number*

Specifies the port number for communicating with the connection destination HCSM. Specify a numeric value with one-byte characters from 1 to 65535. If you omit this option, 23015 is assumed.

-c *host-name* [*host-name*]

Specifies the names of hosts where HCSM is running. For a host name, specify a maximum of 255 characters. You can specify multiple host names by separating them with the space character or the tab delimiter.

–○ *output-file-name*

Specifies the relative or absolute path name of the virtualization configuration information file that is to store the configuration information acquired from HCSM. This option is mandatory. If the path contains a space, enclose the entire path in double-quotation marks (").

## Return values

|    |                                                                              |
|----|------------------------------------------------------------------------------|
| 0  | Normal termination <sup>#1</sup>                                             |
| 1  | Argument error                                                               |
| 2  | Insufficient memory                                                          |
| 3  | JavaVM start error occurred                                                  |
| 4  | Execution permission error                                                   |
| 5  | Command was not executed from the administrator console                      |
| 6  | Output file already exists                                                   |
| 7  | Acquisition of virtualization configuration information failed <sup>#2</sup> |
| 8  | An input/output error occurred                                               |
| 99 | Other error                                                                  |

#1

The command terminates normally even when some of the virtualization configuration information has not been acquired.

#2

The command outputs a return value if it is unable to acquire virtualization configuration information from any host.

## Format of the virtualization configuration information file

Table 1–13: Header information (line 1)

| Item                                                                                | Output value |
|-------------------------------------------------------------------------------------|--------------|
| Identification character string for a virtualization configuration information file | #VM          |
| File format version                                                                 | 101000       |
| Character encoding                                                                  | UTF-8 fixed  |

Table 1–14: Header information (line 2)

| Item                                         | Output value         |
|----------------------------------------------|----------------------|
| Host name                                    | Host_name            |
| VMM host name                                | VMM_host_name        |
| Virtualization management type               | Virtual_manager_type |
| Virtualization management product version    | Manager_version      |
| Virtualization configuration management host | Virtual_host_manager |

Table 1–15: Output items (From line 3)

| Item      | Description |
|-----------|-------------|
| Host name | Host name   |

| Item                                         | Description                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VMM host name                                | Name of the host where virtualization environment software is running.<br>In the case of a VMM host with no guest OS, the virtual host name field is blank and only the VMM host name is set.                                                                                                                                                                    |
| Virtualization management type               | Type of the product that manages the virtualization configuration:<br>For HCSM: HCSM<br>For Hitachi Compute Blade logical partitioning feature: Virtage                                                                                                                                                                                                          |
| Virtualization management product version    | Version of the product that manages a virtualization configuration.<br>When the virtualization management type is HCSM, the version of the external connection interface for HCSM is set.<br>Note that if virtualization configuration information is acquired from HCSM, no versions can be acquired on a host whose virtualization management type is Virtage. |
| Virtualization configuration management host | Name of the host that manages a VMM host                                                                                                                                                                                                                                                                                                                         |

## Example output

```

```

## Function

This command acquires virtualization configuration information from KVM, and outputs it to a virtualization configuration information file.

For details about the prerequisite conditions for executing this command, see *3.3.1(1) Prerequisites for managing a virtualization configuration* in the *JPI/Integrated Management 3 - Manager Configuration Guide*.

## Format

```
jcfcolvmkvm
    -u user-ID
    -i private-key-file-path
    [-port port-number]
    -c host-name [host-name]
    -o output-file-name
```

## Execution permission

In Windows: Administrators permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

**-u** *user-ID*

Specifies the user ID of the host where the connection destination KVM is running. Specify a character string with a maximum of 255 bytes, excluding control characters, for the user ID.

**-i** *private-key-file-path*

Specifies the name of the private key file that is used to communicate with the connection destination KVM in absolute path format. Specify a character string with a maximum of 256 bytes, excluding control characters, for the private key file. The private key file path is case sensitive. If the path contains a space, enclose the entire path in double-quotation marks (").

**-port** *port-number*

Specifies the port number for an SSH connection with the connection destination KVM. Specify a numeric value with one-byte characters from 1 to 65535. If you omit this option, 22 is assumed.

**-c** *host-name* [*host-name*]

Specifies the names of hosts where KVM is running. For a host name, specify a maximum of 255 characters. You can specify multiple host names by separating them with the space character or the tab delimiter.

–○ *output-file-name*

Specifies the relative or absolute path name of the virtualization configuration information file that is to store the configuration information acquired from KVM. This option is mandatory. If the path contains a space, enclose the entire path in double-quotation marks (").

## Return values

|    |                                                                              |
|----|------------------------------------------------------------------------------|
| 0  | Normal termination <sup>#1</sup>                                             |
| 1  | Argument error                                                               |
| 2  | Insufficient memory                                                          |
| 3  | JavaVM start error occurred                                                  |
| 4  | Execution permission error                                                   |
| 5  | Command was not executed from the administrator console                      |
| 6  | Output file already exists                                                   |
| 7  | Acquisition of virtualization configuration information failed <sup>#2</sup> |
| 8  | An input/output error occurred                                               |
| 99 | Other error                                                                  |

#1

The command terminates normally even when some of the virtualization configuration information has not been acquired.

#2

The command outputs a return value if it is unable to acquire virtualization configuration information from any host.

## Format of the virtualization configuration information file

Table 1–16: Header information (line 1)

| Item                                                                                | Output value |
|-------------------------------------------------------------------------------------|--------------|
| Identification character string for a virtualization configuration information file | #VM          |
| File format version                                                                 | 101000       |
| Character encoding                                                                  | UTF-8 fixed  |

Table 1–17: Header information (line 2)

| Item                                         | Output value         |
|----------------------------------------------|----------------------|

kv7803,jpl-sf7800b,,,
kv7804,jpl-sf7800b,,,
```

# jcfcvmscvm (Windows only)

---

## Function

This command acquires virtualization configuration information from SCVMM and outputs it to a virtualization configuration information file.

For details about the prerequisite conditions for executing this command, see *3.3.1(1) Prerequisites for managing a virtualization configuration* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

## Format

```
jcfcvmscvm
  -c host-name [host-name]
    [-d domain name -u user-ID[-p password]]
  -o output-file-name
```

## Execution permission

Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

## Storage directory

*Manager-path*\bin\imcf\

## Arguments

-c *host-name* [*host-name*]

Specifies the names of hosts where SCVMM is running. For a host name, specify a maximum of 255 characters. You can specify multiple host names by separating them with the space character or the tab delimiter.

-d *domain name*

Specifies the name of the domain to which the connection-target SCVMM host belongs. This option can be omitted if JP1/IM - Manager belongs to the same domain as that of the connection-target SCVMM host. For a domain name, specify a maximum of 255 characters.

-u *user-ID*

Specifies the user ID of the administrator permission account for the domain to which the connection-target SCVMM host belongs. This option is optional, but if you specify the -d option, you must also specify this option. Specify a character string with a maximum of 255 bytes, excluding control characters, for the user ID.

-p *password*

Specifies the password for the user ID that is specified in the -u option. If this option is omitted, the command assumes that there is no password. Specify a character string with a maximum of 255 bytes, excluding control characters, for the password.

-o *output-file-name*

Specifies the name of the virtualization configuration information file that stores the configuration information obtained from vCenter in relative path or absolute path format. If the path contains a space, enclose the entire path in double-quotation marks (").

## Return values

|    |                                                                              |
|----|------------------------------------------------------------------------------|
| 0  | Normal termination <sup>#1</sup>                                             |
| 1  | Argument error                                                               |
| 2  | Insufficient memory                                                          |
| 3  | JavaVM start error occurred                                                  |
| 4  | Execution permission error                                                   |
| 5  | Command was not executed from the administrator console                      |
| 6  | Output file already exists                                                   |
| 7  | Acquisition of virtualization configuration information failed <sup>#2</sup> |
| 8  | An input/output error occurred                                               |
| 99 | Other error                                                                  |

#1

The command terminates normally even when some of the virtual configuration information has not been acquired.

#2

The command outputs a return value if it is unable to acquire virtualization configuration information from any host.

## Format of the virtualization configuration information file

Table 1–19: Header information (line 1)

| Item                                                                                | Description of output value |
|-------------------------------------------------------------------------------------|-----------------------------|
| Identification character string for a virtualization configuration information file | #VM                         |
| File format version                                                                 | 090100                      |
| Character encoding                                                                  | UTF-8 fixed                 |

Table 1–20: Header information (line 2)

| Item                 | Description of output value |

Vm2,ESX1,,,
ESX1,,ESX,4.0,vCenter1
vCenter1,, vCenter,2.0,SCVMM1
SCVMM1,, SCVMM,2008,
```

## Function

Obtains virtualization configuration information from vCenter, and outputs it to a virtualization configuration information file.

For details about the prerequisite conditions for executing this command, see *3.3.1(1) Prerequisites for managing a virtualization configuration* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

## Format

```
jcfcolvmvc
    [-m communication-type]
    -u user-ID
    [-p password]
    -c host-name [host-name]
    -o output-file-name
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

**-m** *communication-type*

Specifies the method of communication with vCenter.

When `https` is specified, https communication is used for communication with vCenter. When `http` is specified, http communication is used for communication with vCenter.

If this option is omitted, https communication is used.

**-u** *user-ID*

Specifies the user ID of a connection-target vCenter account.

Specify a character string with a maximum of 255 bytes, excluding control characters, for the user ID.

**-p** *password*

Specifies the password for the user ID that is specified in the `-u` option.

Specify a character string with a maximum of 255 bytes, excluding control characters, for the password.

If this option is omitted, the command assumes that there is no password.

–c *host-name* [*host-name*]

Specifies the names of the hosts where vCenter is running. For a host name, specify a maximum of 255 characters. You can specify multiple host names by separating them with the space character or the tab delimiter.

–o *output-file-name*

Specifies the name of the virtualization configuration information file that stores the configuration information obtained from vCenter in relative path or absolute path format. If the path contains a space, enclose the entire path in double-quotation marks (").

## Return values

|    |                                                                              |
|----|------------------------------------------------------------------------------|
| 0  | Normal termination <sup>#1</sup>                                             |
| 1  | Argument error                                                               |
| 2  | Insufficient memory                                                          |
| 3  | JavaVM start error occurred                                                  |
| 4  | Execution permission error                                                   |
| 5  | The command was not executed from the administrator console                  |
| 6  | Output file already exists                                                   |
| 7  | Acquisition of virtualization configuration information failed <sup>#2</sup> |
| 8  | Input/output error                                                           |
| 99 | Other error                                                                  |

#1

The command terminates normally even when some of the virtual configuration information has not been acquired.

#2

The command outputs a return value if it is unable to acquire virtualization configuration information from any host.

## Format of the virtualization configuration information file

Table 1–22: Header information (line 1)

| Item                                                                                | Output value |
|-------------------------------------------------------------------------------------|--------------|
| Identification character string for a virtualization configuration information file | #VM          |
| File format version                                                                 | 090100       |
| Character encoding                                                                  | UTF-8 fixed  |

Table 1–23: Header information (line 2)

| Item                                         | Output value         |
|----------------------------------------------|----------------------|
| Host name                                    | Host_name            |
| VMM host name                                | VMM_host_name        |
| Virtualization management type               | Virtual_manager_type |
| Virtualization management product version    | Manager_version      |
| Virtualization configuration management host | Virtual_host_manager |

Table 1–24: Output items (From line 3)

| Item                                       | Description                                                                                                                                                                             |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host name                                  | Host name                                                                                                                                                                               |
| VMM host name                              | Name of the host where virtualization environment software runs.<br>In the case of a VMM host with no guest OS, the virtual host name field is blank and only the VMM host name is set. |
| Virtualization management type             | Type of product that manages the virtualization configuration: <ul style="list-style-type: none"> <li>• For vCenter: vCenter</li> <li>• For VMware ESX: ESX</li> </ul>                  |
| Virtualization management product version  | Version of the product that manages a virtualization configuration                                                                                                                      |
| Virtualization management former host name | Name of the host that manages a VMM host                                                                                                                                                |

## Example output

```
#VM,090100,UTF-8
Host_name,VMM_host_name,Virtual_manager_type,Manager_version,Virtual_host_ma
nager
Vm1,ESX1,,,
Vm2,ESX1,,,
ESX1,,ESX,4.0,vCenter1
vCenter1,, vCenter,2.0,
```

## Function

This command acquires virtualization configuration information from Hitachi Compute Blade logical partitioning feature and outputs it to a virtualization configuration information file.

For the prerequisite conditions for executing this command, see *3.3.1(1) Prerequisites for managing a virtualization configuration* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

## Format

```
jcfcolvmvirtage
    -c host-name [host-name]
    -o output-file-name
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command is executed from the administrator console.)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

-c *host-name* [*host-name*]

Specifies the name of the host where JP1/SC/CM that manages Hitachi Compute Blade logical partitioning feature is running. For a host name, specify a maximum of 255 characters. You can specify multiple host names by separating them with the space character or the tab delimiter.

-o *output-file-name*

Specifies the virtualization configuration information file that stores the configuration information obtained from JP1/SC that manages Hitachi Compute Blade logical partitioning feature in relative path or absolute path format. This option cannot be omitted. If the path contains a space, enclose the entire path in double-quotation marks (").

## Return values

|   |                                                             |
|---|-------------------------------------------------------------|
| 0 | Normal termination <sup>#1</sup>                            |
| 1 | Argument error                                              |
| 2 | Insufficient memory                                         |
| 3 | JavaVM start error occurred                                 |
| 4 | Execution permission error                                  |
| 5 | The command was not executed from the administrator console |

1. Commands

|    |                                                                              |
|----|------------------------------------------------------------------------------|
| 6  | Output file already exists                                                   |
| 7  | Acquisition of virtualization configuration information failed <sup>#2</sup> |
| 8  | Input/output error                                                           |
| 99 | Other error                                                                  |

#1

The command terminates normally even when some of the virtual configuration information has not been acquired.

#2

The command outputs a return value if it is unable to acquire virtualization configuration information from any host.

## Format of the virtualization configuration information file

Table 1–25: Header information (line 1)

| Item                                                                                | Output value |
|-------------------------------------------------------------------------------------|--------------|
| Identification character string for a virtualization configuration information file | #VM          |
| File format version                                                                 | 090100       |
| Character encoding                                                                  | UTF-8 fixed  |

Table 1–26: Header information (line 2)

| Item                                         | Output value         |
|----------------------------------------------|----------------------|
| Host name                                    | Host_name            |

| Virtualization management former host name | Name of the host that manages a VMM host                                                                                                                                                                           |

## Example output

```
#VM,090100,UTF-8
Host_name,VMM_host_name,Virtual_manager_type,Manager_version,Virtual_host_ma
nager
```

```
Vm1,VIRTAGE1,,,  
Vm2, VIRTAGE1,,,  
VIRTAGE1,,Virtage,  
SCCM1,VIRTAGE1,JP1/SC/CM,,
```

# jcfdbsetup

---

## Function

This command sets up the IM Configuration Management database for storing configuration information. You must have already specified in advance in the setup information file the database's size, port number, and storage location.

In Windows, if this command is executed in an environment where the integrated monitoring database is not set up, the following services are registered in the OS:

- When setting up a physical host: JP1/IM3-Manager DB Server, JP1/IM3-Manager DB Cluster Service
- When setting up a cluster configuration: JP1/IM3-Manager DB Server\_*logical-host-name*, JP1/IM3-Manager DB Cluster Service\_*logical-host-name*

In UNIX, if this command is executed in an environment where the integrated monitoring database is not set up, an entry containing the path to the IM database is added to the `/etc/inittab` file. The entry is added to the respective physical and logical hosts on which the command was executed. Do not delete, edit, or comment out the entry in the `/etc/inittab` file that is added when this command is executed.

## Format

```
jcfdbsetup {-f setup-information-file-name|-s}  
           [-h logical-host-name -c {online|standby}]  
           [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdb\

In UNIX:

/opt/jplimm/bin/imdb/

## Arguments

`-f setup-information-file-name`

Specifies the setup information file that contains the requisite information, such as the installation folder and the size of the database area. If neither an IM Configuration Management database nor an integrated monitoring database has been set up, you must specify this option. If the integrated monitoring database has already been set up, specify in this option the setup information file that you specified when you set up the integrated monitoring database. Alternatively, if the integrated monitoring database has already been set up, you can specify the `-s` option instead. In such a case, the command uses the setup information that was specified when the integrated monitoring database was set up.

This option cannot be specified together with the `-s` option. Additionally, the `-f` and `-s` options cannot both be omitted.

If the path contains a space, enclose the entire path in double-quotation marks ("). If you configure a cluster environment, specify the cluster setup information file name.

-s

If the integrated monitoring database has already been set up, you can specify this option instead of the -f option. When this option is specified, the command sets up the IM Configuration Management database using the setup information that was specified when the integrated monitoring database was set up.

If the integrated monitoring database has not been set up but this option is specified, the command displays the KNAN11193-E message.

This option cannot be specified together with the -f option. Additionally, the -s and -f options cannot both be omitted.

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host that executes the command. The command sets up the IM Configuration Management database for the specified logical host. If you do not use a cluster system, specification of this option is not needed. Note that this logical host name cannot be JP1\_DEFAULT. In addition, the logical host name is case sensitive. For the logical host name, specify a logical host name set in JP1/Base in the correct form, especially case.

-c {online|standby}

Specifies the setup type in the cluster configuration (primary node or secondary node). If you have specified the -h option, you must specify this option. In addition, if the integrated monitoring database has already been set up on the same host, for the -c option, specify the same value that you used when you created the integrated monitoring database.

- **online**: Specifies that the primary node is to be set up.
- **standby**: Specifies that the secondary node is to be set up.

If you specify **online**, mount the shared disk and establish a connection to the logical host. If you are running a logical host in a non-cluster environment, specify **online** in the -c option.

-q

Specifies that the command is to be executed without requesting confirmation from the user.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Notes

- The contents of the cluster setup information files must be identical between the primary and secondary nodes. When you set up the secondary node, copy the cluster setup information file used for the primary node and then use that file. If the contents of the files specified for the primary and secondary nodes are different, cancel the setup at the secondary node, copy the cluster setup information file from the primary node, and then re-execute the command.
- If you execute the command with the -c option specified, do not switch servers during execution. If you switch servers during execution, cancel the setup after the command has terminated, and then re-execute the command.
- If you have canceled the command's execution by pressing **Ctrl + C** or **Ctrl + Break**, make sure that the **pdistup**, **pdfmkfs**, **pddef**, and **pdload** processes are not executing, execute the **jcfdbunsetup** command, and then re-execute this command.
- If the integrated monitoring database has already been set up and the IM database is being used, JP1/IM - Manager Service must be stopped.

- If you are using the integrated monitoring database in Windows, the IM database (JP1/IM3-Manager DB Server) must be running and the cluster service for the IM database (JP1/IM3-Manager DB Cluster Service\_*logical-host-name*) must be stopped.
- If you are using JP1/IM - MO, the JP1/IM - Message Optimizer service of JP1/IM - MO on the connection source must be stopped.
- Before executing the command, verify that the logical host name specified in the argument matches the JP1/Base logical host name, and that the logical host name can be resolved.
- If you cancel setup of the IM database by executing the `jcodbunsetup` or `jcfdbunsetup` command, you must restart the OS before re-executing the `jcfdbsetup` command.
- Before executing the command in Windows , in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.

# jcfdbunsetup

---

## Function

This command cancels setup of the IM Configuration Management database that stores configuration information.

Execute this command when you stop using the IM Configuration Management database, uninstall JP1/IM - Manager, re-create the IM Configuration Management database, or expand the database size.

In an environment in which an integrated monitoring database has been set up, the integrated monitoring database is still available even after execution of this command.

In Windows, if this command is executed in an environment where the integrated monitoring database is not set up, the following services are deleted:

- When removing setup of a physical host: JP1/IM-Manager DB Server, JP1/IM-Manager DB Cluster Service
- When removing setup of a cluster configuration: JP1/IM-Manager DB Server\_*logical-host-name*, JP1/IM-Manager DB Cluster Service\_*logical-host-name*

In UNIX, if this command is executed in an environment where the integrated monitoring database is not set up, entries in the `/etc/inittab` file registered by the `jcodbsetup` or `jcfdbsetup` command are deleted. The entries that are deleted are only those for processing related to the physical and logical hosts on which the command was executed.

Note that the following files must be deleted after the `jcfdbunsetup` command has been executed.

In Windows:

For a physical host:

*Manager-path\data\imcf\file-under-imconfig*  
*Manager-path\data\imcf\file-and-folder-under-profiles*

For a logical host:

*shared-folder\data\imcf\file-under-imconfig*  
*shared-folder\data\imcf\file-and-folder-under-profiles*

In UNIX:

For a physical host:

*/var/opt/jplimm/data/imcf/file-under-imconfig*  
*/var/opt/jplimm/data/imcf/file-and-folder-under-profiles*

For a logical host:

*shared-directory/data/imcf/file-under-imconfig*  
*shared-directory/data/imcf/file-and-directory-under-profiles*

## Format

```
jcfdbunsetup [-h logical-host-name -c {online|standby}]  
              [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdb\

In UNIX:

/opt/jp1imm/bin/imdb/

## Arguments

**-h** *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host that executes the command. The command cancels setup of the IM Configuration Management database for the specified logical host. If you do not use a cluster system, specification of this option is not needed. Note that this logical host name cannot be JP1\_DEFAULT. In addition, the logical host name is case sensitive. For the logical host name, specify a logical host name set in JP1/Base in the correct form, especially case.

**-c** {online|standby}

Specifies the type of setup being canceled in the cluster configuration (primary node or secondary node). If you have specified the **-h** option, you must specify this option.

- **online**: Specify this value if you specified **online** during setup of the IM Configuration Management database.
- **standby**: Specify this value if you specified **standby** during setup of the IM Configuration Management database.

If you specify **online**, mount the shared disk and establish a connection to the logical host. If you cancel setup of the IM Configuration Management database on a logical host that was running in a non-cluster environment, specify **online** in the **-c** option.

**-q**

Specifies that the command is to be executed without requesting confirmation from the user.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Notes

- If you want to expand the database size in an environment where the integrated monitoring database has been created, you must execute the command for performing unsetup of the integrated monitoring database after executing the **jcfd bunsetup** command.
- If you execute this command with the **-c** option specified, do not switch servers during execution. If you switch servers during execution, re-execute the command after it has terminated.
- If you have canceled the command's execution by pressing **Ctrl + C** or **Ctrl + Break**, make sure that the **pdirst** process is not executing, and then re-execute this command.
- In Windows, services must be in the following status:

For the physical host:

The cluster service for the IM database (JP1/IM3-Manager DB Cluster Service) must have stopped, and the IM database service (JP1/IM3-Manager DB Server) must have started. In addition, when the integrated monitoring database has been set up and the IM database is being used, the JP1/IM - Manager service (JP1/IM3-Manager) must have stopped.

For the logical host:

The cluster service for the IM database (JP1/IM3-Manager DB Cluster Service\_*logical-host-name*) on the logical host must be stopped, and the IM database service (JP1/IM3-Manager DB Server\_*logical-host-name*) on the logical host must be started. In addition, if the integrated monitoring database has been set up and the IM database is being used, the JP1/IM - Manager service (JP1/IM3-Manager\_*logical-host-name*) must be stopped.

- In UNIX, when the IM Configuration Management database has been set up and the IM database is being used, the JP1/IM-Manager service must have stopped.
- If you are using JP1/IM - MO, the JP1/IM - Message Optimizer service of JP1/IM - MO on the connection source must be stopped.
- Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.

## Function

This command outputs the hierarchy configuration (IM configuration) of the system managed by IM Configuration Management, host information, and definition information.

When you execute this command, the three types of information (host, system hierarchy, and profiles) that have been managed by IM Configuration Management before import processing are all deleted and then the specified information is imported.

To use this command, IM Configuration Management Service must be running. This command cannot be executed while the `jcfimport` command is executing. A maximum of five commands can be executed concurrently.

## Format

```
jcfexport      [-h logical-host-name]  
               [-f]  
               -o directory-name  
               [-m | -r | -c | -g | -a]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host that executes the command. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-f

Specifies that the file is to be overwritten if the specified directory already contains a file with the same name as the export file. If this option is omitted and the export target already contains a file with the same name, the information is not exported.

-o *directory-name*

Specifies the name of the directory to which the export data is to be output, expressed as an absolute path or a path relative to the location where the command is executed. This option is mandatory. If the path contains a space, enclose the entire path in double-quotation marks (").

-m

Specifies that only the host information is to be exported. The exported information is output to the host input information file (`host_input_data.csv`).

This option cannot be specified together with the `-r`, `-c`, `-g`, or `-a` option. If all of the `-m`, `-r`, `-c`, `-g`, and `-a` options are omitted, the `-a` option is assumed.

-r

Only host information and remote authentication information are exported.

This option cannot be specified together with the `-m`, `-c`, `-g`, or `-a` option. If specified in such a case, an invalid argument error results. If all of the `-m`, `-r`, `-c`, `-g`, and `-a` options are omitted, the `-a` option is assumed.

-c

Specifies that only the host information and the system hierarchy information is to be exported. The host information is output to the host input information file (`host_input_data.csv`), and the system hierarchy is output to `system_tree_information.txt`.

This option cannot be specified together with the `-m`, `-r`, `-g`, or `-a` option. If specified in such a case, an invalid argument error results. If you omit all of the `-m`, `-c`, and `-a` options, the `-a` option is assumed. If all of the `-m`, `-r`, `-c`, `-g`, and `-a` options are omitted, the `-a` option is assumed.

-g

Only host information, business group information, and monitoring group information are exported.

This option cannot be specified together with the `-m`, `-r`, `-c`, or `-a` option. If specified in such a case, an invalid argument error results. If all of the `-m`, `-r`, `-c`, `-g`, and `-a` options are omitted, the `-a` option is assumed.

-a

Specifies that all three types of information are to be exported. The exported information is output to `data_information.txt`. The host information is output to the host input information file (`host_input_data.csv`), the system hierarchy is output to `system_tree_information.txt`, and the definition information is output to the following files directly under *directory-specified-in--o-option*\definition\_files\host-name\product-name:

- Forwarding settings file (`forward`)
- The action definition file of a log file trap (an arbitrary file)
- Log file trap startup definition file (`jvlog_start.conf`)
- Event log trapping function operation definition file (`nthevent.conf`)
- Location action definition file (`jbslcact.conf`)

This option cannot be specified together with the `-m`, `-r`, `-c`, or `-g` option. If specified in such a case, an invalid argument error results. If all of the `-m`, `-r`, `-c`, `-g`, and `-a` options are omitted, the `-a` option is assumed.

## Notes

- For hosts where no profile configuration file is collected, there is no data to be exported (and no directory is created).
- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.

If you execute with standby host in UNIX / Linux, an unwanted directory named */shared-directory-name* is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- */shared-directory-name/jplimm*

- `/shared-directory-name/jplimm/log`
- `/shared-directory-name/jplimm/log/imcf`

Delete these unwanted directory and files, they will never to be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|                |                                                                   |
|----------------|-------------------------------------------------------------------|
| 0              | Normal termination                                                |
| 4              | Invalid option                                                    |
| 8              | Server cannot be connected                                        |
| 12             | Memory shortage occurred                                          |
| 16             | Invalid permission                                                |
| 20             | Error, such as a file error, invalid path, or file already exists |
| 21             | Upper limit for number of concurrent executions reached           |
| 24             | An input/output error occurred                                    |
| 120            | System error occurred                                             |
| 124            | Terminated due to other error                                     |
| 201 or greater | JavaVM start error occurred                                       |

## Example

Export all IM Configuration Management information to the directory under `c:\temp`:

```
jcfexport -o c:\temp
```

## Function

This command imports IM Configuration Management information.

You cannot use this command unless IM Configuration Management Service is running. Note that this command cannot be executed during remote monitoring. In addition, a maximum of five commands can be executed concurrently.

Executing this command deletes three types of information (host, system hierarchy (IM configuration), and profile) that have been managed by IM Configuration Management before import processing. Thereafter, the information specified by options is imported.

To perform remote monitoring after the import, open the System Common Settings window from the IM Configuration Management - View, review the settings, and then click the **OK** button.

## Format

```
jcimport  [-h logical-host-name]  
          -i directory-name  
          [-m | -r | -c | -g | -a]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host that executes the command. If this option is omitted, the command assumes the logical host name specified in the JP1\_HOSTNAME environment variable. If the JP1\_HOSTNAME environment variable is not specified, the command assumes the physical host name. If you do not use a cluster system, there is no need to specify this option.

-i *directory-name*

Specifies the name of the directory to which files were exported by the jcfexport command, expressed as an absolute path or a path relative to the location where the jcimport command is executed. This option is mandatory.

-m

Specifies that only the host information is to be imported. This option cannot be specified together with the -c, -r, -g, or -a option. If specified in such a case, an invalid argument error results. If all of the -m, -r, -c, -g, and -a options are omitted, the -a option is assumed.

-r

Imports only host information and remote authentication information.

This option cannot be specified together with the -m, -c, -g, or -a option. If specified in such a case, an invalid argument error results. If all of the -m, -r, -c, -g, and -a options are omitted, the -a option is assumed.

-c

Specifies that the system hierarchy and host information are to be imported. This option cannot be specified together with the -m or -a option. If specified in such a case, an invalid argument error results. If you omit all of the -m, -c, and -a options, the -a option is assumed.

-g

Imports host information, business group information, and monitoring group information only.

This option cannot be specified together with the -m, -r, -c, or -a option. If specified in such a case, an invalid argument error results. If all of the -m, -r, -c, -g, and -a options are omitted, the -a option is assumed.

-a

Specifies that all information is to be imported. This option cannot be specified together with the -m, -r -c, or -g option. If specified in such a case, an invalid argument error results. If all of the -m, -r, -c, -g, and -a options are omitted, the -a option is assumed.

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.

If you execute with standby host in UNIX / Linux, an unwanted directory named */shared-directory-name* is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- */shared-directory-name/jplimm*
- */shared-directory-name/jplimm/log*
- */shared-directory-name/jplimm/log/imcf*

Delete these unwanted directory and files, they will never be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|     |                                                         |
|-----|---------------------------------------------------------|
| 0   | Normal termination                                      |
| 4   | Invalid option                                          |
| 8   | Server cannot be connected                              |
| 12  | Memory shortage occurred                                |
| 16  | Invalid permission                                      |
| 20  | Error, such as a file error or invalid path             |
| 21  | Upper limit for number of concurrent executions reached |
| 24  | An input/output error occurred                          |
| 120 | System error occurred                                   |
| 124 | Terminated due to other error                           |

|                |                             |
|----------------|-----------------------------|
| 201 or greater | JavaVM start error occurred |
|----------------|-----------------------------|

## Example

Import all the data of an export file located under the `c:\temp`:

```
jcfimport -i c:\temp
```

## Function

This command creates from the host input information file (`host_input_data.csv`) and the Central Scope export file a Central Scope import file that contains monitoring tree information for a virtualization configuration. Alternatively, the command creates from the business group information file (`monitoring_system_data.csv`), the monitoring group information file (`monitoring_group_data.csv`), and the Central Scope export file a Central Scope import file to which the monitoring tree information of a business group is added.

For details about the business group information file (`monitoring_system_data.csv`) and the monitoring group information file (`monitoring_group_data.csv`), see 9.7.1(5) *Business group information* and 9.7.1(6) *Monitoring group information* in the *JPI/Integrated Management 3 - Manager Administration Guide*.

## Format

```
jcfmkcsdata
    { -f host-input-information-file-name Central-Scope's-export-file
-name | -g business-group-information-file-name monitoring-group-information
-file-name Central-Scope's-export-file-name }
    -o export-file-name
    [-r]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

**-f** *host-input-information-file-name Central-Scope's-export-file-name*

Specifies the relative or absolute path of the host input information file (`host_input_data.csv`) exported by the `jcfexport` command and of the file exported by the `jcsdbexport` command. This option cannot be specified together with the `-g` option. If a path contains a space, enclose the entire path in double-quotation marks (").

For the Central Scope's export file, specify the file to which a server-oriented tree has been exported.

For details about the host input information file (`host_input_data.csv`), see 9.7.1(1) *Host information* in the *JPI/Integrated Management 3 - Manager Administration Guide*.

**-g** *business-group-information-file-name monitoring-group-information-file-name Central-Scope's-export-file-name*

Specifies the business group information file exported by using the `jcfexport` command (`monitoring_system_data.csv`), the monitoring group information file

(`monitoring_group_data.csv`), and the file exported by using the `jcsdbexport` command, expressed as a relative path or an absolute path. This option cannot be specified together with the `-f` option. If the path contains a space, enclose the entire path in double-quotation marks (").

For the Central Scope's export file, specify the file to which a server-oriented tree was exported. Note that for the export file, specify a file exported from the monitoring object DB whose data version is 0810 or later.

–o *export-file-name*

Specifies the relative or absolute path of the Central Scope import file that is to be output by the command. This option is mandatory. If the path contains a space, enclose the entire path in double-quotation marks (").

[*-r*]

This option sets whether to use the virtualization system configuration tree contained in the JP1/IM - Manager (Central Scope) export file specified by the argument. When this option is specified, the command creates a new file without using the virtualization system configuration tree contained in the JP1/IM - Manager (Central Scope) export file. If this option is not specified, a new virtualization system configuration tree is added to the virtualization system configuration tree contained in the JP1/IM - Manager (Central Scope) export file.

## Return values

|     |                                                                        |
|-----|------------------------------------------------------------------------|
| 0   | Normal termination                                                     |
| 1   | Argument error                                                         |
| 2   | Specified file is invalid                                              |
| 3   | Specified input file was not found                                     |
| 4   | Export file already exists                                             |
| 5   | No permission to access a specified file                               |
| 6   | Insufficient memory                                                    |
| 7   | An input/output error occurred                                         |
| 9   | Insufficient disk space                                                |
| 10  | Execution permission error                                             |
| 11  | Forced termination by pressing the <b>Ctrl</b> and <b>C</b> keys       |
| 12  | The data version of the specified Central Scope export file is old     |
| 20  | A reserved device was specified for the file path                      |
| 99  | Other error                                                            |
| 122 | Command was not executed from the administrator console (Windows only) |

## Function

This command uses a virtualization configuration information file to update a host input information file.

## Format

```
jcfmkhostsdata
    -imcf host-input-information-file
    -vm virtualization-configuration-information-file
    -o output-file-name
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

**-imcf** *host-input-information-file*

Specifies the relative or absolute path name of the host input information file. This option is mandatory. If the path contains a space, enclose the entire path in double-quotation marks (").

**-vm** *virtualization-configuration-information-file*

Specifies the relative or absolute path name of the virtualization configuration information file. This option is mandatory. If the path contains a space, enclose the entire path in double-quotation marks (").

**-o** *output-file-name*

Specifies the relative or absolute path name of the host input information file to which the result of updating the host input information file is to be output. This option is mandatory. If the path contains a space, enclose the entire path in double-quotation marks (").

## Return values

|   |                                                                        |
|---|------------------------------------------------------------------------|
| 0 | Normal termination                                                     |
| 1 | Argument error                                                         |
| 2 | Insufficient memory                                                    |
| 3 | JavaVM start error occurred                                            |
| 4 | Execution permission error (Windows only)                              |
| 5 | Command was not executed from the administrator console (Windows only) |

|    |                                          |
|----|------------------------------------------|
| 6  | Output file already exists               |
| 7  | A specified file is invalid              |
| 8  | A specified input file was not found     |
| 9  | No permission to access a specified file |
| 10 | An input/output error occurred           |
| 99 | Other error                              |

## jcftthreaddmp (Windows only)

---

### Function

This command creates a Java thread dump of IM Configuration Management - View.

Execute this command to collect a Java thread dump under the following circumstances:

- Window operation has become disabled.
- There are no stopped IM Configuration Management - View processes or IM Configuration Management server processes.

The command outputs a Java thread dump of IM Configuration Management - View to a text file in the `log` directory:

```
%ALLUSERSPROFILE%\Hitachi\JP1\JP1_DEFAULT\JP1CoView\log
```

If you create a thread dump of IM Configuration Management - View while it is running normally, JavaVM will become unstable, in which case you will have to restart IM Configuration Management - View.

### Format

```
jcftthreaddmp process-ID
```

### Execution permission

None (if the Windows UAC feature is enabled, the command is executed from the administrator console)

### Storage directory

*View-path*\bin\

### Arguments

*process-ID*

Specifies the process ID of the `java.exe` process of IM Configuration Management - View that has become disabled.

The number of binds that can be specified by the process ID depends on OS limitations.

`CTRL_BREAK_EVENT` is not sent to a process other than IM Configuration Management - View (`java.exe`).

### Return values

|    |                                               |
|----|-----------------------------------------------|
| 0  | Normal termination                            |
| 1  | Open error or argument error                  |
| 2  | Process check error                           |
| 3  | Thread dump output request transmission error |
| 4  | Execution permission error                    |
| 10 | Other error                                   |

## Example 1

The process ID of the IM Configuration Management - View that is disabled is 1234:

```
jcftthreaddmp 1234
```

## Example 2

Identify the process ID of the `java.exe` process that corresponds to the IM Configuration Management - View:

Use the procedure below to identify the process ID of the `java.exe` process that corresponds to the disabled IM Configuration Management - View and then specify that process ID in the `jcftthreaddmp` command.

If you are running multiple instances of IM Configuration Management - View, there are also multiple `java.exe` processes. In such a case, you use the procedure described below to identify the process ID.

1. Add a **PID (Process Identifier)** column.

Open Task Manager's **Process** page, from the **View** menu choose **Select Columns**, and then select the **PID (Process Identifier)** check box in the Select Columns dialog box.

2. Check whether the relevant IM Configuration Management - View instance is disabled.

On the Task Manager's **Applications** page, select IM Configuration Management - View. From the right-click pop-up menu, choose **Bring to Front**. Check if the IM Configuration Management - View displayed in front is disabled.

3. Display the PID (process identifier) of the `java.exe` process that corresponds to the disabled IM Configuration Management - View.

On the **Applications** page, select the disabled IM Configuration Management - View, and then from the right-click pop-up menu, choose **Go To Process**.

The **Processes** page is displayed and the `java.exe` line of the disabled IM Configuration Management - View is selected. The PID column of that line is the process ID of the `java.exe` process that corresponds to the disabled IM Configuration Management - View.

# jddcreatetree

---

## Function

This command collects system configuration information from products managed by the Intelligent Integrated Management server to create the IM management node-related files, which in turn are input to the `jddupdatetree` command. Before you can execute this command, you must execute the `jddsetaccessuser` command to set a user ID and password that are required for authentication.

For details about the `jddupdatetree` and `jddsetaccessuser` commands, see [jddupdatetree](#) and [jddsetaccessuser](#) in *Chapter 1. Commands*.

This command requests the Intelligent Integrated Management Base to create the IM management node-related files and waits until the request is completed.

Before you can execute this command, you must complete definitions in the following files: system node definition file (`imdd_systemnode.conf`), category name definition file for IM management nodes (`imdd_category_name.conf`), and target host definition file for configuration collection (`imdd_target_host.conf`). Additionally, you must complete the host name definition file (`imdd_host_name.conf`) for mapping between aliases and real host names if you want IM management nodes to include products that can have aliases for host names.

For details about the IM management node-related files, see the section that describes the IM management node-related files in the *JPI/Integrated Management 3 - Manager Overview and System Design Guide*.

For details about the definition files, see [System node definition file \(`imdd\_systemnode.conf`\)](#), [Category name definition file for IM management nodes \(`imdd\_category\_name.conf`\)](#), [Target host definition file for configuration collection \(`imdd\_target\_host.conf`\)](#), and [Host name definition file \(`imdd\_host\_name.conf`\)](#) in *Chapter 2. Definition Files*.

## Format

```
jddcreatetree -o directory-name [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdd\

In UNIX:

/opt/jplimm/bin/imdd/

## Arguments

### -o *directory-name*

Specifies the path of the directory that stores files to be created. The value can be an absolute path or a relative path from the directory where this command is executed. The value must be enclosed in double quotation marks (") if a space is included. The length of the path can be up to 200 characters.

### -h *logical-host-name*

Specifies the logical host name of JP1/IM if JP1/IM is running in a cluster system.

If this option is omitted, the command assumes the logical host name specified in the JP1\_HOSTNAME environment variable. If the JP1\_HOSTNAME environment variable is not specified, the command assumes the physical host name.

The length of *logical-host-name* must be equal to or less than 32 bytes to successfully collect the configuration information of the logical host. Otherwise, the `jddcreatetree` command fails with the message KAJY02015-E and the configuration management tree will not be updated.

## Notes

- You cannot execute the `jddcreatetree` command concurrently multiple times. Doing so results in an error.
- While the `jddupdatetree` command and `jddupdatesuggestion` command are running, you cannot execute the `jddcreatetree` command. Doing so results in an error.
- Before you can execute the `jddcreatetree` command, JP1/IM - Manager and the IM database must be running.
- To use `jddcreatetree` command with integrated manager hosts, the intelligent integrated management base service and the JP1/IM agent management base services of the base or relay manager hosts must be running.
- Do not stop JP1/IM - Manager or the IM database while the `jddcreatetree` command is running.
- If you have defined the base manager or the relay manager, verify if the system hierarchy has been synchronized, and then execute the `jddcreatetree` command on the integrated manager. When on site manager and relay manager, there is no need to execute the `jddcreatetree` command.
- Execute the `jddcreatetree` command during a period when no job is running on the JP1/AJS3 - Manager host. Otherwise, each processing might be delayed as both processing loads are required simultaneously.
- Execute the `jddcreatetree` command when the JP1/AJS3 - Manager service is running. If the `jddcreatetree` command is executed when the JP1/AJS3 - Manager service is stopped or in the process of starting or stopping, the information collection fails.
- Do not stop the JP1/AJS3 service from which information is collected when the `jddcreatetree` command is collecting information. Doing so might delay the stop processing of the service.
- The `jddcreatetree` command cannot collect the unit definition information that includes multi-byte characters other than Japanese. If such information is collected, the configuration management tree might not be displayed correctly.
- The information collection might fail if control characters are included in the information that the `jddcreatetree` command collects, such as unit names, unit definition information, execution agent names, and JP1 resource group names. Do not include control characters in the information to be collected.
- If JP1/PFM is a linked product for configuration collection, in the target host definition file for configuration collection (`imdd_target_host.conf`), set the definition so that JP1/PFM is first (at the top of the file), and then execute the `jddcreatetree` command.
- If the `jddcreatetree` command is executed according to a method different from the above, a failure might occur.

- If JP1/OA is a linked product for configuration collection, collect the configuration information for JP1/OA separately from collecting configuration for other products.
- If the `jddcreatetree` command is executed according to a method different from the following, a failure might occur.
  1. In the target host definition file for configuration collection (`imdd_target_host.conf`), set the definition for linked products other than JP1/OA.  
At this time, if JP1/PFM is to be included in the targets for configuration collection, set the definition so that JP1/PFM is first (at the top of the file).
  2. Execute the `jddcreatetree` command.
  3. In the target host definition file for configuration collection (`imdd_target_host.conf`), set the definition for JP1/OA.
  4. Use the `-o` option to specify the same directory name as in step 2, then execute the `jddcreatetree` command.

## Return values

|     |                                                                                          |
|-----|------------------------------------------------------------------------------------------|
| 0   | Normal termination                                                                       |
| 1   | Normal termination (invalid property)                                                    |
| 2   | Exclusive locked                                                                         |
| 3   | Invalid argument                                                                         |
| 4   | Invalid logical host name                                                                |
| 5   | Authentication information used by the Intelligent Integrated Management Base is not set |
| 6   | Missing information required for the <code>jddcreatetree</code> command to run           |
| 7   | No execution permission for the <code>jddcreatetree</code> command                       |
| 8   | The specified directory is not accessible                                                |
| 9   | The path to the specified directory is too long                                          |
| 11  | Failed to connect to the Intelligent Integrated Management Base                          |
| 12  | The Intelligent Integrated Management Base could not be authenticated                    |
| 13  | A required file does not exist                                                           |
| 14  | A required file could not be read                                                        |
| 15  | A required file has an invalid format                                                    |
| 16  | A required file has an invalid description                                               |
| 17  | Information could not be received from the plug-in                                       |
| 18  | Invalid information was received from the plug-in                                        |
| 20  | The IM management node file could not be created                                         |
| 21  | The IM management node link file could not be created                                    |
| 23  | The IM management node tree file could not be created                                    |
| 26  | The user used for authentication has insufficient permissions                            |
| 255 | System error                                                                             |

## Example 1

Specify that created files will be stored in C:\tmp:

```
$ jddcreatetree -o C:\tmp
KAJY02009-I The command (jddcreatetree) has started.
KAJY02010-I The command (jddcreatetree) terminates normally.
```

## Example 2

Specify that created files will be stored in C:\tmp and specify a logical host named ronri:

```
$ jddcreatetree -o C:\tmp -h ronri
KAJY02009-I The command (jddcreatetree) has started.
KAJY02010-I The command (jddcreatetree) terminates normally.
```

## Function

Based on the IM management node-related files acquired with the `jddcreatetree` command and the IM management node link definition file (`imdd_nodeLink_def.conf`) defined manually by the user, this command creates information regarding both the IM management node tree and the link between IM management nodes, and evaluates configuration information.

You can specify one of the following two options to designate how you want the system configuration information to be applied. The status of IM management nodes is evaluated differently depending on which option is specified.

If you specify the new and rebuilding mode as a way to apply system configuration information, this command acquires all the JP1 events stored in the integrated monitoring database and evaluates the status of each IM management node. If you specify the configuration change mode as a way to apply system configuration information, the command directly inherits and evaluates information regarding both existing JP1 events and mapping between those JP1 events and IM management nodes, instead of reacquiring all the JP1 events stored in the integrated monitoring database.

Specify the *new and rebuilding mode* in the following cases:

- When you create a new configuration
- When you correct any misconfiguration
- When you backed up the IM database (`jimdbbackup` command) and then recovered it (`jimdbrecover` command)
- When you unset up the integrated monitoring database (`jcodbunsetup` command) and set it up again (`jcodbsetup` command)
- When the intelligent integrated management database is backed up (execute `jimgndbbackup` command) and recovered (execute `jimgndbrestore` command)
- When you upgraded JP1/IM - Manager in the environment where the Intelligent Integrated Management Base was used

Specify the *configuration change mode* in the following case:

- When a managed target of the Intelligent Integrated Management Base is added, removed, or modified in addition to correction of misconfiguration

For details about how to apply system configuration information, see *3.5.7 Modes of applying system configuration information* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Before executing this command, execute the `jddsetaccessuser` command to set the user ID and password information required for authentication.

For details about the `jddcreatetree` command, see *jddcreatetree* in *Chapter 1. Commands*.

This command requests the Intelligent Integrated Management Base to apply the IM management node-related files and waits until the request is completed.

## Format

```
jddupdatetree -i directory-name [{-r|-c}] [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdd\

In UNIX:

/opt/jplimm/bin/imdd/

## Arguments

**-i** *directory-name*

Specifies the path of the directory that stores files created by the `jddcreatetree` command. The value can be an absolute path or a relative path from the directory where this command is executed. The value must be enclosed in double quotation marks (") if a space is included.

**-r|-c**

Specifies an option that determines how system configuration information will be applied.

**-r**

Specify this option when you want to apply system configuration information in the new and rebuilding mode. You cannot specify this option along with the **-c** option. In this mode, system configuration information is applied in almost the same manner as in version 12-10 or earlier.

**-c**

Specify this option when you want to apply system configuration information in configuration change mode. You cannot specify this option along with the **-r** option.

**-h** *logical-host-name*

Specifies the logical host name of JP1/IM if JP1/IM is running in a cluster system.

If this option is omitted, the command assumes the logical host name specified in the `JP1_HOSTNAME` environment variable. If the `JP1_HOSTNAME` environment variable is not specified, the command assumes the physical host name.

## Notes

- You cannot execute the `jddupdatetree` command concurrently multiple times. Doing so results in an error.
- While the `jddupdatetree` command and `jddupdatesuggestion` commands are running, you cannot execute the `jddcreatetree` command. Doing so results in an error.
- Before you can execute the `jddupdatetree` command, JP1/IM - Manager and the IM database must be running.
- Do not stop JP1/IM - Manager or the IM database while the `jddupdatetree` command is running.
- When neither the **-r** option nor the **-c** option is specified, system configuration information is applied according to the setting specified for the `jpl.imdd.simt.updateMode` property in the Intelligent Integrated Management Base definition file (`imdd.properties`).

When you newly install JP1/IM - Manager, `change` (configuration change mode) is set for this property. When you upgrade from version 12-10 or earlier, nothing is defined for this property. In this case, it is assumed that `reconfigure` (new and rebuilding mode) is set. We advise you to change this setting to suit your operational needs.

- If a registered JP1 event is included while the host mapping function for the problem source in the integrated monitoring DB is disabled, mapping between the JP1 event and the IM management node might fail, and the warning message KAJY02022-W might be output. For details regarding mapping between a JP1 event and an IM management node, see *3.9.1 Evaluations using JP1 events* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## Return values

|     |                                                                                          |
|-----|------------------------------------------------------------------------------------------|
| 0   | Normal termination                                                                       |
| 1   | Normal termination (invalid property)                                                    |
| 2   | Exclusive locked                                                                         |
| 3   | Invalid argument                                                                         |
| 4   | Invalid logical host name                                                                |
| 5   | Authentication information used by the Intelligent Integrated Management Base is not set |
| 6   | Missing information required for the <code>jddupdatetree</code> command to run           |
| 7   | No execution permission for the <code>jddupdatetree</code> command                       |
| 8   | The specified directory does not exist                                                   |
| 10  | IM database service is not running                                                       |
| 11  | Failed to connect to the Intelligent Integrated Management Base                          |
| 12  | The Intelligent Integrated Management Base could not be authenticated                    |
| 13  | A required file does not exist                                                           |
| 14  | A required file could not be read                                                        |
| 15  | A required file has an invalid format                                                    |
| 16  | A required file has an invalid description                                               |
| 17  | Event information could not be received                                                  |
| 19  | Information could not be received from the plug-in                                       |
| 22  | Master file alternate failed                                                             |
| 26  | The user used for authentication has insufficient permissions                            |
| 27  | There are suggestion definitions that are not mapped to any of the IM management nodes   |
| 28  | Failed to create suggestion-related master files <sup>#</sup>                            |
| 29  | Failed to replace the suggestion-related master files <sup>#</sup>                       |
| 255 | System error                                                                             |

#

These files collectively refer to master information related to suggestions (including the suggestion definition master file, etc.). They are loaded when the JP1/IM - Manager service starts.

## Example 1

Specify that files created by the `jddcreatetree` command are stored in `C:\tmp`:

```
$ jddupdatetree -i C:\tmp
KAJY02009-I The command (jddupdatetree) has started.
KAJY02010-I The command (jddupdatetree) terminates normally.
```

## Example 2

Specify that files created by the `jddcreatetree` command are stored in `C:\tmp` and specify a logical host named `ronri`:

```
$ jddupdatetree -i C:\tmp -h ronri
KAJY02009-I The command (jddupdatetree) has started.
KAJY02010-I The command (jddupdatetree) terminates normally.
```

## Example 3

Execute the command with the new and rebuilding mode specified as a way to apply system configuration information:

```
$ jddupdatetree -i C:\tmp -r
KAJY02009-I The command (jddcreatetree) has started.
KAJY02010-I The command (jddcreatetree) terminate normally.
```

## Example 4

Execute the command with the configuration change mode specified as a way to apply system configuration information:

```
$ jddupdatetree -i C:\tmp -c
KAJY02009-I The command (jddcreatetree) has started.
KAJY02010-I The command (jddcreatetree) terminates normally.
```

## Function

This command executes definitions related to the authentication of the Intelligent Integrated Management Base. The user ID and password defined with this command are used for authentication under the following circumstances:

- When connecting to a monitored JP1 product from the Intelligent Integrated Management Base
- When connecting to the Intelligent Integrated Management Base by using one of the commands provided by the Intelligent Integrated Management Base
- Authentication of the Intelligent Integrated Management Base when OpenID authentication linkage is enabled

## Format

```
jddsetaccessuser -id user-ID -pw password [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdd\

In UNIX:

/opt/jp1imm/bin/imdd/

## Arguments

**-id** *user-ID*

Specifies a user ID of user who has administrator permissions for JP1/IM, JP1/PFM, and JP1/AJS.

The user ID must be a character string of 1 to 31 bytes.

Acceptable characters are alphanumeric characters and the following symbols: exclamation mark (!), dollar sign (\$), percent sign (%), ampersand (&), underscore (\_), hyphen (-), hash mark (#), and at mark (@).

Specified uppercase characters are handled as lowercase.

**-pw** *password*

Specifies a password for the user who you specified with the **-id** option.

The password must be a character string of 6 to 32 bytes.

Acceptable characters are alphanumeric characters and the following symbols: exclamation mark (!), hash mark (#), dollar sign (\$), percent sign (%), ampersand (&), underscore (\_), hyphen (-), asterisk (\*), forward slash (/), single quotation mark ( ' ), caret (^), left square bracket ( [ ), right square bracket ( ] ), left curly bracket ( { ), right curly bracket ( } ), left parenthesis ( ( ), right parenthesis ( ) ), semicolon ( ; ), vertical bar ( | ), equal sign (=), plus sign (+), question mark (?), left angle bracket (<), and right angle bracket (>).

A password is case sensitive. A password must be enclosed in double quotation marks (") if any of the following symbols is included: caret (^), left angle bracket (<), right angle bracket (>), vertical bar (|), and ampersand (&).

-h *logical-host-name*

Specifies the logical host name if you operate JP1/IM in a cluster system. If this option is omitted, the command assumes the logical host name specified in the JP1\_HOSTNAME environment variable. If the JP1\_HOSTNAME environment variable is not specified, the command assumes the physical host name.

## Return values

|     |                                                          |
|-----|----------------------------------------------------------|
| 0   | Normal termination                                       |
| 1   | Invalid argument                                         |
| 2   | A specified argument value was invalid                   |
| 3   | The file could not be created                            |
| 4   | Invalid logical host name                                |
| 7   | No execution permission for the jddsetaccessuser command |
| 255 | System error                                             |

## Example 1

Specify a password of ABCDEF for the user UserA:

```
$ jddsetaccessuser -id UserA -pw ABCDEF
KAJY02009-I The command (jddsetaccessuser) has started.
KAJY02010-I The command (jddsetaccessuser) terminates normally.
```

## Example 2

Specify a password of ABCDEF for the user UserA on the logical host ronri:

```
$ jddsetaccessuser -id UserA -pw ABCDEF -h ronri
KAJY02009-I The command (jddsetaccessuser) has started.
KAJY02010-I The command (jddsetaccessuser) terminates normally.
```

# jddsetproxyuser

---

## Function

This command sets authentication information for the proxy server when REST APIs are executed from plug-ins that are provided by JP1/IM - Manager (Intelligent Integrated Management Base). This setting is not needed if you do not use proxy server authentication.

## Format 1

```
Usage:
jddsetproxyuser {-list|-add -id user-ID -pw password |-rm -id user-ID} [-h logical-host-name]
```

## Format 2

```
jddsetproxyuser -list [-h logical-host-name]
```

## Format 3

```
jddsetproxyuser -add -id user-ID -pw password [-h logical-host-name]
```

## Format 4

```
jddsetproxyuser -rm -id user-ID [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdd\

In UNIX:

/opt/jplimm/bin/imdd/

## Arguments

-list

Specify this option if you get authentication information for the proxy server configured in the Intelligent Integrated Management Base.

-add

Specify this option if you update the authentication information for the proxy server configured in the Intelligent Integrated Management Base. If this option is specified, the -id option and -pw option must be specified. If they are omitted, an error occurs.

- rm**  
Specify this option if you remove the authentication information for the proxy server configured in the Intelligent Integrated Management Base. If this option is specified, the **-id** option must be specified. If it is omitted, an error occurs.
- id *user-ID***  
Specifies the user ID of a user for proxy server authentication.
- pw *password***  
Specifies the password for the user you specified with the **-id** option.
- h *logical-host-name***  
Specifies the logical host name of JP1/IM if JP1/IM is running in a cluster system.  
If this option is omitted, the command assumes the logical host name specified in the `JP1_HOSTNAME` environment variable. If the `JP1_HOSTNAME` environment variable is not specified, the command assumes the physical host name.

## Notes

- You cannot execute the `jddsetproxyuser` command concurrently multiple times. Doing so results in an error.
- Do not stop JP1/IM - Manager or the IM database while the `jddsetproxyuser` command is running.
- You cannot execute the `jddsetproxyuser` command together with the API for setting proxy authentication information. For details about the proxy credential setup API, see [5.9.1 Proxy credential setup](#).
- If the `jddsetproxyuser` command is executed while JP1/IM - Manager is not running, the `KAJY52015-W` message is output and the setting will take effect next time JP1/IM - Manager is started.

## Return values

|     |                                                                                          |
|-----|------------------------------------------------------------------------------------------|
| 0   | Normal termination                                                                       |
| 1   | Invalid argument                                                                         |
| 2   | Exclusive locked                                                                         |
| 3   | A specified argument value was invalid                                                   |
| 4   | Invalid logical host name                                                                |
| 5   | Authentication information used by the Intelligent Integrated Management Base is not set |
| 7   | No execution permission for the <code>jddsetproxyuser</code> command                     |
| 11  | Failed to connect to the Intelligent Integrated Management Base                          |
| 12  | The Intelligent Integrated Management Base could not be authenticated                    |
| 13  | Update of proxy authentication information failed                                        |
| 255 | System error                                                                             |

## Example 1

The following is an example of getting authentication information for the proxy server configured in the Intelligent Integrated Management Base:

```
jddsetproxyuser -list
KAJY02009-I The command (jddsetproxyuser) has started.
User1
```

```
User2
KAJY02010-I The command (jddsetproxyuser) terminates normally.
```

## Example 2

The following is an example of updating authentication information for the proxy server configured in the Intelligent Integrated Management Base:

```
jddsetproxyuser -add -id User3 -pw PASSWORD
KAJY02009-I The command (jddsetproxyuser) has started.
KAJY02010-I The command (jddsetproxyuser) terminates normally.

jddsetproxyuser -list
KAJY02009-I The command (jddsetproxyuser) has started.
User1
User2
User3
KAJY02010-I The command (jddsetproxyuser) terminates normally.
```

## Example 3

The following is an example of removing authentication information for the proxy server configured in the Intelligent Integrated Management Base:

```
jddsetproxyuser -rm -id User3
KAJY02009-I The command (jddsetproxyuser) has started.
KAJY02010-I The command (jddsetproxyuser) terminates normally.

jddsetproxyuser -list
KAJY02009-I The command (jddsetproxyuser) has started.
User1
User2
KAJY02010-I The command (jddsetproxyuser) terminates normally.
```

# jddupdatesuggestion

---

## Function

This command loads all suggestion definition files located under the specified directory and applies them to the Intelligent Integrated Management Base.

When the suggestion definition files have already been applied to the Intelligent Integrated Management Base, the command discards all the definitions that have been applied and replaces them with the definitions provided in the specified suggestion definition files. When there is a mistake in one of the definitions provided in the suggestion definition files, the command suspends its processing the moment the mistake is found.

Before executing this command, execute the `jddsetaccessuser` command to set the user ID and password necessary for authentication.

## Format

```
jddupdatesuggestion -i directory-name [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdd\

In UNIX:

/opt/jplimm/bin/imdd/

## Arguments

`-i directory-name`

Specify either the absolute path to the directory under which the suggestion definition files are saved or the relative path to the same directory from the location where this command is executed. If the path name contains a space, enclose the entire path name in double quotation marks (").

`-h logical-host-name`

Specify the logical host name when JP1/IM is running in a cluster system. When you omit this option, the command assumes that the logical host name specified in the `JP1_HOSTNAME` environment variable is set. When the `JP1_HOSTNAME` environment variable is not specified, the command assumes that the physical host name is set.

## Notes

- You cannot execute multiple `jddupdatesuggestion` commands at a time. Doing so results in an error.
- You cannot execute this command while the `jddcreatetree` command or the `jddupdatetree` command is being executed. Doing so results in an error.

- You have to execute the `jddupdatesuggestion` command while the JP1/IM - Manager service is up and running.

## Return values

|     |                                                                                          |
|-----|------------------------------------------------------------------------------------------|
| 0   | Normal termination                                                                       |
| 1   | Normal termination (with a warning message)                                              |
| 2   | Concurrent execution error                                                               |
| 3   | Invalid argument                                                                         |
| 4   | Invalid logical host name                                                                |
| 5   | Authentication information used by the Intelligent Integrated Management Base is not set |
| 6   | No execution permission for the <code>jddupdatesuggestion</code> command assigned        |
| 7   | The specified directory does not exist                                                   |
| 8   | Failed to connect to the Intelligent Integrated Management Base                          |
| 9   | The Intelligent Integrated Management Base could not be authenticated                    |
| 10  | The user used for authentication has insufficient permissions                            |
| 11  | The suggestion definition files do not exist                                             |
| 12  | Failed to load the suggestion definition files                                           |
| 13  | The suggestion definition files have an invalid format                                   |
| 14  | The suggestion definition files have an invalid description                              |
| 15  | Failed to create a suggestion definition master file <sup>#</sup>                        |
| 255 | System error                                                                             |

#

This refers to a single file to which information contained in the suggestion definition files specified with the `-i` option is output. This file serves as master information.

## Example 1

Specify `C:\tmp` as the location to which to store the suggestion definition files:

```
$ jddupdatesuggestion -i C:\tmp
KAJY02009-I The command (jddupdatesuggestion) has started.
KAJY02010-I The command (jddupdatesuggestion) terminates normally.
```

## Example 2

Specify `C:\tmp` as the location to which to store the suggestion definition files and `ronri` as the logical host:

```
$ jddupdatesuggestion -i C:\tmp -h ronri
KAJY02009-I The command (jddupdatesuggestion) has started.
KAJY02010-I The command (jddupdatesuggestion) terminates normally.
```

# jddsetopinfo

---

## Function

This command takes the Intelligent Integrated Management Base client information (client IDs and client secrets) registered with the OpenID provider for OpenID authentication linkage, and sets it in JP1/IM - Manager (Intelligent Integrated Management Base).

The client IDs and client secrets are used to authenticate the Intelligent Integrated Management Base clients registered with the OpenID provider. In order for this to work, this command must be executed prior to starting JP1/IM - Manager (Intelligent Integrated Management Base).

## Format 1

```
Usage:
jddsetopinfo {-list|-add -provider OpenID-provider-name -id client-ID -secret client-secret|-rm -provider OpenID-provider-name} [-h logical-host-name]
```

## Format 2

```
jddsetopinfo -list [-h logical-host-name]
```

## Format 3

```
jddsetopinfo -add -provider OpenID-provider-name -id client-ID -secret client-secret [-h logical-host-name]
```

## Format 4

```
jddsetopinfo -rm -provider OpenID-provider-name [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdd\

In UNIX:

/opt/jplimm/bin/imdd/

## Arguments

-list

Specify this option to collect the client information registered with OpenID providers that is set in the Intelligent Integrated Management Base.

The only option you can specify along with this option is the `-h` option.

`-add`

Specify this option to add the client information registered with OpenID providers to the Intelligent Integrated Management Base or update such client information that is set in the Intelligent Integrated Management Base. If you specify this option, the specification of the `-provider`, `-id`, and `-secret` options is mandatory. Without these options specified, the error message KAJY02011-E is output. This option cannot be specified along with any other options.

`-rm`

Specify this option to delete the client information registered with OpenID providers from the Intelligent Integrated Management Base. If you specify this option, the specification of the `-provider` option is mandatory. Without this option specified, the error message KAJY02011-E is output.

This option cannot be specified along with options other than the `-provider` and `-h` options.

`-provider` *OpenID-provider*

Specify the OpenID provider name. The value you specify here must be the *<key-name-of-the-OpenID-provider>* that you have set as an OpenID provider definition inside the Intelligent Integrated Management Base definition file (`imdd.properties`). For details, see *Intelligent Integrated Management Base definition file (imdd.properties)* in *Chapter 2. Definition Files*.

This option cannot be specified along with the `-list` option.

`-id` *client-ID*

Specify the client ID. The characters you specify here must conform to the specifications set out by the applicable OpenID provider.

This option cannot be specified along with options other than the `-list` and `-rm` options.

`-secret` *client-secret*

Specify the client secret for the client ID specified with the `-id` option. The characters you specify here must conform to the specifications set out by the applicable OpenID provider.

This option cannot be specified along with options other than the `-list` and `-rm` options.

`-h` *logical-host-name*

Specify the logical host name when JP1/IM is running in a cluster system. When you omit this option, the command assumes that the logical host name specified in the `JP1_HOSTNAME` environment variable is set. When the `JP1_HOSTNAME` environment variable is not specified, the command assumes that the physical host name is set.

## Notes

- You cannot execute multiple `jddsetopinfo` commands at a time. Doing so results in an error.
- You have to execute the `jddsetopinfo` command before starting JP1/IM - Manager (Intelligent Integrated Management Base).
- If you execute the `jddsetopinfo` command while JP1/IM - Manager (Intelligent Integrated Management Base) is up and running, the settings are applied the next time you start JP1/IM - Manager (Intelligent Integrated Management Base).

## Return values

|   |                                       |
|---|---------------------------------------|
| 0 | Normal termination                    |
| 2 | Failed to establish exclusive control |
| 3 | Invalid argument                      |

|     |                                                                   |
|-----|-------------------------------------------------------------------|
| 4   | Invalid logical host name                                         |
| 5   | Failed to specify the setting                                     |
| 6   | The specified OpenID provider's client information does not exist |
| 7   | No execution permission for the <code>jddsetopinfo</code> command |
| 255 | System error                                                      |

## Example 1

Collect the client information registered with OpenID providers that is set in the Intelligent Integrated Management Base:

```
jddsetopinfo -list
KAJY02009-I The command (jddsetopinfo) has started.
okta:IM1210
keycloak:IM1210
KAJY02010-I The command (jddsetopinfo) terminates normally.
```

## Example 2

Add the client information registered with the OpenID provider to the Intelligent Integrated Management Base or update such information that is set in the Intelligent Integrated Management Base:

```
jddsetopinfo -add -provider okta -id id001 -secret SECRET
KAJY02009-I The command (jddsetopinfo) has started.
KAJY02010-I The command (jddsetopinfo) terminates normally.
```

Check the current status.

```
jddsetopinfo -list
KAJY02009-I The command (jddsetopinfo) has started.
okta:id001
keycloak:id001
KAJY02010-I The command (jddsetopinfo) terminates normally.
```

## Example 3

Delete the client information registered with the OpenID provider from the Intelligent Integrated Management Base:

```
jddsetopinfo -rm -provider okta
KAJY02009-I The command (jddsetopinfo) has started.
KAJY02010-I The command (jddsetopinfo) terminates normally.
```

Check the current status.

```
jddsetopinfo -list
KAJY02009-I The command (jddsetopinfo) has started.
keycloak:User2
KAJY02010-I The command (jddsetopinfo) terminates normally.
```

# jddupdatessomap

## Function

This command applies the mapping information defined in the single sign-on mapping definition file to JP1/IM - Manager (Intelligent Integrated Management Base).

Note that if this command is executed when the single sign-on mapping definition file has no valid property at all, the KAJY52031-W message is output and the applied single sign-on mapping definitions are cleared.

## Format

```
Usage:
jddupdatessomap [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command is executed from the administrator console.)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdd\

In UNIX:

/opt/jp1imm/bin/imdd/

## Arguments

-h *logical-host-name*

Specify the logical host name when JP1/IM is running in a cluster system. When you omit this option, the command assumes that the logical host name specified in the JP1\_HOSTNAME environment variable is set. When the JP1\_HOSTNAME environment variable is not specified, the command assumes that the physical host name is set.

## Notes

- You cannot execute multiple jddupdatessomap commands at a time. Doing so results in an error.
- You have to execute the jddupdatessomap command while the Intelligent Integrated Management Base service is up and running.

## Return values

|   |                                                                                  |
|---|----------------------------------------------------------------------------------|
| 0 | Normal termination                                                               |
| 1 | Normal termination (invalid property or empty single sign-on mapping definition) |
| 2 | Failed to establish exclusive control                                            |
| 3 | Invalid argument                                                                 |
| 4 | Invalid logical host name                                                        |

|     |                                                                                           |
|-----|-------------------------------------------------------------------------------------------|
| 5   | Authentication information used by the Intelligent Integrated Management Based is not set |
| 7   | No permission necessary to execute the command                                            |
| 11  | Failed to connect to the Intelligent Integrated Management Base                           |
| 12  | The Intelligent Integrated Management Base could not be authenticated                     |
| 13  | Failed to apply information to the Intelligent Integrated Management Base                 |
| 14  | Definition file load error                                                                |
| 255 | System error                                                                              |

## Example

```
jddsetssomap
KAJY02009-I The command (jddsetssomap) has started.
KAJY02010-I The command (jddsetssomap) terminates normally.
```

# jddupdateaction

## Function

This command loads a user-defined auto response action definition file and applies it to Intelligent Integrated Management Base.

## Format

```
Usage:
jddupdateaction [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdd\

In UNIX:

/opt/jplimm/bin/imdd/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host that executes the command. If this option is omitted, the command assumes the logical host name specified in the JP1\_HOSTNAME environment variable. If the JP1\_HOSTNAME environment variable is set empty string, the command assumes the physical host name,

If this option is omitted and the JP1\_HOSTNAME environment variable is not specified, the command assumes the physical host name.

## Notes

- If you use this command, JP1/IM3-Manager service must be running.

## Return values

|   |                                                                                        |
|---|----------------------------------------------------------------------------------------|
| 0 | Normal termination                                                                     |
| 1 | Normal termination (with a warning message)                                            |
| 2 | Invalid option                                                                         |
| 3 | Invalid logical host name                                                              |
| 4 | Authentication data used by Intelligent Integrated Management Base has not been setup. |
| 5 | No execution permission for the command                                                |
| 6 | Failed to connect to the Intelligent Integrated Management Base                        |

|     |                                                                          |
|-----|--------------------------------------------------------------------------|
| 7   | Failed to be authenticated to the Intelligent Integrated Management Base |
| 8   | The user used for authentication has insufficient permissions            |
| 9   | Failed to load the auto response action definition file                  |
| 10  | Incorrect format of the auto response action definition file             |
| 11  | Incorrect content of the auto response action definition file            |
| 255 | System error occurred                                                    |

## Example

The following shows an example in which the logical host is set to "ronri".

```
$ jddupdateaction -h ronri
KAJY02009-I The command (jddupdateaction) has started.
KAJY02010-I The command (jddupdateaction) terminates normally.
```

## jcfview (Windows only)

---

### Function

This command starts IM Configuration Management - View. If the `-h`, `-u`, and `-p` options are specified, the command logs in to IM Configuration Management - View automatically without displaying the Login window.

### Format

```
jcfview [-h connection-target-host-name] [-u user-name] [-p password]
```

### Execution permission

None

### Storage directory

*View-path*\bin\

### Arguments

`-h connection-target-host-name`

Specifies the name of the host where the IM Configuration Management to be logged into is running. For the host name, from 1 to 255 bytes of characters are permitted. You can specify only a host where JP1/IM - Manager is running.

For the connection-target host name, you can specify the following:

- Host name defined on the host where the command is used
- Host name whose address can be resolved on the host where the command is used
- IP address

Only addresses in IPv4 address format can be specified as IP address. Addresses in IPv6 address format cannot be specified.

This option is optional. However, if you specify the `-p` option, you must specify this option.

If you start IM Configuration Management - View by specifying only the `-h` option or both the `-h` and the `-u` options, the Login window is displayed by using these arguments as the default values. If only the `-h` and `-p` options are specified to start IM Configuration Management - View, an error results.

`-u user-name`

Specifies a JP1 user name that has been registered in the authentication server. For the JP1 user name, from 1 to 31 alphanumeric characters are permitted (for alphabetic characters, only lowercase letters are permitted).

This option is optional. However, if you specify the `-p` option, you must specify this option.

If you start IM Configuration Management - View by specifying only the `-u` option or both the `-h` and the `-u` options, the Login window is displayed by using these arguments as the default values. If only the `-u` and `-p` options are specified to start IM Configuration Management - View, an error results.

`-p password`

Specifies the password for the specified user name. For the password, from 6 to 32 alphanumeric characters are permitted. Alphabetic characters are case sensitive. This option is optional.

If you specify this option, you must also specify the `-h` and `-u` options.

## Return values

|     |                                                          |
|-----|----------------------------------------------------------|
| 0   | Normal termination                                       |
| 1   | Argument error                                           |
| 2   | Insufficient memory                                      |
| 3   | Resource acquisition failed                              |
| 4   | Error message creation failed                            |
| 5   | Forced termination of IM Configuration Management - View |
| 255 | System error                                             |

## Example 1

Start IM Configuration Management - View and display the Login window:

```
jcfview
```

## Example 2

Enable automatic login without displaying the Login window:

This example specifies the connection-target host (`host1`), user name (`user2`), and password (`password`) to start IM Configuration Management - View:

```
jcfview -h host1 -u user2 -p password
```

# jcfvirtualchstat

---

## Function

Updates the virtualization configuration of the specified host.

If the virtualization configuration managed by the virtualization environment management software is changed, the change can be applied to IM Configuration Management by executing this command.

Note that a maximum of five commands can be executed concurrently.

## Format

```
jcfvirtualchstat      -c host-name
                      [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imcf\

In UNIX:

/opt/jplimm/bin/imcf/

## Arguments

-c *host-name*

Specifies the name of the host whose virtualization configuration information is to be collected. For the host name, specify a maximum of 255 characters.

-h *logical-host-name*

For operation in a cluster system, this option specifies the logical host name. Specify the name of a logical host with a maximum of 255 bytes. If this option is omitted, the logical host name specified for the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.

If you execute with standby host in UNIX / Linux, an unwanted directory named */shared-directory-name* is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- */shared-directory-name/jplimm*

- `/shared-directory-name/jplimm/log`
- `/shared-directory-name/jplimm/log/imcf`

Delete these unwanted directory and files, they will never to be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|                |                                                         |
|----------------|---------------------------------------------------------|
| 0              | Normal termination                                      |
| 4              | Invalid option                                          |
| 8              | Unable to connect to the server                         |
| 12             | Insufficient memory                                     |
| 16             | Invalid permission                                      |
| 21             | Upper limit for number of concurrent executions reached |
| 24             | Input/output error                                      |
| 120            | System error occurred                                   |
| 124            | Termination due to an error not listed here             |
| 201 or greater | JavaVM start error occurred                             |

## jco\_killall.cluster (UNIX only)

---

### Function

When you are operating in a cluster system, this command forcibly terminates the JP1/IM - Manager processes.

Executing the `jco_stop.cluster` command during cluster operation may not stop all processes, resulting in a cluster operation failure. The `jco_killall.cluster` command forcibly terminates processes. Use this command only when processes cannot be terminated by the normal method of stopping JP1/IM - Manager Service.

The command can terminate the following processes:

- Process management (`jco_spm`)
- Automatic Action Service (`jcmain`)
- Event Console Service (`evtcon`)
- Event Base Service (`evflow`)
- Event Generation Service (`evgen`)
- Central Scope Service (`jcsmain`)
- IM Configuration Management Service (`jcfmain`)
- IM database service
- Intelligent Integrated Management database service
- Trend Data Management Service
- Intelligent Integrated Management Base Service (`jddmain`)
- Servicing JP1/IM agent management base (`imbase`)
- Servicing JP1/IM agent management base (`imbaseproxy`)

### Format

```
jco_killall.cluster [logical-host-name]
```

### Execution permission

Superuser permissions

### Storage directory

`/etc/opt/jp1cons/`

### Arguments

*logical-host-name*

Specifies a logical host name set in JP1/Base. You can specify 1 to 32 bytes of characters. If this option is omitted, the command assumes the logical host name specified in the `JP1_HOSTNAME` environment variable. If the `JP1_HOSTNAME` environment variable is not specified, the command assumes the physical host name.

## Notes

This command checks the first 32 bytes of the logical host name, and then forcibly terminates the corresponding process. The command cannot forcibly terminate a process on a logical host whose name consists of 33 bytes or more.

## Return values

|   |                                    |
|---|------------------------------------|
| 0 | Normal termination                 |
| 1 | Logical host name is not specified |
| 2 | There is no log directory          |

## Function

This command updates the status of JP1/IM - Manager processes. When you have changed the definition information for JP1/IM - Manager, you must reload the new information to enable it.

The `jco_spmd_reload` command enables the information in the definition files listed below. For details, see *When the definitions are applied* for each definition file in [Chapter 2. Definition Files](#).

- The following information is located in the automated action environment definition file (`action.conf.update`):
  - AND event storage period (`EVENTALLIVEPERIOD`)
  - Default action executing user (`ACTIONEXECUSER`)
  - Automatic action issuance event (`SENDABLE_EVENT`)
  - Event-issuing host name acquisition method (`HOSTINEVENT`)
- Automatic action notification definition file (`actnotice.conf`)
- Extended startup process definition file (`jplco_service.conf`)
- Health check definition file (`jcohc.conf`)
- Event guide information file (`jco_guide.txt`)
- Host information file (`jcs_hosts`)
- Guide information file (`jcs_guide_xxx.txt`)
- Correlation event generation system profile (`egs_system.conf`)
- Correlation event generation environment definition file
- Definition file for manually registering incidents (`incident.conf`)
- Configuration file for incident inheritance information (`incident_info.conf`)
- File that defines the event source host mapping (`user_hostmap.conf`)
- Severity changing definition file (`jcochsev.conf`)
- File that defines which items are displayed for severity changing definitions (`chsev_attr_list.conf`)
- File that defines automatic input of severity changing definitions (`chsev_auto_list.conf`)
- File that defines which items are displayed for event conditions (`attr_list.conf`)
- File that defines which items are displayed for repeated event conditions (`event_storm_attr_list.conf`)
- File that defines automatic input of repeated event conditions (`event_storm_auto_list.conf`)
- File that defines which items are displayed for common exclusion-conditions (`common_exclude_filter_attr_list.conf`)
- File that defines automatic input of common exclusion-conditions (`common_exclude_filter_auto_list.conf`)
- Definition file for extended event attributes
- Definition file for extended event attributes (extended file)
- Definition file for changed display messages (`jcochmsg.conf`)

- File that defines automatic input of display message change definitions (`chmsg_auto_list.conf`)
- File that defines which items are displayed for display message change definitions (`chmsg_attr_list.conf`)
- Definition file for opening monitor windows
- Apply-IM-configuration-method definition file (`jplcf_applyconfig.conf`)

## Format

```
jco_spmc_reload [-h logical-host-name]  
                [-t monitoring-period]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jplcons/bin/

## Arguments

`-h logical-host-name`

When you are operating in a cluster system, this option specifies the logical host name. The permitted length is from 1 to 255 bytes characters. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

`-t monitoring-period`

Specifies in seconds the amount of time to wait for the `jco_spmc_reload` command to terminate. The permitted value is from 0 to 32,767 (seconds). If the `jco_spmc_reload` command does not terminate within the specified amount of time, the system assumes that execution of the `jco_spmc_reload` command has failed. The default is 60 seconds.

## Notes

- The `jco_spmc_reload` command cannot be executed together with the `jco_spmc_status` command.

## Return values

|              |                      |
|--------------|----------------------|
| 0            | Normal termination   |
| Other than 0 | Abnormal termination |

# jco\_spmd\_status

## Function

This command displays the startup status of the JP1/IM - Manager processes.

## Format

```
jco_spmd_status [-h logical-host-name]  
                [-t monitoring-period]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jplcons/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. The permitted length is from 1 to 255 bytes characters. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-t *monitoring-period*

Specifies in seconds the amount of time to wait for the jco\_spmd\_status command to terminate. The permitted value is from 0 to 32,767 (seconds). If the jco\_spmd\_status command does not terminate within the specified amount time, the system assumes that execution of the jco\_spmd\_status command has failed. The default is 60 seconds.

## Return values

|    |                                                                                                                                                                                                                                                                                       |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | All child processes are running                                                                                                                                                                                                                                                       |
| 1  | <ul style="list-style-type: none"><li>• Error occurred during communication, such as in process management.</li><li>• When you are operating in a cluster system, the shared folder (shared directory) is not mounted.</li><li>• Execution permission error (Windows only).</li></ul> |
| 4  | Some child processes are running                                                                                                                                                                                                                                                      |
| 8  | All stopped                                                                                                                                                                                                                                                                           |
| 12 | Request processing is underway (can be retried)                                                                                                                                                                                                                                       |

## jco\_start (UNIX only)

---

### Function

This command is a script for starting JP1/IM - Manager automatically.

To execute this command, you must have performed the following procedure after you completed installation and setup of JP1/IM - Manager:

```
# cd /etc/opt/jplcons
# cp -p jco_start.model jco_start
```

With these operations, JP1/IM - Manager starts automatically when the system starts. If you do not want JP1/IM - Manager to start automatically at the system startup, do not perform these operations.

You must perform these operations if you set JP1/IM - Manager version 10 or earlier to start automatically.

For details about configuring the automatic startup settings, see *2.18.2 Setting automatic startup and automatic stop (for UNIX)* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

To start JP1/IM - Manager manually, execute the `/etc/opt/jplcons/jco_start.model` script, or a file to which this script has been copied.

If you use a script to which `jco_start.model` has been copied in JP1/IM - Manager version 10 or earlier, overwrite it with `jco_start.model`.

Before you execute this command, make sure that JP1/Base is running. JP1/IM - Manager uses the functions of JP1/Base (prerequisite product). If this command is executed when the following all conditions are satisfied, the command starts the IM database service and then starts JP1/IM - Manager:

- The IM database service has been set up.
- The integrated monitoring database is used or IM Configuration Management Service is set to be started.

If you are using Intelligent Integrated Management Database, after starting IM Database services the above, further services start in the order of the Intelligent Integrated Management Database and Trend Data Management Service, and then start JP1/IM - Manager at the end.

The command terminates with a return value of 0 after issuing a startup request to the group of JP1/IM - Manager processes. To check whether the group of processes has started successfully, use the `jco_spmc_status` command after the `jco_start` command has terminated to display the process IDs of the services that have started. Note that the process ID of the IM database service is not displayed.

### Format

jco\_start

### Execution permission

Superuser permissions

### Storage directory

`/etc/opt/jplcons/`

## Note

- If you want to execute this command as a remote shell command, disconnect standard input, standard output, and standard error output (assign `/dev/null` to standard input, standard output, and standard error output). Note that the remote shell command might not terminate even when processing for starting JP1/IM - Manager has finished.
- Execute this command in an environment in which the environment variable `JP1_HOSTNAME` has not been set. If you execute this command in an environment in which the environment variable `JP1_HOSTNAME` has been set, the command will attempt to start JP1/IM - Manager on the logical host set in the environment variable `JP1_HOSTNAME` rather than on the physical host. Because this command does not support logical hosts, you must delete the environment variable `JP1_HOSTNAME` if you want to start JP1/IM - Manager on the physical host.
- The `jco_start` command cannot be executed together with the `jco_spmc_status` command.

## Return values

|   |                                                                                                                     |
|---|---------------------------------------------------------------------------------------------------------------------|
| 0 | Normal termination                                                                                                  |
| 1 | More than one argument is specified, the event service is not running, or the IM database service cannot be started |
| 2 | There is no log directory                                                                                           |

## Example 1

When the integrated monitoring database is used:

Input value:

```
jco_start
```

Result:

```
Please wait a minutes, now starting the IM database service...
KNAN11188-I The status of the IM database service will now be confirmed.
KNAN11183-I The IM database service is stopped.
KNAN11189-I The status of the IM database service was successfully confirmed.
Please wait a minutes, now starting JP1/IM - Manager...
KAVB3690-I Processing to report the status of JP1_CONS has started.
Display the running processes
process name  process ID
      evflow      18990
      jcamain      19036
      evtcon       19037
KAVB3691-I All the processes have started.
```

## Example 2

When the integrated monitoring database is not used and IM Configuration Management Service has not started:

Input value:

```
jco_start
```

Result:

```
Please wait a minutes, now starting JP1/IM - Manager...
KAVB3690-I Processing to report the status of JP1_CONS has started.
```

```
Display the running processes
process name  process ID
      evflow      19237
      jcamain      19277
      evtcon       19278
KAVB3691-I All the processes have started.
```

### Example 3

When the IM database is not used:

Input value:

```
jco_start
```

Result:

```
Please wait a minutes, now starting the IM database service...
KNAN11188-I The status of the IM database service will now be confirmed.
KNAN11109-E The IM database service is not set up.
Unable start JP1/IM - Manager.
```

### Example 4

When the integrated monitoring database and the trend data management database are used:

Input value:

```
jco_start
```

Result:

```
Please wait a minutes, now starting the IM database service...
KNAN11188-I The status of the IM database service will now be confirmed.
KNAN11183-I The IM database service is stopped.
KNAN11189-I The status of the IM database service was successfully confirmed.
Please wait a minutes, now starting the Intelligent Integrated DB...
KNAN12055-I The Intelligent Integrated Management Database Service will now start.
KNAN12057-I The trend data management service will now start.
KNAN12056-I The Intelligent Integrated Management Database Service started normally.
KNAN12058-I The trend data management service started normally.
KNAN12044-I The processing to confirm the service operating status will now start.
KNAN12047-I The Intelligent Integrated Management Database Service is running.
KNAN12048-I The trend data management service is running.
KNAN12045-I The processing to confirm the service operating status ended normally.
Please wait a minutes, now starting JP1/IM - Manager...
KAVB3690-I Processing to report the status of JP1_CONS has started.
Display the running processes
process name  process ID
      evflow      26290
```

```
    jcamain      26374
    evtcon       26375
    jddmain      26291
KAVB3691-I All the processes have started.
```

# jco\_start.cluster (UNIX only)

---

## Function

When you are operating in a cluster system, this command starts JP1/IM - Manager on the logical host.

If you register this command into the cluster software, JP1/IM - Manager starts.

Before you execute this command, start JP1/Base on the same logical host. An error results if this command is executed while the event service of JP1/Base is not running.

The command terminates with a return value of 0 after issuing a startup request to the group of JP1/IM - Manager processes. To check whether the group of processes has started successfully, use the `jco_spmc_status` command after the `jco_start.cluster` command has terminated.

If this command is executed when the following condition is satisfied, the command starts the IM database service, starts in the order of the intelligent integrated management database and the trend data management service, and then starts JP1/IM - Manager:

- IM database service startup conditions (all conditions must be met)
  - You have set up IM database on your logical host.
  - The integrated monitoring database on the logical host is enabled or IM Configuration Management Service is set to be started.
- Startup requirements for the intelligent integrated management database service and the trend data management service
  - You have set up the intelligent integrated management database on the logical host.

To execute this command, you must have executed `jp1cc_setup_cluster` and `jp1cs_setup_cluster` after installing and setting up JP1/IM - Manager. For the IM database service, you must set up the cluster system for the IM database service. For details about setting up a cluster system, see *Chapter 8. Operation and Environment Configuration in a Cluster System (for UNIX)* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

## Format

```
jco_start.cluster [logical-host-name]
```

## Execution permission

Superuser permissions

## Storage directory

/etc/opt/jp1cons/

## Arguments

*logical-host-name*

When you are operating in a cluster system, this option specifies the name of the logical host where this command is to be executed. The permitted length is from 1 to 63 bytes characters. If this option is omitted, the command assumes the logical host name specified in the `JP1_HOSTNAME` environment variable. If the `JP1_HOSTNAME` environment variable is not specified, the command assumes the physical host name.

## Note

- If you want to execute this command as a remote shell command, disconnect standard input, standard output, and standard error output (assign `/dev/null` to standard input, standard output, and standard error output). Note that the remote shell command might not terminate even when processing for starting JP1/IM - Manager has finished.
- The `jco_start_cluster` command cannot be executed together with the `jco_spmd_status` command.

## Return values

|   |                                                                                                                     |
|---|---------------------------------------------------------------------------------------------------------------------|
| 0 | Normal termination                                                                                                  |
| 1 | More than one argument is specified, the event service is not running, or the IM database service cannot be started |
| 2 | There is no log directory                                                                                           |

# jco\_stop (UNIX only)

## Function

This command is a script for terminating JP1/IM - Manager automatically.

```
# cd /etc/opt/jplcons
# cp -p jco_stop.model jco_stop
```

Once the foregoing procedure has been executed, JP1/IM - Manager terminates automatically when the system terminates.

If the IM database service is running, the IM database service is stopped automatically after JP1/IM - Manager has terminated.

If you are using the intelligent integrated management database, after stopping the JP1/IM - Manager, terminate the trend data management service, then the intelligent integrated management database and finally terminate the IM database service.

If JP1/IM - Manager does not terminate, the command outputs the KAVB8800-E message to standard output.

If the IM database service does not terminate, the command outputs the KAVB8801-E message to standard output.

To stop JP1/IM - Manager manually, execute the /etc/opt/jplcons/jco\_stop.model script, or a file to which the script has been copied.

## Format

jco\_stop

## Execution permission

Superuser permissions

## Storage directory

/etc/opt/jplcons/

## Note

- Execute this command in an environment in which the environment variable JP1\_HOSTNAME has not been set. If you execute this command in an environment in which the environment variable JP1\_HOSTNAME has been set, the command will attempt to stop JP1/IM - Manager on the logical host that is set in the environment variable JP1\_HOSTNAME rather than on the physical host. Because this command does not support logical hosts, you must delete the environment variable JP1\_HOSTNAME if you want to stop JP1/IM - Manager on the physical host.
- The jco\_stop command cannot be executed together with the jco\_spmd\_status command.

## Return values

|   |                                                                                      |
|---|--------------------------------------------------------------------------------------|
| 0 | Normal termination                                                                   |
| 1 | More than one argument is specified or the termination request resulted in a timeout |

## Example 1

JP1/IM - Manager and the IM database service are running:

Input value:

```
jco_stop
```

Result:

```
KAVB3674-I Termination processing of JP1_CONS has started.  
KAVB3675-I The stop command terminated normally.  
KNAN11185-I Processing to stop the IM database service will now start.  
KNAN11028-I Please wait.  
KNAN11187-I The IM database service stopped normally.  
KNAN11186-I Processing to stop the IM database service ended normally.  
KNAN11188-I The status of the IM database service will now be confirmed.  
KNAN11183-I The IM database service is stopped.  
KNAN11189-I The status of the IM database service was successfully confirmed.
```

## Example 2

JP1/IM - Manager is running and the IM database service is not running:

Input value:

```
jco_stop
```

Result:

```
KAVB3674-I Termination processing of JP1_CONS has started.  
KAVB3675-I The stop command terminated normally.  
KNAN11188-I The status of the IM database service will now be confirmed.  
KNAN11183-I The IM database service is stopped.  
KNAN11189-I The status of the IM database service was successfully confirmed.
```

## Example 3

Neither JP1/IM - Manager nor the IM database service is running:

Input value:

```
jco_stop
```

Result:

```
KAVB3674-I Termination processing of JP1_CONS has started.  
KAVB3662-I The process management is not running.  
KNAN11188-I The status of the IM database service will now be confirmed.  
KNAN11183-I The IM database service is stopped.  
KNAN11189-I The status of the IM database service was successfully confirmed.
```

## Example 4

JP1/IM - Manager is not running and the IM database service is running:

Input value:

```
jco_stop
```

Result:

```
KAVB3674-I Termination processing of JP1_CONS has started.  
KAVB3662-I The process management is not running.  
KNAN11185-I Processing to stop the IM database service will now start.  
KNAN11028-I Please wait.  
KNAN11187-I The IM database service stopped normally.  
KNAN11186-I Processing to stop the IM database service ended normally.  
KNAN11188-I The status of the IM database service will now be confirmed.  
KNAN11183-I The IM database service is stopped.  
KNAN11189-I The status of the IM database service was successfully confirmed.
```

## Example 5

JP1/IM - Manager and the intelligent integrated management database are running:

Input value:

```
jco_stop
```

Result:

```
KAVB3674-I Termination processing of JP1_CONS has started.  
KAVB3675-I The stop command terminated normally  
KNAN12063-I Termination processing of Trend Data Management Service has started.  
KNAN12067-I Trend Data Management Service stopped normally.  
KNAN12065-I Processing to stop Trend Data Management Service ended normally.  
KNAN12064-I Termination processing of Intelligent Integrated DB Server has started.  
KNAN12068-I Intelligent Integrated DB Server stopped normally.  
KNAN12066-I Termination processing of Intelligent Integrated DB Server has started.
```

# jco\_stop.cluster (UNIX only)

## Function

When you are operating in a cluster system, this command terminates JP1/IM - Manager on the logical host.

After stopping the JP1/IM - Manager, if the intelligent integrated management database service and the trend data management service on the logical host are running, terminate the intelligent integrated management database service and the trend data management service. If the IM database service is running, terminate the IM database service.

When you execute this command, the JP1/IM - Manager processes, the trend data management service, the intelligent integrated management database service and the IM database service are terminated. If this command is executed but the processes do not terminate, use the `jco_killall.cluster` command to forcibly terminate all processes.

To execute this command, you must have executed `jplcc_setup_cluster` and `jplcs_setup_cluster` after installing and setting up JP1/IM - Manager.

If you want to use the intelligent integrated management database service or the trend data management service, you must set up the intelligent integrated management database.

For the IM database service to use, you must have set up the cluster system for that IM database service. For details about setting up a cluster system, see *Chapter 8. Operation and Environment Configuration in a Cluster System (for UNIX)* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

## Format

```
jco_stop.cluster [logical-host-name]
```

## Execution permission

Superuser permissions

## Storage directory

/etc/opt/jplcons/

## Arguments

*logical-host-name*

When you are operating in a cluster system, this option specifies the name of the logical host where this command is to be executed. The permitted length is from 1 to 63 bytes characters. If this option is omitted, the command assumes the logical host name specified in the `JP1_HOSTNAME` environment variable. If the `JP1_HOSTNAME` environment variable is not specified, the command assumes the physical host name.

## Note

The `jco_stop.cluster` command cannot be executed together with the `jco_spmd_status` command.

## Return values

|   |                                                                                      |
|---|--------------------------------------------------------------------------------------|
| 0 | Normal termination                                                                   |
| 1 | More than one argument is specified or the termination request resulted in a timeout |

# jcoappexecfcheck (Windows only)

---

## Function

This command checks the contents of a definition file for executing applications.

The definition file for executing applications in a specified directory is checked for any definition errors. Analysis results of the checking are output to standard output.

The analysis results are output in the following format:

```
application-execution-definition-identifier, execution-path[, text]
```

The analysis results contain the application execution definition identifier defined in the system ("default\_browser" indicating the default Web browser definition used in Central Console).

## Format

```
jcoappexecfcheck application-execution-definition-directory-name
```

## Execution permission

None

## Storage directory

*View-path*\bin\

## Arguments

*application-execution-definition-directory-name*

Specifies the directory containing the definition file for executing applications that is to be checked, expressed as an absolute path or a path relative to the current directory. This cannot be a file name.

## Example

Execute the command to check the following definition file:

```
@file type="application-execution-definition", version="0300";
@define-block type="application-execution-def";
id="notepad";
path="C:\winnt\system32\notepad.exe";
@define-block-end;
@define-block type="application-execution-def";
id="dmp";
path="[\HKEY_LOCAL_MACHINE\SOFTWARE\HITACHI\NETM/DM/P\0521/A\PathName\Path00]
\bin\DMPSTS.exe";
@define-block-end;
```

The analysis results are output as follows:

```
"dmp", "C:\NETMDMP\bin\DMPSTS.exe"
"notepad", "C:\winnt\system32\notepad.exe"
```

```
"default_browser", "C:\\Program Files\\Netscape\\Communicator\\Program\\netscape.exe"
```

# jcoattrfcheck

## Function

This command checks the contents of definition files for extended event attributes.

The definition files for extended event attributes that are in a specified directory are checked for any definition errors. Analysis results of the checking are output to standard output. Error information, such as definition errors, is output to standard error.

The command outputs the analysis results in CSV format. Each line contains the following information for one event ID:

```
platform,event-ID,language-type,product-name,attribute-name,display-name,type
```

### Note

The portion *, attribute-name, display-name, type* is output as many times as there are event attributes to be displayed.

When definition files for extended event attributes (extended file) are checked, the output of some of the fields is fixed. These fields are shown in the following table.

Table 1–28: Fixed values that are output when the extended files are checked

| No. | Field         | What is output                                                                                                                                |
|-----|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Platform      | base                                                                                                                                          |
| 2   | Event ID      | DEFAULT                                                                                                                                       |
| 3   | Language type | When extend_attr_ja.conf is checked: japanese<br>When extend_attr_en.conf is checked: english<br>When extend_attr_zh.conf is checked: chinese |
| 4   | Product name  | /HITACHI/DEFAULT                                                                                                                              |

JP1 event attributes displayed in the Event Details window contain this command's analysis results and the information common to the basic and extended attributes.

## Format

```
jcoattrfcheck extended-event-attribute-definition-directory-name
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In UNIX: None

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

```
/opt/jplcons/bin/
```

## Arguments

### *extended-event-attribute-definition-directory-name*

Specifies the name of the directory that contains the definition files for extended event attributes that are to be checked. Express the directory name as an absolute path or a path relative to the current directory.

Files to be checked must have the extension `.conf` and their file type will be `extended-attributes-definition`.

If you want to check definition files for extended event attributes (extended files), you must create an `extend` subdirectory in the directory specified in the argument of the `jcoattrfcheck` command and place the extended files in the `extend` directory. The files in the `extend` directory are checked as the extended files.

Note that, in checking the extended files, this command reads the standard files installed in JP1/IM - Manager and the extended file located in the directory specified in the argument of the `jcoattrfcheck` command, and checks whether the specified extended attributes are duplicated. The path of the standard files that are read when the extended file is checked is as follows:

In Windows

```
Console-path\conf\console\attribute\default.conf
```

In UNIX

```
/etc/opt/jplcons/conf/console/attribute/default.conf
```

## jcochafmode (UNIX only)

### Function

This command changes the location of the event acquisition filter from Event Console Service to Event Base Service.

If you execute this command while you are using an event acquisition filter (for compatibility), the filter becomes applicable to the automated action functions and to Central Scope, as well as to JP1 event monitoring. You can then define detailed filter conditions. However, if you want to use the event acquisition filter (for compatibility) as is, there is no need to change the filter location.

Information specified in the event acquisition filter version 07-00 or earlier, or the event acquisition filter (for compatibility) is inherited as shown in the table below. Change the settings and condition group names as appropriate to your operation.

Table 1–29: Inheritance of event acquisition filter settings

| Settings before execution of jcochafmode command    | After execution of jcochafmode command                                                                                                                                                                 |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| None                                                | Inherited as Existing conditions group with no settings                                                                                                                                                |
| Only event IDs are set                              | Inherited as Existing conditions group                                                                                                                                                                 |
| Only event levels are set                           | Inherited as Existing conditions group                                                                                                                                                                 |
| Only JP1/SES events are set                         | Inherited as Existing conditions group_SES                                                                                                                                                             |
| JP1/SES events and event IDs are set                | The JP1/SES event and event ID <sup>#</sup> settings are inherited as Existing conditions group_SES.<br>The event ID <sup>#</sup> settings are inherited as Existing conditions group.                 |
| Event levels and event IDs are set                  | Inherited as Existing conditions group                                                                                                                                                                 |
| JP1/SES events and event levels are set             | The JP1/SES event settings are inherited as Existing conditions group_SES.<br>The event level settings are inherited as Existing conditions group.                                                     |
| JP1/SES events, event levels, and event IDs are set | The JP1/SES event and event ID <sup>#</sup> settings are inherited as Existing conditions group_SES.<br>The event level and event ID <sup>#</sup> settings are inherited as Existing conditions group. |

#

The event ID settings are inherited to both condition groups.

### Format

```
jcochafmode [-h logical-host-name]
```

### Execution permission

Superuser permissions

### Storage directory

/opt/jp1cons/bin/

Note: This command is not included in JP1/IM - Manager for Linux.

## Arguments

`-h logical-host-name`

Specifies the logical host name for the event acquisition filter (for compatibility). If this option is omitted, the command assumes the physical host. If you do not use a cluster system, specification of this option is not needed.

## Notes

- If you wish to execute this command to change the location and definitions of an event acquisition filter, you must first terminate JP1/IM - Manager at the target host whose event acquisition filter is to be changed. If this command is executed while the JP1/IM - Manager is running, an error results.
- If you execute this command more than once, the converted event acquisition filter is overwritten and the customized condition definitions are discarded. Execute this filter only once when you convert an event acquisition filter.
- Once you convert an event acquisition filter, you can no longer restore the previous event acquisition filter or event acquisition filter (for compatibility) to the filter location and definitions existing before upgrading.
- An event acquisition filter version 08-01 or later cannot be converted to an event acquisition filter (for compatibility).
- If you have newly installed JP1/IM - Manager, there is no need to execute this command.
- If you change the location of an event acquisition filter to Event Base Service by executing this command, that filter becomes applicable to the correlation event generation function thereafter.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Example

Convert the event acquisition filter (for compatibility) at the logical `host01` to the event acquisition filter that is run on Event Base Service:

```
jcochafmode -h host01
```

## Output example 1

JP1/IM - Manager at the target host whose event acquisition filter is to be changed is not running:

```
KAVB1005-I The command (jcochafmode) has started.
KAVB0836-I The event acquisition filter was switched from interchangeability to the ordinary mode.
KAVB1002-I The command (jcochafmode) terminates normally.
```

## Output example 2

JP1/IM - Manager at the target host whose event acquisition filter is to be changed is running:

```
KAVB1005-I The command (jcochafmode) has started.
KAVB0831-E JP1/IM - Manager has started.
KAVB1003-I The command (jcochafmode) terminates abnormally.
```

## Function

This command changes the operating mode for the common exclusion-conditions of JP1/IM - Manager. Executing the command changes the common exclusion-conditions mode from *normal* to *extended*, and vice versa. If the mode is changed from *extended* to *normal*, common exclusion-conditions and additional common exclusion-conditions are not passed to the normal-mode common exclusion-conditions. To change the common exclusion-conditions mode to *extended*, the regular expressions of JP1/Base must be extended. For details about how to extend regular expressions of JP1/Base, see the *JP1/Base User's Guide*.

If you execute this command with the `-m` option specified, JP1/IM - Manager must not be running. If this command is executed without stopping JP1/IM - Manager, the command terminates with an error and a message is displayed.

In addition, multiple instances of this command cannot be executed concurrently.

Note that the operating mode of the common exclusion-conditions can be changed to *extended* when common exclusion-conditions have already been set.

The backup file of the extended definition file for the common exclusion-conditions is output as `common_exclude_filter_backup.conf` when either of the following applies:

- The operating mode is changed from *normal* to *extended*, and there is a problem with the regular expressions.
- The operating mode is changed from *extended* to *normal*.

The following shows the output destination of the backup file.

In Windows:

For a physical host:

`Console-path\conf\console\filter\`

For a logical host:

`shared-folder\jplcons\conf\console\filter\`

In UNIX:

For a physical host:

`/etc/opt/jplcons/conf/console/filter/`

For a logical host:

`shared-directory/jplcons/conf/console/filter/`

If there are regular expressions that cannot be used in extended mode, an error is displayed, and extended-mode common exclusion-conditions are not set. Edit the output file, and then use the `-ef` option of the `jcochfilter` command to apply the changes to JP1/IM - Manager.

For details about the extended definition file for common exclusion-conditions, see [Common-exclusion-conditions extended definition file](#) in *Chapter 2. Definition Files*.

For details about the `jcochfilter` command, see [jcochfilter](#) in *Chapter 1. Commands*.

## Format

```
jcochcefmode [-m {normal | extended}]  
              [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jplcons/bin/

## Arguments

`-m {normal | extended}`

Specifies the operating mode of the common exclusion-conditions.

- **normal**: Specify this value to set the operating mode of the common exclusion-conditions to normal mode. The default value is **normal**.

If the operating mode is changed back to *normal* from *extended*, the definition of normal-condition common exclusion-conditions becomes empty. The definition of the common exclusion-conditions used in extended mode is saved as a backup. In addition, all definitions of additional common exclusion-conditions are deleted. For details about backup files, see [Function](#).

- **extended**: Specify this value to set the operating mode of the common exclusion-conditions to extended mode. The definition for the common exclusion-conditions used in normal mode is passed to the definition of the extended-mode common exclusion-conditions. Note that if the operating mode of the common exclusion conditions is changed to extended mode, the regular expressions in JP1/Base must be extended, which will affect your ability to use those regular expressions in JP1/Base. For details about extended regular expressions in JP1/Base, see the *JP1/Base User's Guide*.

**normal** and **extended** are not case sensitive.

`-h logical-host-name`

For operation in a cluster system, this option specifies the logical host name. The operating mode for the specified host is set in the common exclusion-conditions for JP1/IM - Manager. If this option is omitted, the logical host name specified for the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

If JP1\_DEFAULT or a non-existent logical host is set for the JP1\_HOSTNAME environment variable, an error is displayed.

## Notes

- If the `-m` option is not specified, the operating mode in the common exclusion-conditions is displayed.
- If either of the following conditions, or both, applies, extended mode cannot be used:

- An event acquisition filter (for compatibility) is used
- Extended regular expressions are not used in JP1/Base on the manager host
- To change the operation mode of the common exclusion conditions on a logical host by using the `-h` option, a shared disk must be mounted.
- If you are using a cluster system, you must copy the common definition information from the active server to the standby server.  
For details about how to copy the information, see *7.8.2 Using commands to change settings (for Windows)* or *8.8.2 Using commands to change settings (for UNIX)* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.
- The `jcochcefmode` command cannot be executed together with the `jco_spmc_status` command.

## Return values

|     |                                                                                                                            |
|-----|----------------------------------------------------------------------------------------------------------------------------|
| 0   | Normal termination                                                                                                         |
| 1   | Abnormal termination                                                                                                       |
| 2   | Argument error                                                                                                             |
| 3   | JP1/IM - Manager is running                                                                                                |
| 4   | Prerequisite conditions for extended mode are not satisfied, or an event acquisition filter (for compatibility) is running |
| 5   | Prerequisite conditions for extended mode are not satisfied or regular expressions in JP1/Base are not extended            |
| 6   | The same operating mode as the current mode is specified                                                                   |
| 7   | No execution permission for the <code>jcochcefmode</code> command assigned (Windows only)                                  |
| 8   | Backup of the extended definition file for common exclusion-conditions failed                                              |
| 9   | Invalid logical host specification                                                                                         |
| 10  | Concurrent execution error                                                                                                 |
| 255 | Other error                                                                                                                |

## Example 1

Change the operating mode to normal mode:

Input value:

```
jcochcefmode -m normal
```

Result:

```
KAVB1005-I The command (jcochcefmode) has started.
KAVB0895-I The operation mode of the common exclusion conditions was changed to basic mode.
KAVB1002-I The command (jcochcefmode) terminates normally.
```

## Example 2

Change the operating mode to extended mode:

Input value:

```
jcochcefmode -m extended
```

Result:

```
KAVB1005-I The command (jcochcefmode) has started.  
KAVB0896-I The operation mode of the common exclusion conditions was changed to extended mode.  
KAVB1002-I The command (jcochcefmode) terminates normally.
```

### Example 3

Check the operating mode for the common exclusion-conditions (in this example, the name of the physical or logical host is hostA, and the operating mode is extended):

Input value:

```
jcochcefmode
```

Result:

```
KAVB1005-I The command (jcochcefmode) has started.  
KAVB0894-I The operation mode of the common exclusion conditions will be displayed. (host name = host A)  
operation mode = extended mode  
KAVB1002-I The command (jcochcefmode) terminates normally.
```

## Function

This command switches the event acquisition filter that is enabled in the correlation event generation function and Event Base Service of JP1/IM - Manager to the event acquisition filter indicated by a specified filter ID. In addition, the specified common exclusion-conditions can be enabled or disabled.

The command can display a list of the event acquisition filter's filter IDs, filter names, common exclusion-conditions group IDs, and common exclusion-conditions group names.

If JP1/IM - Manager is not running on the specified host, and an event acquisition filter (for compatibility) is used, this command cannot be used.

In addition, if the mode of the common exclusion-conditions is extended mode, the following operations can be performed:

- Enabling or disabling of the extended-mode common exclusion-conditions for each condition group
- Reading of the definition file for common exclusion-conditions and batch-application of the definitions for extended-mode common exclusion-conditions
- Reading of the definition file for the common exclusion-conditions and checking of the definitions for extended-mode common exclusion-conditions
- Enabling or disabling of the defined additional common exclusion-conditions group for each conditions group

## Format 1

```
jcochfilter [-i filter-ID]
            [-e [common-exclusion-conditions-group-ID
                [, common-exclusion-conditions-group-ID...] | ALL]]
            [-on common-exclusion-conditions-group-ID[, common-exclusion-con
ditions-group-ID...]]#
            [-off common-exclusion-conditions-group-ID[, common-exclusion-con
ditions-group-ID...]]#
            [-ef name-of-extended-definition-file-for-common-exclusion-con
ditions]#
            [-h logical-host-name]
```

#: Can be specified only for extended-mode common exclusion-conditions.

## Format 2

```
jcochfilter -check name-of-extended-definition-file-for-common-exclusion-con
ditions
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path\bin\*

In UNIX:

*/opt/jplcons/bin/*

## Arguments

**-i** *filter-ID*

Specifies the filter ID of the event acquisition filter to be switched.

**-e** [*common-exclusion-conditions-group-ID*, *common-exclusion-conditions-group-ID* . . . ] | ALL

Specifies the IDs of the common exclusion-conditions groups that you want to enable. The common exclusion-conditions whose group IDs are not specified will be disabled. If the common exclusion-conditions mode is extended mode, the ID of an additional common exclusion-conditions group can be specified. Separate multiple IDs with the comma. To enable all common exclusion-conditions, specify ALL.

You can specify the following values for *common-exclusion-conditions-group-ID*:

- Basic mode: 0 to 29
- Extended mode: 0 to 2,499

Note that if you specify nothing following **-e**, all common exclusion-conditions will be disabled. For the ID of an additional common exclusion-conditions group, specify a numeric value prefixed with A.

This option can be specified together only with the **-i** and **-h** options.

**-on** *common-exclusion-conditions-group-ID* [ , *common-exclusion-conditions-group-ID* . . . ]

Specifies the ID of the extended-mode common exclusion-conditions you want to enable or the ID of additional common exclusion-conditions. This option can be set only when the common exclusion-conditions mode is extended mode. If you specify multiple extended-mode common exclusion-conditions IDs, separate them with a comma (,).

You can specify the following values for *common-exclusion-conditions-group-ID*:

- Basic mode: 0 to 29
- Extended mode: 0 to 2,499

For the ID of an additional common exclusion-conditions group, specify a numeric value prefixed with A.

This option cannot be specified together with the **-e**, **-ef**, or **-check** option.

**-off** *common-exclusion-conditions-group-ID* [ , *common-exclusion-conditions-group-ID* . . . ]

Specifies the ID of the extended-mode common exclusion-conditions that you want to disable or the ID of additional common exclusion-conditions. This option can be set only when the common exclusion-conditions mode is extended mode. If you specify multiple extended-mode common exclusion-conditions IDs, separate them with a comma (,).

You can specify the following values for *common-exclusion-conditions-group-ID*:

- Basic mode: 0 to 29
- Extended mode: 0 to 2,499

For the ID of an additional common exclusion-conditions group, specify a numeric value prefixed with A.

This option cannot be specified together with the **-e**, **-ef**, or **-check** option.

**-ef** *name-of-extended-definition-file-for-common-exclusion-conditions*

Specifies the name of the definition file for common exclusion-conditions you want to apply to JP1/IM - Manager in relative or absolute path format. This option can be set only when the common exclusion-conditions mode is extended

mode. By specifying this option, you can batch-apply to JP1/IM - Manager the definitions of the extended-mode common exclusion-conditions described in the extended definition file for common exclusion-conditions<sup>#</sup>.

If an additional common exclusion-conditions group is set, all definitions are deleted. This option can be specified together only with the `-h` option.

<sup>#</sup>: The definition cannot be applied if the definition includes any environment-dependent character or other character that might cause character corruption.

`-check` *name-of-extended-definition-file-for-common-exclusion-conditions*

This option checks whether the definitions of the extended-mode common exclusion-conditions specified in the extended definition file for common exclusion-conditions are correct. This also checks whether the definitions include any environment-dependent character or other character that might cause character corruption.

Specify the name of the definition file for the common exclusion-conditions you want to apply to JP1/IM - Manager in relative or absolute path format. This option cannot be specified together with other options.

`-h` *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed. This option cannot be specified together with the `-check` option.

## Notes

- If `-h` is the only option specified, the following items are listed:
  - Filter IDs and filter names of the event acquisition filters that are currently enabled
  - IDs and names of the common exclusion-conditions groups currently enabled
  - Filter IDs and filter names of the event acquisition filters that have been set
  - IDs and names of the common exclusion-conditions groups that have been set
  - When the common exclusion-conditions operating mode is extended mode, the ID of the extended-mode common exclusion-conditions and the common exclusion-conditions group name
- If JP1/IM - Manager is not running at the specified host and the event acquisition filter is used for compatibility, the `jcochfilter` command cannot be executed.
- If you execute more than one `jcochfilter` command at the same time, it might cause an error depending on the timing.
- Executing the `jcochfilter` command concurrently many times might cause timeouts or a degraded performance of managers.
- The `jcochfilter` command cannot be executed together with the `jco_spmc_status` command.

## Return values

|   |                                                                                                |
|---|------------------------------------------------------------------------------------------------|
| 0 | Normal termination                                                                             |
| 1 | Argument error                                                                                 |
| 2 | Connection cannot be established with JP1/IM - Manager (Central Console) (communication error) |
| 3 | Operating status of JP1/IM - Manager cannot be verified                                        |
| 4 | There was no response from JP1/IM - Manager within a specific amount of time                   |
| 5 | Event acquisition filter is running in the compatibility mode                                  |
| 6 | Error from JP1/IM - Manager                                                                    |

|     |                                                                                                                                |
|-----|--------------------------------------------------------------------------------------------------------------------------------|
| 7   | Filter ID specified in the <code>-i</code> option does not exist                                                               |
| 8   | User does not have permissions to execute the <code>jcochfilter</code> command (Windows only)                                  |
| 9   | The maximum length for an event acquisition filter was exceeded                                                                |
| 10  | The common exclusion-conditions specified in the <code>-e</code> option do not exist                                           |
| 11  | The common exclusion-conditions group (extended mode) specified for the <code>-on</code> or <code>-off</code> option not found |
| 12  | The common exclusion-conditions group (extended mode) cannot be used (the setting is not for extended mode)                    |
| 13  | Application of the definition of common exclusion-conditions group (extended mode) failed                                      |
| 14  | The definition of common exclusion-conditions group (extended mode) contains an error                                          |
| 255 | Other error                                                                                                                    |

## Example 1

List the event acquisition filters on logical host `hostA`:

```
jcochfilter -h hostA
```

## Example 2

Change the filter ID of the event acquisition filter on logical host `hostA` to 3:

```
jcochfilter -i 3 -h hostA
```

## Example 3

Enable common exclusion-conditions groups (ID: 0, 2) for the event acquisition filter on the logical host (`hostA`), and disable all other groups:

```
jcochfilter -e 0,2 -h hostA
```

## Function

This command changes information about the response status for severe events.

The command accesses the event database on the host specified in `-h` and changes the response status of the JP1 events whose serial numbers are specified in `-n`.

When a response status is changed, the change is also applied to the response status displayed by other JP1/IM - Views that are logged in to the same manager. If a JP1 event whose response status is to be changed has been forwarded from another host or is set to be forwarded to another host, the response status is not changed at the source or target host.

This command can also be used to change the response status of JP1 events that are not displayed on the **Severe Events** page in the Event Console window. In such a case, you must use one of the following methods to check the change:

- If the JP1 event whose response status has been changed is displayed on the **Monitor Events** page in the Event Console window: Check the **Monitor Events** page.
- If the JP1 event whose response status has been changed is not displayed on the **Monitor Events** page in the Event Console window: Search for the event to check its status.

You can use this command while JP1/IM - Manager is running.

## Format

```
jcochstat [-h manager-host-name]  
          {-k severe-event-response-status-key | -d |  
          -k severe-event-response-status-key -d}  
          -n serial-number-1[, ..., serial-number-100]
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In UNIX: None

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jp1cons/bin/

## Arguments

`-h manager-host-name`

Specifies the manager that has the event database in which the severe events are registered. You can specify host names, domain names, and IPv4 addresses. If this option is omitted, the command assumes the logical host. If this option is omitted during cluster system operation, the command assumes the name of the physical host where the command is executed. If JP1/IM - Manager is not running at the specified manager, an error results.

Specify the manager host name as a string of from 1 to 255 characters.

Note that the ability to specify the manager of another host in *manager-host-name* is supported for compatibility with version 6.

**-k *severe-event-response-status-key***

Specifies the key value that represents the new severe event response status. The severe event response status of the severe events specified in the **-n** option is changed to the response status indicated by this key. If you use JP1/IM - View to display the status, the response status symbol changes.

A severe event response status key is case sensitive.

You must specify one or both of the **-k** and **-d** options. When both options are specified, the command changes the response status and then deletes the events from the JP1/IM - View window. The **-k** and **-d** options cannot both be omitted.

## Note

The concurrent execution of a large number of `jcochstat` commands can lead to the degradation of manager performance or cause the manager to time out.

For example, we recommend against executing the `jcochstat` command from an automated action or the like because, when the `jcochstat` command processing takes time, the processing of the action could also become delayed or the execution of the action could fail. Before incorporating the execution of the `jcochstat` command into your operation, carefully examine how the resulting operation can affect `jcochstat` command execution performance and manager performance to ensure that your operational needs are not compromised.

**Table 1–30: Severe event response status keys**

| Key value   | Response status | Response status symbol displayed in JP1/IM - View                                     |
|-------------|-----------------|---------------------------------------------------------------------------------------|
| PROCESSED   | Processed       |  |
| PROCESSING  | Being processed |  |
| HELD        | On hold         |  |
| UNPROCESSED | Unprocessed     | (No symbol)                                                                           |

**-d**

Deletes the severe events specified in the **-n** option on the **Severe Events** page of the Event Console window. These events are not deleted from the event database.

A deleted event can no longer be displayed on the **Severe Events** page.

You must specify either the **-k** or **-d** option, or both.

If you specify both options, change the response status first, and then delete the event on the **Severe Events** page of the Event Console window. You cannot omit both the **-k** and **-d** options.

**-n *serial-number***

Specifies the serial number of a severe event whose response status is to be changed. This option is mandatory. The permitted value is a decimal integer in the range from 0 to 2,147,483,647.

You can specify a maximum of 100 serial numbers. Separate multiple serial numbers with the comma. Do not specify any spaces before or after a delimiter comma.

## Return values

|   |                    |
|---|--------------------|
| 0 | Normal termination |
| 1 | Argument error     |

|     |                                                |
|-----|------------------------------------------------|
| 2   | Network failure                                |
| 3   | Updating of the event database failed          |
| 4   | Specified key is not supported                 |
| 5   | A specified event cannot be updated            |
| 7   | No permission to execute the command (Windows) |
| 255 | Other error                                    |

## Example

Change to processed status the response status of the events that are registered in the event database on the `host01` manager and whose serial numbers are 35 and 400, and then delete those events from the window:

```
jcochstat -h host01 -k PROCESSED -n 35,400 -d
```

# jcodbsetup

---

## Function

This is a setup command for creating an integrated monitoring database area for storing JP1 events. You must have already specified in advance in the setup information file the database's size, port number, and storage location.

In Windows, if this command is executed in an environment where the IM Configuration Management database is not set up, the following services are registered in the OS:

- When setting up a physical host: JP1/IM-Manager DB Server, JP1/IM-Manager DB Cluster Service
- When setting up a cluster configuration: JP1/IM-Manager DB Server\_*logical-host-name*, JP1/IM-Manager DB Cluster Service\_*logical-host-name*

In UNIX, if this command is executed in an environment where the IM Configuration Management database is not set up, an entry containing the path to the IM database is added to the `/etc/inittab` file. The entry is added to the respective physical and logical hosts on which this command was executed. Do not delete, edit, or comment out the entry in the `/etc/inittab` file that is added when this command is executed.

## Format

```
jcodbsetup {-f setup-information-file-name|-s}  
           [-h logical-host-name -c {online|standby}]]  
           [-q]  
           [-v 0]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jp1cons/bin/

## Arguments

`-f setup-information-file-name`

Specifies the setup information file that contains the requisite information, such as the IM database installation folder and the size of the database area. If neither the IM Configuration Management database nor an integrated monitoring database has been set up, you must specify this option. If the IM Configuration Management database has already been set up, specify in this option the setup information file that you specified when you set up the IM Configuration Management database. Alternatively, if the IM Configuration Management database has already been set up, you can specify the `-s` option instead. In such a case, the command uses the setup information that was specified when the IM Configuration Management database was set up.

This option cannot be specified together with the `-s` option. Additionally, the `-f` and `-s` options cannot both be omitted.

If the path contains a space, enclose the entire path in double-quotation marks ("). If you configure a cluster environment, specify the cluster setup information file name.

-s

If the IM Configuration Management database has already been set up, you can specify this option instead of the -f option. When this option is specified, the command sets up the integrated monitoring database by using the setup information that was specified when the IM Configuration Management database was set up.

If the IM Configuration Management database has not been set up but this option is specified, the command displays the KNAN11193-E message.

This option cannot be specified together with the -f option. Additionally, the -s and -f options cannot both be omitted.

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host that executes the command. The command sets up the integrated monitoring database for the specified logical host. If you do not use a cluster system, specification of this option is not needed. Note that this logical host name cannot be JP1\_DEFAULT. In addition, the logical host name is case sensitive. For the logical host name, specify a logical host name set in JP1/Base in the correct form, especially case.

-c {online|standby}

Specifies the setup type in the cluster configuration (primary node or secondary node). If you have specified the -h option, you must specify this option. If the IM Configuration Management database has already been set up on the same host, specify the value that you used when you created the IM Configuration Management database. If you are running a logical host in a non-cluster environment, specify *online*.

- *online*: Specifies that the primary node is to be set up.
- *standby*: Specifies that the secondary node is to be set up.

If you specify *online*, mount the shared disk and establish a connection to the logical host.

-q

Specifies that the command is to be executed without requesting confirmation from the user.

-v 0

Specifies that you want to recover a backup for expansion that was backed up using a table schema from JP1/IM - Manager 09-00 to 10-50. In JP1/IM - Manager 11-00, you can specify 0 as the version of the backup for expansion. When 0 is specified, the integrated monitoring database is set up using the same table schema as JP1/IM - Manager 09-00 to 10-50.

If the -v option is omitted, the integrated monitoring database is set up using the table schema of JP1/IM - Manager 11-00 or later.

The -v option is ignored if *standby* is specified for the -c option.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Notes

- The contents of the cluster setup information files must be identical between the primary and secondary nodes. When you set up the secondary node, copy the cluster setup information file used for the primary node and then use that file. If the contents of the files specified for the primary and secondary nodes are different, cancel the setup at the secondary node, copy the cluster setup information file from the primary node, and then re-execute the command.

- If you execute the command with the `-c` option specified, do not switch servers during execution. If you switch servers during execution, cancel the setup after the command has terminated, and then re-execute the command.
- If you have canceled the command's execution by pressing **Ctrl + C** or **Ctrl + Break**, make sure that the `pdistup`, `pdfmkfs`, `pddef`, and `pdload` processes are not executing, execute the `jcodbunsetup` command, and then re-execute this command.
- If the IM Configuration Management database has already been set up and the IM database is being used, JP1/IM - Manager Service must be stopped.
- If you are using the IM Configuration Management database in Windows, the IM database (JP1/IM3-Manager DB Server) must be running and the cluster service for the IM database (JP1/IM3-Manager DB Cluster Service) must be stopped.
- If you are using JP1/IM - MO, the JP1/IM - Message Optimizer service of JP1/IM - MO on the connection source must be stopped.
- Before executing the command, verify that the logical host name specified in the argument matches the JP1/Base logical host name in JP1/Base, and that the logical host name can be resolved.
- If you perform unsetup of the IM database by executing the `jcodbunsetup` or `jcfdbunsetup` command, you must restart the OS before re-executing the `jcfdbsetup` command.
- Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.

# jcodbunsetup

---

## Function

This command cancels setup of the integrated monitoring database that stores JP1 events.

Execute this command when you stop using the integrated monitoring database, uninstall JP1/IM - Manager, re-create the integrated monitoring database, or expand the database size.

In an environment in which an IM Configuration Management database has been set up, the IM Configuration Management database is still available even after execution of this command.

In Windows, if this command is executed in an environment where the IM Configuration Management database is not set up, the following services are deleted:

- When removing setup of a physical host: JP1/IM-Manager DB Server, JP1/IM-Manager DB Cluster Service
- When removing setup of a cluster configuration: JP1/IM-Manager DB Server\_*logical-host-name*, JP1/IM-Manager DB Cluster Service\_*logical-host-name*

In UNIX, if this command is executed in an environment where the IM Configuration Management database is not set up, entries in the `/etc/inittab` file registered by the `jcodbsetup` or `jcfdbsetup` command are deleted. The entries that are deleted are only those for processing related to the physical and logical hosts on which the command was executed.

## Format

```
jcodbunsetup [-h logical-host-name -c {online|standby}]  
              [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jp1cons/bin/

## Arguments

`-h` *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host that executes the command. The command cancels setup of the integrated monitoring database for the specified logical host. If you do not use a cluster system, specification of this option is not needed. Note that this logical host name cannot be `JP1_DEFAULT`. In addition, the logical host name is case sensitive. For the logical host name, specify a logical host name set in JP1/Base in the correct form, especially case.

`-c {online|standby}`

Specifies the type of setup being canceled in the cluster configuration (primary node or secondary node). If you have specified the `-h` option, you must specify this option.

- `online`: Specify this value if you specified `online` during setup of the integrated monitoring database.
- `standby`: Specify this value if you specified `standby` during setup of the integrated monitoring database.

If you specify `online`, mount the shared disk and establish a connection to the logical host. In addition, if you perform `unsetup` of the integrated monitoring database on a logical host running in a non-cluster environment, specify `online`.

`-q`

Specifies that the command is to be executed without requesting confirmation from the user.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Notes

- If you expand the database size in an environment in which the IM Configuration Management database has been created, you must execute the command that cancels setup of IM Configuration Management database after you've executed this command.
- If you execute the command with the `-c` option specified, do not switch servers during execution. If you switch servers during execution, re-execute the command after the command has terminated.
- If you have canceled the command's execution by pressing **Ctrl + C** or **Ctrl + Break**, make sure that the `pdirst` process is not executing, and then re-execute this command.
- In Windows, the service must be in the following status:

For a physical host:

The cluster service for the IM database (JP1/IM3-Manager DB Cluster Service) must be stopped, and the IM database service (JP1/IM3-Manager DB Server) must be started. In addition, if the IM Configuration Management database is set up and the IM database is being used, the JP1/IM - Manager service (JP1/IM3-Manager) must be stopped.

For a logical host:

The cluster service for the IM database (JP1/IM3-Manager DB Cluster Service\_*logical-host-name*) on the logical host must be stopped, and the IM database service (JP1/IM3-Manager DB Server\_*logical-host-name*) on the logical host must be started. In addition, when the IM Configuration Management database is set up and the IM database is being used, the JP1/IM - Manager service (JP1/IM3-Manager\_*logical-host-name*) must be stopped.

- In UNIX, when the IM Configuration Management database is set up, and the IM database is being used, the JP1/IM-Manager service must be stopped.
- If you are using JP1/IM - MO, the JP1/IM - Message Optimizer service of JP1/IM - MO on the connection source must be stopped.
- Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.

# jcoegschange

---

## Function

This command changes correlation event generation definitions. You can execute this command while the status of the correlation event generation function is stopped, running, or standby, but not while the status is starting or stopping.

The following notes apply to execution of the `jcoegschange` command:

- When you execute the `jcoegschange` command to change correlation event generation definitions, the new definitions take effect immediately. If there are JP1 events under correlation event generation processing when the new definitions take effect, all these events will fail.
- If no conditions are defined in the correlation event generation definition file when the `jcoegschange` command is issued, the command executes processing with no correlation event generation conditions. This means that no correlation events are issued.
- If the correlation event generation function is in running status and the correlation event generation definitions to be changed by the `jcoegschange` command contain an error, the definitions are not changed and processing continues.
- If the correlation event generation function is not running, the only processing that occurs is that the correlation event generation definitions are set. Once you start the correlation event generation function, the correlation event generation definitions take effect.
- The `jcoegschange` command cannot be executed together with the `jcoegsstatus` command in which the `-d` option is specified.

## Format

```
jcoegschange [-h logical-host-name]  
             -f correlation-event-generation-definition-file-name
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jp1cons/bin/

## Arguments

`-h` *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-f *correlation-event-generation-definition-file-name*

Specifies the relative or absolute path of the correlation event generation definition file.

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.

If you execute with standby host in UNIX / Linux, an unwanted directory named */shared-directory-name* is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- */shared-directory-name/jplcons*
- */shared-directory-name/jplcons/conf*
- */shared-directory-name/jplcons/conf/evgen*
- */shared-directory-name/jplcons/conf/evgen/system*

Delete */shared-directory-name* directory and files under it. Delete these unwanted directory and files, they will never to be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|     |                                                                                                                                                                                                              |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Correlation event generation definitions were changed successfully                                                                                                                                           |
| 1   | Attempt to change correlation event generation definitions failed                                                                                                                                            |
| 2   | A timeout occurred during communication with the Event Generation Service (when the integrated monitoring database is not used) or with Event Base Service (when the integrated monitoring database is used) |
| 100 | Execution permission error (Windows only)                                                                                                                                                                    |
| 101 | Argument error                                                                                                                                                                                               |
| 102 | Communication error                                                                                                                                                                                          |
| 255 | Other abnormal termination (system error)                                                                                                                                                                    |

## Example

Change the correlation event generation definitions for the physical host `hostP` to the definitions specified in the correlation event generation definition file `/tmp/teigil.conf`:

Input value:

```
jcoegschange -f /tmp/teigil.conf
```

Result:

```
KAJV3201-I The correlation event generation definition file (/tmp/teigil.conf) has been read, and the definitions for the correlation event generation function on (hostP) have been updated.
```

The same result is output even if no correlation event generation definitions are set for the correlation event generation function.

# jcoegscheck

---

## Function

This command checks the contents of a correlation event generation definition file.

This command looks for definition errors and redundant definitions in the correlation event generation definition file.

## Format

```
jcoegscheck -f correlation-event-generation-definition-file-name
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jplcons/bin/

## Arguments

**-f** *correlation-event-generation-definition-file-name*

Specifies the relative or absolute path of the correlation event generation definition file.

## Return values

|     |                                                                                                                    |
|-----|--------------------------------------------------------------------------------------------------------------------|
| 0   | Contents of the correlation event generation definition file were correct                                          |
| 1   | Correlation event generation definition file contained invalid contents                                            |
| 100 | No execution permissions (Windows only)<br>Execution permissions are only granted to <code>root</code> (UNIX only) |
| 101 | Argument error                                                                                                     |
| 255 | Other abnormal termination (system error)                                                                          |

## Example

Check the contents of correlation event generation definition file `/tmp/teigil.conf` at the physical host `hostP`:

Input value:

```
jcoegscheck -f /tmp/teigil.conf
```

**Result (when the definitions were correct):**

```
KAJV3311-I The content of the correlation event generation definition file (/tmp/teigil.conf) will now be checked.
KAJV3312-I No mistakes were found in the content of the correlation event generation definition file (/tmp/teigil.conf).
```

**Result (when there were errors in the definitions):**

```
KAJV3311-I The content of the correlation event generation definition file (/tmp/teigil.conf) will now be checked.
Contents of the correlation event generation definition file (/tmp/teigil.conf) are now checked.
KAJV3313-E There is an invalid definition in the correlation event generation definition.
KAJV3314-E There is an error in the contents of the correlation event generation definition file. (file name = /tmp/teigil.conf, line = 5, incorrect contents = The correlation event generation condition name has not been specified.)
KAJV3314-E There is an error in the contents of the correlation event generation definition file. (file name = /tmp/teigil.conf, line = 25, incorrect contents=The number of specified event conditions exceeds the maximum for a single correlation event generation condition.)
```

## Function

This command changes the status of the correlation event generation function from standby to running. When the correlation event generation function is placed in running status, it starts processing in accordance with the correlation event generation definitions.

You can use the `jcoegsstart` command only after you have used the `jcoegsstop` command to place the correlation event generation function on standby status. The `jcoegsstart` command cannot start the correlation event generation function when it is stopped (service start and stop are controlled by process management (`jco_spmd`)).

When the status is changed successfully by the `jcoegsstart` command, a JP1 event (00003F25) is issued. For details about the 00003F25 JP1 event, see [3.2.2 Details of JP1 events output by JP1/IM - Manager](#).

If the correlation event generation function is already in running status when the `jcoegsstart` command is executed, the status remains unchanged.

## Format

```
jcoegsstart [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jplcons/bin/

## Arguments

`-h logical-host-name`

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

## Return values

|     |                                                                                        |
|-----|----------------------------------------------------------------------------------------|
| 0   | Correlation event generation function restarted successfully                           |
| 1   | Restart of the correlation event generation function failed                            |
| 2   | A timeout occurred during communication with the correlation event generation function |
| 100 | No execution permissions (Windows only).                                               |

|     |                                                          |
|-----|----------------------------------------------------------|
|     | In UNIX, execution permissions are only granted to root. |
| 101 | Argument error                                           |
| 102 | Communication error                                      |
| 255 | Other abnormal termination (system error)                |

## Example

Restart the correlation event generation function at the physical host `hostP`:

Input value:

```
jcoegsstart
```

Result:

```
KAJV3291-I The correlation event generation function for hostP has rest
arted.
```

# jcoegsstatus

---

## Function

This command displays the status of the correlation event generation function and the start options. By using the options, you can also display the correlation event generation definitions that are currently in use and the date and time at which correlation event generation definitions were applied.

## Format

```
jcoegsstatus [-h logical-host-name]  
              [-d]
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In UNIX: None

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jp1cons/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-d

Specifies that the following are to be displayed: the status of the correlation event generation function, start options, correlation event generation definitions that are currently in use, and the date and time at which the correlation event generation definitions were applied by the jcoegschange command.

The jcoegsstatus command with the -d option specified cannot be executed together with the jcoegschange command.

## Output format

In Windows and UNIX (when the LANG environment variable is not C)

When you execute the jcoegsstatus command, the status of the correlation event generation function is displayed in the following format:

KAJV3261-I The status of the correlation event generation service for hostP  
will now be displayed.

Correlation event generation function: *status*

Start option : *start-option*

When the -d option is specified, the status is displayed in the following format:

KAJV3261-I The status of the correlation event generation service for hostP will now be displayed.

Correlation event generation function: *status*

Start option : *start-option*

KAJV3281-I The correlation event generation definition for hostP will now be displayed.

File name : *absolute-path-of-file*

Reflection time : *YYYY/MM/DD hh:mm:ss*

VERSION=0002

# *comment*

[*generation-condition-name*]

TARGET=*filtering-condition-for-the-correlation-target-range*

CON=*event-condition*

SAME\_ATTRIBUTE=*duplicate-attribute-value-condition*

CORRELATION\_NUM=*maximum-correlation-number*

TIMEOUT=*timeout-period*

TYPE=*event-correlation-type*

SUCCESS\_EVENT=*correlation-event-information*

In UNIX (when the LANG environment variable is C)

When you execute the jcoegsstatus command, the status of the correlation event generation function is displayed in the following format:

KAJV3261-I The status of the correlation event generation service for *host-name* will now be displayed.

Correlation event generation function : *status*

Start option : *start-option*

When the -d option is specified, the status is displayed in the following format:

KAJV3261-I The status of the correlation event generation service for *host-name* will now be displayed.

Correlation event generation function : *status*

Start option : *start-option*

KAJV3281-I The correlation event generation definition for *host-name* will now be displayed.

| STOP                                 | Stopped          | The correlation event generation function has stopped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

The following table lists and describes the character strings that are displayed as *start-option*.

**Table 1–32: Character strings displayed as start-option**

| Character string displayed as start-option | Start option | Description                                                                                                                                                |
|--------------------------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cold                                       | Cold start   | Do not inherit the information that was under correlation event generation processing when the function went into stop status during the previous session. |
| warm                                       | Warm start   | Inherit the information that was under correlation event generation processing when the function went into stop status during the previous session.        |

For details about the format of a correlation event generation definition file, see [Correlation event generation definition file](#) in *Chapter 2. Definition Files*.

## Return values

|   |                                                                                        |
|---|----------------------------------------------------------------------------------------|
| 0 | Status was displayed successfully                                                      |
| 1 | Status display failed                                                                  |
| 2 | A timeout occurred during communication with the correlation event generation function |

|     |                                                |
|-----|------------------------------------------------|
| 100 | No permission to execute the command (Windows) |
| 101 | Argument error                                 |
| 102 | Communication error                            |
| 255 | Other abnormal termination (system error)      |

## Example 1

Display the status of the correlation event generation function on the physical host `hostP` (status: running; start option: cold):

Input value:

```
jcoegsstatus
```

Result:

```
KAJV3261-I The status of the correlation event generation service for h
ostP will now be displayed.
Correlation event generation function : RUNNING
Start option                          : cold
```

## Example 2

Display the status of the correlation event generation function on the physical host `hostP` and the correlation event generation definitions (status: running; start option: cold):

Input value:

```
jcoegsstatus -d
```

Result:

```
KAJV3261-I The status of the correlation event generation service for h
ostP will now be displayed.
Correlation event generation function : RUNNING
Start option                          : cold

KAJV3281-I The correlation event generation definition for hostP will n
ow be displayed.
File name                            : /tmp/teigil.conf
Reflection time : 2005/11/05 20:35:30

VERSION=2
[CONDITION]
TARGET=B.SOURCESERVER==host1;host2;host3
CON=CID:1, B.ID==100, E.SEVERITY==Emergency;Critical;Alert;Error
SAME_ATTRIBUTE=B.SOURCESERVER
CORRELATION_NUM=20
SUCCESS_EVENT=B.ID:A00, E.SEVERITY:Emergency, B.MESSAGE:$EV1_B.MESSAGE
```

## Example 3

Display the status of the correlation event generation function on the physical host `hostP` and the correlation event generation definitions (status: standby; start option: warm):

The following condition applies:

- When JP1/IM - Manager is newly installed  
KAJV3283-I is displayed because the correlation event generation definition file has not been set.

Input value:

```
jcoegsstatus -d
```

Result:

```
KAJV3261-I The status of the correlation event generation service for h
ostP will now be displayed.
Correlation event generation function : STANDBY
Start option                          : warm

KAJV3283-I The correlation event generation definition for hostP has no
t been defined.
```

## Example 4

Display the status of the correlation event generation function on the physical host `hostP` and the correlation event generation definitions (status: stopped (process down); start option: cold):

Input value:

```
jcoegsstatus -d
```

Result:

```
KAJV3261-I The status of the correlation event generation service for h
ostP will now be displayed.
Correlation event generation function : STOP
Start option                          : cold

KAJV3281-I The correlation event generation definition for hostP will n
ow be displayed.
File name                            : /tmp/teigil.conf
Reflection time : 2005/11/05 20:35:30

VERSION=2
[CONDITION]
TARGET=B.SOURCESERVER==host1;host2;host3
CON=CID:1, B.ID==100, E.SEVERITY==Emergency;Critical;Alert;Error
SAME_ATTRIBUTE=B.SOURCESERVER
CORRELATION_NUM=20
SUCCESS_EVENT=B.ID:A00, E.SEVERITY:Emergency, B.MESSAGE:$EV1_B.MESSAGE
```

## Example 5

Load an invalid correlation event generation definition file while the correlation event generation function is running:

Input value:

```
jcoegsstatus -d
```

## Result:

```
KAJV3261-I The status of the correlation event generation service for h
ostP will now be displayed.
Correlation event generation function : RUNNING
Start option                          : cold

KAJV3281-I The correlation event generation definition for hostP will n
ow be displayed.
File name                            : /tmp/teigi1.conf
Reflection time : 2005/11/05 20:35:30

KAJV3285-I Operations will continue while ignoring an invalid correlat
ion event generation definition of hostP.

[CONDITION]
CON=CID:1, B.ID==ZZZ      ...#Message ID is invalid
SUCCESS_EVENT=B.ID:A00, E.SEVERITY:Emergency, B.MESSAGE:$EV1_B.MESSAGE
```

# jcoegsstop

---

## Function

This command changes the status of the correlation event generation function from running to standby. When the correlation event generation function is placed in standby status, it stops correlation event generation processing.

Use the `jcoegsstop` command when you want to stop correlation event generation processing without stopping the correlation event generation function. To restore the correlation event generation function to running status, either execute the `jcoegsstart` command or restart JP1/IM - Manager.

When the status is changed successfully by the `jcoegsstop` command, a JP1 event (00003F26) is issued. For details about the 00003F26 JP1 event, see [3.2.2 Details of JP1 events output by JP1/IM - Manager](#).

## Format

```
jcoegsstop [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jplcons/bin/

## Arguments

`-h logical-host-name`

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

## Notes

- If you execute this command during correlation event generation processing, all correlation events undergoing generation processing will result in failure.
- A JP1 event that is issued while the correlation event generation function is in standby status is not subject to correlation event generation processing.
- If the correlation event generation function is already in standby status when the `jcoegsstop` command is executed, the status remains unchanged.

## Return values

|     |                                                                                                                    |
|-----|--------------------------------------------------------------------------------------------------------------------|
| 0   | Correlation event generation function was terminated successfully                                                  |
| 1   | Termination of the correlation event generation function failed                                                    |
| 2   | A timeout occurred during communication with the correlation event generation function                             |
| 100 | No execution permissions (Windows only)<br>Execution permissions are only granted to <code>root</code> (UNIX only) |
| 101 | Argument error                                                                                                     |
| 102 | Communication error                                                                                                |
| 255 | Other abnormal termination (system error)                                                                          |

## Example

Terminate the correlation event generation function on the physical host `hostP`:

Input value:

```
jcoegsstop
```

Result:

```
KAJV3301-I The correlation event generation function for hostP has stopped.
```

## Function

This command outputs to a CSV file information about the JP1 events registered in the integrated monitoring database. Only one instance of this command can be executing at the same time.

The `jcoevtreport` command can output JP1 event information to a CSV file as long as the IM database service is running, even if the integrated monitoring database is disabled or Central Console is not running.

### ! Important

Because the `jcoevtreport` command acquires an event from the integrated monitoring database, operations such as searching for events from JP1/IM - View, switching response statuses, and acquiring events from JP1/IM - Manager are affected. Therefore, if the `jcoevtreport` command is executed when many events are running, other processes of JP1/IM - View or JP1/IM - Manager are delayed, and overall operation might be affected. If you want to execute the `jcoevtreport` command, do so during a time when it will not affect operation.

For details about the CSV output format, see *4.15.2 Saving event information in the integrated monitoring database (CSV report)* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

The command outputs error information to standard error, such as invalid definitions or a file size that exceeds the maximum value.

The following table describes the output functions.

| Function                          | Description                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output of event report            | Function that outputs to a CSV file information about the JP1 events registered in the integrated monitoring database                                                                                                                                                                                                                                   |
| Output of maintenance information | Function that outputs all information about the JP1 events registered between an output start date/time and an output end date/time in the event of an integrated monitoring database failure                                                                                                                                                           |
| Output-and-save                   | Function that saves JP1 event information from the output of event report function before the information is deleted from the integrated monitoring database                                                                                                                                                                                            |
| Output-and-save status display    | Function that displays the size and percentage of the JP1 events in the integrated monitoring database that have not been output and saved (percentage representing the ratio between the events that have not been output and the maximum number of records in the integrated monitoring database), as well as the deletion warning notification level |

## Format

### Output of event report

```
jcoevtreport [-h logical-host-name]
              [-o output-file-name]
              -s output-start-date -e output-end-date
              [-user]
              [-f filter-file-name-for-output-of-event-report]
              [-k item-file-name-for-output-of-event-report]
              [-t {ON|OFF}]
              [-a {EVTATTR|DISP}]
```

## Output of maintenance information

```
jcoevtreport [-h logical-host-name]  
             [-o output-file-name]  
             -s output-start-date -e output-end-date  
             -sys
```

## Output-and-save

```
jcoevtreport [-h logical-host-name]  
             [-o output-file-name]  
             -save  
             [-t {ON|OFF}]  
             [-a {EVTATTR|DISP}]
```

## Output-and-save status display

```
jcoevtreport [-h logical-host-name]  
             -showsv
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path*\bin\

In UNIX:

/opt/jp1cons/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host that executes the command. The command acquires JP1 event information from the integrated monitoring database that is running at the specified logical host and performs output of event reports, output of maintenance information, output-and-save, or output-and-save status display. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-o *output-file-name*

Specifies the relative or absolute path name of the CSV file to which the JP1 event information acquired from the integrated monitoring database is to be output.

If you specify a file name that begins with a hyphen (-), use a relative or absolute path that includes a directory (such as ./-hoge) in order to distinguish the file name from an option. The permitted file name is a maximum of 250 bytes including the path.

Note that the following characters cannot be specified in a file name in Windows:

- Characters: : ? " < > |

- A character string that completely matches any of the following strings (not case sensitive): CON, PRN, AUX, NUL, COM1, COM2, COM3, COM4, COM5, COM6, COM7, COM8, COM9, LPT1, LPT2, LPT3, LPT4, LPT5, LPT6, LPT7, LPT8, LPT9

The following describes the relationship between the specified output file name and the file name that is actually created.

Event information in the integrated monitoring database is output to a CSV file named *output-file-name\_serial-number.csv*. The serial number is a number from 000 to 999. A maximum of 50,000 event information items can be output to a file. If a file with the same name already exists, the command does not overwrite the file. Instead, the command creates a new file by incrementing the serial number until an unused file name is obtained. If the serial number exceeds 999, the command ends without creating a file. If this option is omitted, the command outputs a CSV file named *jcoevtreport\_serial-number.csv* to the current directory.

If the current directory (.) or the root directory (/) is specified in the file name, the command handles it as shown below:

| -o argument          | Windows                                        | UNIX                                          |
|----------------------|------------------------------------------------|-----------------------------------------------|
| .                    | ._xxx.csv is created in the current directory. | _xxx.csv is created in the current directory. |
| /                    | _xxx.csv is created in the root directory.     | _xxx.csv is created in the root directory.    |
| " " (null character) | _xxx.csv is created in the current directory.  | Insufficient argument error                   |

#### -s *output-start-date*

Specifies the start date/time of the event arrival time that is used for outputting events.

The specification format is *YYYYMMDDhhmmss*.

The specified date/time must be within the period from 1970/01/01 00:00:00 to 2099/12/31 23:59:59 (GMT). When the time zone of the host on which the command is executed is Japan, the period is (GMT + 9:00) 1970/01/01 09:00:00 to 2099/12/31 23:59:59.

#### -e *output-end-date*

Specifies the end date/time of the event arrival time that is used for outputting events .

The specification format is *YYYYMMDDhhmmss*.

The specified date/time must be within the same period as for the -s option.

#### -k *item-file-name-for-output-of-event-report*

Specifies the relative or absolute path name of the item file name for output of event report.

If you specify a file name that begins with a hyphen (-), use a relative or absolute path that includes a directory (such as ./-hoge) in order to distinguish the file name from an option.

For details about the format of the item file for event report output, see [Item file](#) in *Chapter 2. Definition Files*.

#### -f *filter-file-name-for-output-of-event-report*

Specifies the name of a filter file in relative or absolute path format.

If you specify a file name that begins with a hyphen (-), use a relative or absolute path that includes a directory (such as ./-hoge) in order to distinguish the file name from an option.

For details about the filter file formats, see [Filter file](#) in *Chapter 2. Definition Files*.

#### -t {ON|OFF}

Specifies whether the registration time, arrival time, and START\_TIME and END\_TIME (common information for the extended attributes) are to be output in the format *YYYYMMDDhhmmss* or in absolute time in seconds.

- ON: Specifies that the registration time, arrival time, and START\_TIME and END\_TIME (common information for the extended attributes) are to be output in the format *YYYYMMDDhhmmss* (i.e., they are to be converted from absolute time in seconds from January 1, 1970, to the calendar format *YYYYMMDDhhmmss*).

- OFF: Specifies that the time is not to be converted to the calendar format.

This option takes precedence over the item file specification.

ON and OFF are not case sensitive.

-a {EVTATTR|DISP}

Specifies the output format for the header. If the -a option is omitted, no header is output.

When EVTATTR is specified, the command displays attribute names (such as B.ID and E.SEVERITY); when DISP is specified, the command displays item names (such as event ID and severity).

EVTATTR and DISP are not case sensitive.

If DISP is specified in the -a option, the character string to be output varies according to the value set for the LANG environment variable. Note that the LANG environment variable that is used to display the character string in the header depends on the OS. In Windows, the language of the header character string will be the language of the OS. In UNIX, the LANG environment variable that is used is the variable of the prompt where the command is executed.

In addition, when program-specific extended attributes and user-defined item names are specified in the definition file for extended event attributes (extended file), you can assign one column per attribute for output to a CSV file, in the same way as for basic attributes and common extended attributes. You can also output the names of attributes and specified items to the header. For details about the CSV output format, see *4.15.2 Saving event information in the integrated monitoring database (CSV report)* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Specify whether you want to enable the function for assigning a column to each program-specific extended attribute for output in the environment definition file for event report output (evtreport.conf). For details, see *Environment definition file for event report output (evtreport.conf)* in *Chapter 2. Definition Files*.

The following table shows the character strings for the header that is output by the jcoevtreport command.

**Table 1–33: Header character string output by the jcoevtreport command**

| -a EVTATTR     | -a DISP                       |                               |
|----------------|-------------------------------|-------------------------------|
|                | LANG is Japanese              | LANG is English               |
| B.SEQNO        | Serial number                 | Serial number                 |
| B.ID           | Event ID                      | Event ID                      |
| B.PROCESSID    | Source process ID             | Source process ID             |
| B.TIME         | Registered time               | Registered time               |
| B.ARRIVEDTIME  | Arrived time                  | Arrived time                  |
| B.REASON       | Registered reason             | Registered reason             |
| B.USERID       | Source user ID                | Source user ID                |
| B.GROUPID      | Source group ID               | Source group ID               |
| B.USERNAME     | Source user name              | Source user name              |
| B.GROUPNAME    | Source group name             | Source group name             |
| B.SOURCESERVER | Registered host name          | Source event server name      |
| B.DESTSERVER   | Destination event server name | Destination event server name |
| B.SOURCEIPADDR | Source IP address             | Source IP address             |
| B.DESTIPADDR   | Destination IP address        | Destination IP address        |
| B.SOURCESEQNO  | Source serial number          | Source serial number          |
| B.CODESET      | Code set                      | Code set                      |

| -a EVTATTR                  | -a DISP                                              |                                                      |
|-----------------------------|------------------------------------------------------|------------------------------------------------------|
|                             | LANG is Japanese                                     | LANG is English                                      |

| Program-specific extended attributes count | Number of program-specific extended attributes <sup>#4</sup> | Program-specific extended attributes count |
| Program-specific extended attributes       | Program-specific extended attribute                          | Program-specific extended attribute        |

#1: The name of the attribute specified in the definition file for extended event attributes (extended file) will be output.

#2: The Japanese name of the item specified in the definition file for extended event attributes (extended file) will be output.

#3: The English name of the item specified in the definition file for extended event attributes (extended file) will be output.

#4: The total number of program-specific extended attributes that are not specified in the definition file for extended event attributes (extended file) will be output.

#### -user

Specifies that an event report on the JP1 events registered in the integrated monitoring database is to be output.

The `-user` option is optional.

If you omit all of the `-user`, `-sys`, `-save`, and `-showsv` options, the output of event report function is assumed.

#### -sys

Specifies that maintenance information on the JP1 events registered in the integrated monitoring database is to be output.

#### -save

Specifies that all JP1 events in the integrated monitoring database that have not been output and saved are to be output and saved.

#### -showsv

The following items are output.

| Display item                                       | Description                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Percentage of the events that have not been output | The percentage of the JP1 events in the integrated monitoring database that have not been saved and output (percentage representing the ratio between the events that have not been output and the maximum number of records in the integrated monitoring database) is displayed.                                                         |
| Size of the events that have not been output       | The data size of the JP1 events in the integrated monitoring database that have not been saved and output is displayed in megabytes.<br>The displayed size is the data size in the integrated monitoring database. For CSV output, capacity equivalent to the displayed size of the events that were not output $\times 1.2$ is required. |
| Deletion warning notification level setting        | The value set for the deletion warning notification is displayed.<br>If deletion warning notification is disabled, a hyphen (-) is displayed.                                                                                                                                                                                             |

## Return values

|     |                                                                |
|-----|----------------------------------------------------------------|
| 0   | Normal termination                                             |
| 1   | Invalid option or argument                                     |
| 2   | Invalid filter                                                 |
| 3   | Invalid item file                                              |
| 4   | Report output processing error                                 |
| 5   | Execution permission error (Windows only)                      |
| 6   | Concurrent execution error                                     |
| 7   | Serial number of the output file has reached the maximum value |
| 101 | Integrated monitoring database has not been set up             |
| 102 | IM database service is not running                             |
| 103 | Error occurred in the connection with the IM database service  |
| 254 | Memory shortage occurred                                       |
| 255 | System error                                                   |

## Notes

Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.

### Example 1

Output to a report the events that arrived at the manager from 2008/06/01 12:00:00 to 2009/01/01/00:00:00:

```
jcoevtreport -s 20080601120000 -e 20090101000000 -user
```

### Example 2

Set `report_xxx.csv` as the output destination and output an event report on the JP1 events dated from 2009/07/08 08:45:00 to 2009/07/14 17:15:00:

```
jcoevtreport -s 20090708084500 -e 20090714171500 -o report
```

### Example 3

Set `report_xxx.csv` as the output destination and output maintenance information on the JP1 events dated from 2009/07/08 08:45:00 to 2009/07/14 17:15:00:

```
jcoevtreport -sys -s 20090708084500 -e 20090714171500 -o report
```

### Example 4

Set `report_xxx.csv` as the output destination and perform output-and-save:

```
jcoevtreport -save -o report
```

## Example 5

Displays the output-and-save status:

```
jcoevtreport -showsv
```

# jcofuncfcheck (Windows only)

---

## Function

This command checks for definition errors in the definition files for executing applications and the definition file for the Tool Launcher window in a specified directory, and then outputs the analysis results to standard output.

The analysis results are output in the following formats:

Function tree definition

```
tree-hierarchy "displayed-character-string" [ , "execution-command-path" ]
```

Function toolbar definition

```
row = column
```

```
"displayed-character-string" [ , "execution-command-path" ]
```

Note:

The Function toolbar definition heading and information are displayed only when one of the following directories is specified as the Tool Launcher window definition directory:

*View-path*\conf\function\ja

*View-path*\conf\function\en

The analysis results contain the application execution definition identifier defined in the system ("default\_browser" indicating the default Web browser definition used in Central Console) and the Tool Launcher window identifier ("root" indicating the highest node of the menu tree).

## Format

```
jcofuncfcheck application-execution-definition-directory-name  
Tool-Launcher-window-definition-directory-name
```

## Execution permission

None

## Storage directory

*View-path*\bin\

## Arguments

*application-execution-definition-directory-name*

Specifies the directory containing the definition files for executing applications that are to be checked, expressed as an absolute path or a path relative to the current directory. This cannot be a file name.

*Tool-Launcher-window-definition-directory-name*

Specifies the directory containing the definition file for the Tool Launcher window that is to be checked, expressed as an absolute path or a path relative to the current directory. This cannot be a file name.

## Example

Execute the command on the following definition files:

### *Definition file for executing applications*

```
@file type="application-execution-definition", version="0300";
@define-block type="application-execution-def";
id="notepad";
path="C:\winnt\system32\notepad.exe";
@define-block-end;
@define-block type="application-execution-def";
id="dmp";
path="[\HKEY_LOCAL_MACHINE\SOFTWARE\HITACHI\NETM/DM/P\0521/A\PathName\Path00]
\bin\DMPSTS.exe";
@define-block-end;
```

### *Definition file for the Tool Launcher window*

```
@file type="function-definition", version="0300";
@define-block type="function-tree-def";
id="node1";
parent_id="root";
name="Node 1";
@define-block-end;
@define-block type="function-tree-def";
id="node11";
parent_id="node1";
name="Node 11";
icon="%JCO_INSTALL_PATH%\image\1206.gif";
execute_id="default_browser";
args="http://";
@define-block-end;
@define-block type="function-tree-def";
id="node2";
parent_id="root";
name="Node 2";
icon="%JCO_INSTALL_PATH%\image\1206.gif";
execute_id="notepad";
@define-block-end;
@define-block type="function-tree-def";
id="node3";
parent_id="root";
name="Node 3";
icon="%JCO_INSTALL_PATH%\image\1206.gif";
execute_id="dmp";
@define-block-end;
```

The analysis results are output as follows:

```
Function tree definition
  "Integrated Management"
    "Node-1"
      "Node 11", "C:\Program Files\Netscape\Communicator\Program\netscape.exe"
      "Node 2", "C:\winnt\system32\notepad.exe"
      "Node 3", "C:\NETMDMP\bin\DMPSTS.exe"
```

```
Function toolbar definition
```

```
row=1
```

```
"Node 11","C:\Program Files\Netscape\Communicator\Program\netscape.exe"
```

```
"Node 2","C:\winnt\system32\notepad.exe"
```

## Function

With the exception of the Central Scope Service (`jcsmain`), the Intelligent Integrated Management Base Service (`jddmain`), these commands outputs dumps in the event of a JP1/IM - Manager process failure. After executing the `jcogencore` command, you must restart JP1/IM - Manager.

The `jcogencore` command is not a command for regular use. Execute it if a hang-up occurs in a process or if you are instructed to do so in the course of investigation by support.

To detect failures, use the health check function of JP1/IM - Manager (for details about the health check function, see *9.2 JP1/IM - Manager health check function* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*).

When you execute the `jcogencore` command, it displays a message asking you to choose the processes for which failure data is to be output. Select the processes that have failed. The following table shows the files that are output when the `jcogencore` command is executed.

Table 1–34: Files that are output

| OS      | Process name            | Name of output file                          |                                                       |
|---------|-------------------------|----------------------------------------------|-------------------------------------------------------|
|         |                         | Java thread dump                             | Core dump                                             |
| Windows | evflow                  | <i>javacore-process-ID .XXXXXXXXXX.txt</i>   | --                                                    |
|         | jcmain                  | --                                           | --                                                    |
|         | evtcon <sup>#1</sup>    | <i>javacore-process-IDID .XXXXXXXXXX.txt</i> | --                                                    |
|         | evgen <sup>#1, #2</sup> | <i>javacore-process-ID .XXXXXXXXXX.txt</i>   | --                                                    |
|         | jcfmain                 | <i>javacore-process-ID .XXXXXXXXXX.txt</i>   | --                                                    |
| UNIX    | evflow                  | <i>javacore-process-ID .XXXXXXXXXX.txt</i>   | core.evflow                                           |
|         | jcmain                  | --                                           | core.jcmain                                           |
|         | evtcon <sup>#1</sup>    | <i>javacore-process-ID .XXXXXXXXXX.txt</i>   | core.java                                             |
|         | evgen <sup>#1, #2</sup> | <i>javacore-process-ID .XXXXXXXXXX.txt</i>   | core.evgen                                            |
|         | jcfmain                 | <i>javacore-process-ID .XXXXXXXXXX.txt</i>   | core.jcfmain<br>core. <i>process-ID</i> .jcfallogtrap |

Legend:

XXXXXXXXXX: Unique ID assigned automatically by the OS

--: Not output

#1

evtcon and evgen are function names.

#2

This function name is used when the integrated monitoring database is not used.

The output files are stored in the following folders:

When the process name is not `jcfmain`

*In Windows:*

Physical host: *Console-path*\log\

Logical host: *shared-disk*\jplcons\log\

*In UNIX:*

Physical host: /var/opt/jplcons/log/

Logical host: *shared-disk*/jplcons/log/

When the process name is `jcfmain`

*In Windows:*

Physical host: *Manager-path*\log\imcf\

Logical host: *shared-disk*\jplimm\log\imcf\

*In UNIX:*

Physical host: /var/opt/jplimm/log/imcf

Logical host: *shared-disk*/jplimm/log/imcf

In addition to the thread and core dumps that are output, other failure data can be obtained by using the data collection tool.

Once you have executed this command, you must restart JP1/IM - Manager.

- **In Windows:**

Physical host: After the command has executed, stop JP1/IM - Manager Service by choosing **Control Panel, Administrative Tools, Services, and JP1/IM-Manager Service**, and then restart JP1/IM - Manager. After JP1/IM - Manager has restarted, use the `jco_spmc_status` command to check the process statuses.

Logical host: After the command has executed, stop the JP1/IM-Manager\_*logical-host-name* service by choosing **Control Panel, Administrative Tools, and Services**, and then restart JP1/IM - Manager. If you use cluster software to monitor the JP1/IM-Manager\_*logical-host-name* service, use the cluster software to either restart the service or trigger failover.

- **In UNIX:**

Physical host: After the command has executed, the selected processes are terminated forcibly. Use the `jco_stop` command to terminate all processes and then restart the processes with the `jco_start` command. After the processes have restarted, use the `jco_spmc_status` command to check the process statuses.

Logical host: After the command has executed, the selected processes are forcibly terminated. Use the `jco_stop.cluster` command to terminate all processes and then restart the processes with the `jco_start.cluster` command. If you use cluster software to monitor JP1/IM - Manager, use the cluster software to either restart the service or trigger failover.

## Format

```
jcogencore [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Console-path\bin\*

In UNIX:

*/opt/jplcons/bin/*

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. The command outputs the thread or core dump of the JP1/IM - Manager processes at the specified logical host. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

## Notes

- When you execute the `jcogencore` command in UNIX, the processes are terminated forcibly after the dump has been output. Execute this command only in the event of process hang-up. You can use health checking to detect process hang-ups.  
Take precautions when you execute the `jcogencore` command during cluster system operation.
- Before you execute this command in UNIX, first check the available disk space on your machine. If you output a core dump for five processes (`jcmain` excluded), the total size of the core dump might be as much as 8,419 megabytes. In addition, if you output a core dump for `jcmain`, the total size of the core dump might be as much as of  $560 + 230 \times \text{number-of-jcfallogtrap-processes}$  megabytes.
- If multiple processes have failed, execute the following commands in the order at which they are listed:  
In Windows: Event Console Service (`evtcon`), Event Base Service (`evflow`)  
In UNIX: Event Console Service (`evtcon`), Automatic Action Service (`jcmain`), Event Base Service (`evflow`)  
You can execute the command on the correlation event generation function (`evgen`) and the IM configuration management service (`jcmain`) in any order because there are no dependencies with other processes.
- In UNIX, the `jcogencore` command might not generate core dump files if the operating system is configured to block core dump files from being generated.  
For details about the settings for core dump files, see *2.18.10 Specifying settings for handling JP1/IM - Manager failures (for UNIX)* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

## Return values

|    |                                           |
|----|-------------------------------------------|
| 0  | Normal termination                        |
| 1  | Option or argument analysis error         |
| 2  | Process check error                       |
| 3  | Logical host error                        |
| 4  | Execution permission error (Windows only) |
| 5  | Pipe creation error (Windows only)        |
| 6  | Thread dump output processing error       |
| 10 | Other error                               |

## Example 1

Execute the command because a hang-up occurred in the Event Console Service (evtcon) process on the physical host in Windows:

```
jcogencore
```

## Example 2

Execute the command because a hang-up occurred in the Event Console Service (evtcon) process on the logical host hostA in Windows:

```
jcogencore -h hostA
```

## Example 3

Execute the command because a hang-up occurred in the Event Console Service (evtcon) process on the physical host in UNIX:

```
/opt/jplcons/bin/jcogencore
```

## Example output

When a hang-up occurred in the Event Console Service (evtcon) process on the physical host in UNIX, and core and thread dumps were output:

```
ProcessName      PID
[1] : evflow      1234
[2] : jcamain     94320
[3] : evtcon      3333
[4] : evgen       65654
[6] : jcfmain     3316
[7] : Exit
KAVB8427-I When outputting dumps for the three processes evflow, jcamain, and
d evtcon at the same time, output the dumps in order of evtcon, jcamain, and
d evflow.
KAVB8417-I Please enter a number for the process to output the core dump file
e [1-7]:3
KAVB8414-I The thread dump output request has been sent.
KAVB8407-I When the core dump is output, evtcon will stop. Is this OK? (y/n)
:y
KAVB8406-I The core dump file will be output.
KAVB8416-I The core dump file has been output.
```

## Function

This command tests the health check definition file (`jcohc.conf`) that is used by the health check function of JP1/IM - Manager to determine whether the specified definitions will execute correctly. You can test the notification command on the basis of the health check definition file.

The `jcohtest` command can be executed only when JP1/IM - Manager is running.

If you have made changes to the health check definition file (`jcohc.conf`), you cannot execute the `jcohtest` command unless you have first applied the new settings in the health check definition file by means of a method such as executing the `jco_spmd_reload` command.

During testing by the `jcohtest` command, the variables specified in the health check definition file (`HCHOST`, `HCFUNC`, `HCPNAME`, `HCPID`, `HCDATE`, and `HCTIME`) are displayed as shown below.

Table 1–35: Values displayed during execution of the `jcohtest` command

| Variable name        | Value displayed during execution of the <code>jcohtest</code> command           |
|----------------------|---------------------------------------------------------------------------------|
| <code>HCHOST</code>  | Physical host name or logical host name specified in the <code>-h</code> option |
| <code>HCFUNC</code>  | <code>evflow</code>                                                             |
| <code>HCPNAME</code> | <code>evflow</code>                                                             |
| <code>HCPID</code>   | Process ID of <code>evflow</code>                                               |
| <code>HCDATE</code>  | Notification command execution date ( <code>YYYY/MM/DD</code> )                 |
| <code>HCTIME</code>  | Notification command execution time ( <code>hh:mm:ss</code> )                   |

For details about the health check definition file (`jcohc.conf`), see [Health check definition file \(`jcohc.conf`\)](#) in *Chapter 2. Definition Files*.

## Format

```
jcohtest [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

`Console-path\bin\`

In UNIX:

`/opt/jplcons/bin/`

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. The command tests the notification command that is set in the health check definition file for the specified logical host. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

## Return values

|    |                                           |
|----|-------------------------------------------|
| 0  | Normal termination                        |
| 1  | Argument error                            |
| 2  | Logical host does not exist               |
| 3  | Notification command execution failure    |
| 7  | Execution permission error (Windows only) |
| 10 | Other error                               |

# jcoimdef

---

## Function

This command sets up a system environment for JP1/IM - Manager or references settings.

When this command is executed, the settings are output to standard output.

For details about the setting values that are enabled by setting the `-i` option, see the description for the `-i` option.

## Format

```
jcoimdef  [-r {EXE | OUTPUT | OFF}]
          [-b event-acquisition-location]
          [-s {ON | OFF}]
          [-egs {ON | OFF}]
          [-resevent {ON | OFF}]
          [-e retry-interval]
          [-t timeout-period]
          [-c retry-count:retry-interval]
          [-o retry-count:retry-interval]
          [-i]
          [-h logical-host-name]
          [-memo {ON | OFF}]
          [-chsev {ON | OFF}]
          [-db {ON | OFF}]
          [-dbntc {ON | OFF}]
          [-dbntcpas deletion-warning-notification-level]
          [-cf {ON | OFF}]
          [-cmdbtn {ON | OFF}]
          [-hostmap {ON | OFF}]
          [-bizmonmode {ON | OFF}]
          [-ignorecasehost {ON | OFF}]
          [-storm {ON | OFF}]
          [-dd {ON | OFF}]
```

The `-resevent` option is used for linking with BJEX or JP1/AS. For details about the `-resevent` option, see *11.5.1 jcoimdef* in the *JP1/Integrated Management 3 - Manager Administration Guide*.

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

`Console-path\bin\`

In UNIX:

`/opt/jp1cons/bin/`

## Arguments

### *No arguments specified*

Specifies that a list of current settings is to be displayed at standard output.

The display format is as follows:

### *setting-item-name=setting*

The figure below shows the information that is output by this command when the default values are used. You can change the settings for the items by specifying arguments.

Figure 1–1: jcoimdef command output format

|                                     |                                                                                                                                         |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| F_TIME_TO_GO_BACK=-1                | Event acquisition start position (specified in -b)                                                                                      |
| F_EVENT_CONNECT_RETRY_INTERVAL=10   | Retry interval at which connection establishment with Event Service is retried automatically (specified in -e)                          |
| F_DISPATCH_CONNECT_RETRY_COUNT=30   | } Retry count and retry interval at which connection establishment is retried automatically during event transmission (specified in -c) |
| F_DISPATCH_CONNECT_RETRY_INTERVAL=2 |                                                                                                                                         |
| F_DISPATCH_TIME_OUT=60              | Timeout period for automatic transmission retry processing (specified in -t)                                                            |
| F_DISPATCH_RETRY_COUNT=3            | } Retry count and retry interval at which event transmission is retried automatically (specified in -o)                                 |
| F_DISPATCH_RETRY_INTERVAL=0         |                                                                                                                                         |
| F_CS=OFF                            | Whether events are transmitted to Central Scope Service (specified in -s)                                                               |
| A_REEXECUTE_RUNNING_ACTION=OFF      | Setting for the Automatic Action Service (specified in -r)                                                                              |
| S_EGS=OFF                           | Whether Event Generation Service is started (specified in -egs)                                                                         |
| A_RULE=OFF                          | Whether the JP1/IM - Rule Operation linkage items are displayed (specified in -rule)                                                    |
| A_RULE_HOST=                        | Host name of the linked JP1/IM - Rule Operation (specified in -rulehost)                                                                |
| A_RULE_USER=                        | Name of user who executes the linked JP1/IM - Rule Operation (specified in -ruleuser)                                                   |
| S_RESEVENT=OFF                      | Setting for the response-waiting event management function (specified in -resevent)                                                     |
| S_MEMO=OFF                          | Setting for memo entry setting function (specified in -memo)                                                                            |
| S_CHANGE_SEVERITY=OFF               | Whether the severity changing function is enabled or disabled (specified in -chsev)                                                     |
| S_DB=OFF                            | Whether the event storage function is enabled or disabled (specified in -db)                                                            |
| S_DBNTC=OFF                         | Whether deletion warning notification events are issued (specified in -dbntc)                                                           |
| S_DBNTCPOS=80                       | Setting for the deletion warning notification position as a percentage (specified in -dbntcpos)                                         |
| S_CF=OFF                            | Whether IM Configuration Management Service is started (specified in -cf)                                                               |
| S_CMDBTN=OFF                        | Whether the command button is enabled (specified in -cmdtn)                                                                             |
| S_HOSTMAP=OFF                       | Whether the event source host mapping feature is enabled (specified in -hostmap)                                                        |
| S_BIZMONMODE=OFF                    | Whether restrictions on referencing and operating business groups are enabled (specified in -bizmonmode)                                |
| S_IGNORECASEHOST=OFF                | Whether the case is distinguished when event conditions related to host names are compared (specified in -ignorecasehost)               |
| S_STORM=OFF                         | Whether the repeated event monitoring suppression function is enabled (specified in -storm)                                             |
| S_DD=OFF                            | Whether the Intelligent Integrated Management Base is enabled (specified in -dd)                                                        |

Legend:

\_\_\_ (underscore): Indicates the default.

-r {EXE | OUTPUT | OFF}

This option is used for setting Automatic Action Service. For the option, specify the operation of an action whose status is any of the following when Automatic Action Service starts:

- Wait

- Wait (being canceled)
- Wait (cancellation failed)
- Sending
- Sending (being canceled)
- Sending (cancellation failed)
- Queuing
- Queuing (being canceled)
- Queuing (cancellation failed)
- Running
- Running (being canceled)
- Running (cancellation failed)

When EXE is specified, actions whose status is any of the above are re-executed. When the status of such an action is displayed in the Action Log window (or by executing the `jcashowa` command), the displayed status name contains `-R`.

OUTPUT: Outputs a list of actions whose status is any of the above to the action re-execution file (`actreaction`).

When the status of such an action is displayed (by a method such as executing the `jcashowa` command or in the Action Log window), `Ended -R` is displayed as the status.

As many sets of the following information items are output as there are actions in the action re-execution file:

```
### date#Δtime#Δevent-IDΔserial-number ### [linefeed]
[u=execution-user-name] [e=environment-variable-file-name] [d=execution-host-name]
execution-command [linefeed]
```

#: Date and time the re-execution function was executed.

OFF: Performs no processing for actions whose status is any of the above and leaves the action as is.

#### `-b event-acquisition-start-position`

Specifies the position at which event acquisition is to start when JP1/IM - Manager starts. The permitted value is from `-1` to `144`.

If you specify `-1`, processing continues from the status existing the last time JP1/IM - Manager was terminated. The default is that `-1` is set.

For example, if `-1` is specified, JP1/IM - Manager has received events through serial number `12000`, events with serial numbers from `10001` to `12000` (2,000 events) have been stored in the event buffer, and JP1/IM - Manager is restarted, the following takes place:

- Event buffer of JP1/IM - Manager:  
The events that were in the event buffer the last time JP1/IM - Manager was terminated (events with serial numbers from `10001` to `12000`) are stored in the event buffer again.
- Automated action:  
Automated action is performed on the events starting with the event (serial number `12001`) that immediately follows the event with serial number `12000`. The automated action processing involves matching events with action definitions.

If you specify `0`, acquisition processing starts from the first event that is registered after JP1/IM - Manager starts.

- Event buffer of JP1/IM - Manager:  
The events that are registered in the event database after the start are stored in the event buffer.
- Automated action:

The events that are registered in the event database after the start are subject to automated action processing.

If you specify a value in the range from 1 to 144, the command acquires the events from the event database starting with the event that was registered at the specified number of hours before JP1/IM - Manager started.

This value is in units of hours. For example, to collect events starting from an event that was registered 1 hour before JP1/IM - Manager startup, specify 1.

- Event buffer of JP1/IM - Manager:

The events that have been registered in the event database at the manager since the specified number of hours before the startup are stored in the event buffer.

- Automated action:

The events that have been registered in the event database at the manager since the specified number of hours before the startup are subject to automated action processing.

Note that an event that has already been processed by an automated action is no longer subject to automated action processing. In other words, action matching is performed only once per event.

In all cases, the events that are transmitted to Central Scope Service are the same as for the automated actions.

`-s {ON | OFF}`

Specifies whether Central Scope Service is to be started and whether events are to be transmitted to Central Scope Service.

If you specify `ON`, Central Scope Service starts when JP1/IM - Manager starts and events are transmitted to Central Scope Service. Also, in the Event Console window, the **Central Scope** button and menu are enabled.

If you specify `OFF`, events cannot be set to be transmitted to Central Scope Service because Central Scope Service is not started when JP1/IM - Manager starts. In this case, the **Central Scope** button and menu are disabled in the Event Console window. The default is `OFF`.

To enable the `-s` setting, you must also restart the connected JP1/IM - View.

`-egs {ON | OFF}`

Specifies whether the correlation event generation function is to be enabled.

If you specify `ON`, the following occurs when JP1/IM - Manager starts:

- If the integrated monitoring database is not used, the Event Generation Service is started.
- If the integrated monitoring database is used, the correlation event generation function of Event Base Service is enabled.

If you specify `OFF`, the following occurs when JP1/IM - Manager starts:

- If the integrated monitoring database is not used, the Event Generation Service is not started.
- If the integrated monitoring database is used, the correlation event generation function of Event Base Service is disabled.

The default is `OFF`.

`-resevent {ON | OFF}`

Specifies whether to enable the response-waiting event management function.

If you specify `ON`, the response function for JP1/IM - Manager events is enabled.

If you specify `OFF`, the response function for JP1/IM - Manager events is disabled. The default is `OFF`. The value set for this command takes effect when JP1/IM - Manager has been restarted, in which case you must also restart the connected JP1/IM - View. You cannot use the `-i` option or the `jco_spmc_reload` command to enable or disable the response-waiting event management function.

-e *retry-interval*

Specifies the interval at which connection establishment with the event service is to be retried automatically when a connection establishment attempt fails or connection is lost while the event service is acquiring events from Event Base Service. The permitted value is from 1 to 86,400 (seconds). This is a setting for Event Base Service.

-t *timeout-period*

Specifies the timeout period for retry processing when event transmission from Event Base Service to Central Scope Service or Event Console Service fails and automatic transmission is retried. The permitted value is from 1 to 3,600 (seconds). When Event Base Service issues a transmission request to Central Scope Service or Event Console Service and there is no response within the time specified in this option, Event Base Service stops event transmission to that control. This is a setting for Event Base Service.

-c *retry-count:retry-interval*

Specifies a retry count and a retry interval at which connection establishment is to be retried automatically if an attempt to establish connection with Central Scope Service or Event Console Service, fails or if connection is lost when events are transmitted from Event Base Service to Central Scope Service or Event Console Service. The permitted retry count is from 0 to 100, and the permitted retry interval is from 0 to 3600 (seconds). This is a setting for Event Base Service.

-o *retry-count:retry-interval*

Specifies a retry count and a retry interval at which events are to be transmitted automatically when event transmission from Event Base Service to Central Scope Service or Event Console Service fails. The permitted retry count is from 1 to 100, and the permitted retry interval is from 0 to 3600 (seconds). This is a setting for Event Base Service.

-i

Specifies that the values of the specified options are to be enabled. When this option is specified, the values set in the options specified in this command are loaded into Event Base Service and the Automatic Action Service and those values take effect.

The following options can be applied immediately by using the -i option:

- -e
- -t
- -c
- -o
- -memo
- -cmdbtn

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. The command sets up the system environment of JP1/IM - Manager at the specified logical host or references the settings for the specified logical host. However, the local host inherits the system environment from the physical host. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-memo {ON | OFF}

Specifies whether the memo entry setting function is to be used.

If the integrated monitoring database is enabled and ON is specified in this option, the memo entry setting function is enabled. If OFF is specified, the memo entry setting function is disabled. If the integrated monitoring database is disabled, specifying ON in this option will not enable the memo entry setting function. The default is OFF.

`-chsev {ON | OFF}`

Specifies whether the severity changing function is to be used.

If the integrated monitoring database is enabled and ON is specified in this option, the severity changing function is enabled. If OFF is specified, the severity changing function is disabled. If the integrated monitoring database is disabled, specifying ON in this option will not enable the severity changing function. The default is OFF.

`-db {ON | OFF}`

Specifies whether the event storage function is to be used.

- ON: Enable the event storage function; events can be stored in the integrated monitoring database.
- OFF: Disable the event storage function; events cannot be stored in the integrated monitoring database.

If the integrated monitoring database is disabled, specifying ON in this option will not enable the event storage function. The default is OFF.

If you want to specify ON, you must set up the integrated monitoring database.

If you start JP1/IM - Manager when the integrated monitoring database has not been set up, or when the IM database service is not running, Event Base Services outputs a message to the integrated trace log, and terminates abnormally.

`-dbntc {ON | OFF}`

Specifies whether a deletion warning notification event is to be issued when the number of JP1 events (expressed as the percentage of the maximum number of records in the integrated monitoring database) in the integrated monitoring database on which output-and-save has not been performed exceeds the deletion warning notification level.

- ON: Issue a deletion warning notification event when the ratio of JP1 events in the integrated monitoring database on which output-and-save has not been performed exceeds the deletion warning notification level.
- OFF: Do not issue a deletion warning notification event even if the ratio of JP1 events in the integrated monitoring database on which output-and-save has not been performed exceeds the deletion warning notification level. The default is OFF.

If the integrated monitoring database is disabled, specifying ON in this option will not result in issuance of a deletion warning notification event if the ratio of JP1 events in the integrated monitoring database on which output-and-save has not been performed has exceeded the deletion warning notification level.

`-dbntcps deletion-warning-notification-level`

Specifies the number of JP1 events (expressed as the percentage of the maximum number of records in the integrated monitoring database) in the integrated monitoring database on which output-and-save has not been performed that is to trigger issuance of a deletion warning notification event.

The permitted value range is from 20 to 80 (%). The default is 80.

For example, if you specify `-dbntcps 70`, the deletion warning notification level is set to 70%.

`-cf {ON | OFF}`

Specifies whether IM Configuration Management Service is to be started.

- ON: Start IM Configuration Management Service when JP1/IM - Manager starts.
- OFF: Do not start IM Configuration Management Service when JP1/IM - Manager starts. The default is OFF.

If you specify ON, make sure that IM Configuration Management has already been set up.

If you start JP1/IM - Manager when IM Configuration Management has not been set up or the IM database service has not started, Event Base Services outputs a message to the integrated trace log, and terminates abnormally.

`-cmdbtn {ON | OFF}`

Specifies whether to enable the command button in the Execute Command window.

- ON: Enables the command button. When enabled, the command button is displayed in the Execute Command window. By default, ON is set.

- **OFF:** Disables the command button. When disabled, the command button is not displayed in the Execute Command window.

`-hostmap {ON | OFF}`

Specifies whether to enable mapping on the event source host.

- **ON:** Enables mapping on the event source host.
- **OFF:** Disables mapping on the event source host. By default, **OFF** is set.

If the integrated monitoring database is disabled, mapping on the event source host will be disabled even when **ON** is specified.

`-bizmonmode {ON | OFF}`

Specifies whether to enable restrictions on referencing and operations by business groups.

- **ON:** Enables restrictions on referencing and operations by business groups.
- **OFF:** Disables restrictions on referencing and operations by business groups. By default, **OFF** is set.

If the integrated monitoring database, the IM Configuration Management service, or mapping on the event source host is disabled, restrictions on referencing and operations by business groups will be disabled even when **ON** is specified.

`-ignorecasehost {ON | OFF}`

Specifies whether to distinguish letter case when event conditions related to a host name are compared.

- **ON:** Letter case is ignored. However, if regular expressions are used in the comparison keyword, uppercase and lowercase are distinguished.
- **OFF:** Letter case is distinguished. By default, **OFF** is set.

The following table describes the correspondence between functions and attributes for which the case of a host name is ignored when this option is enabled.

**Table 1–36: Correspondence between functions and event conditions**

| Function                                                                                 | Attribute (event condition)                                                                                                                                                                                                                                                                    |

`-storm {ON | OFF}`

Specifies whether to enable the repeated event monitoring suppression function.

- ON: Enables the repeated event monitoring suppression function.
- OFF: Disables the repeated event monitoring suppression function. The default is OFF.

If you specify ON when the integrated monitoring database is disabled, the repeated event monitoring function is disabled.

`-dd {ON | OFF}`

Specifies whether to start the Intelligent Integrated Management Base.

- ON: Starts the Intelligent Integrated Management Base when JP1/IM - Manager starts.
- OFF: Does not start the Intelligent Integrated Management Base when JP1/IM - Manager starts. The default is OFF.

If you specify ON, you must set up the integrated monitoring database in advance. You also must enable the event-source-host mapping.

If JP1/IM - Manager is started when the integrated monitoring database is not set up, the event-source-host mapping is disabled, or the IM database service is not running, the Intelligent Integrated Management Base terminates abnormally and outputs messages to the integrated trace log.

## Return values

|      |                                                          |
|------|----------------------------------------------------------|
| 0    | Normal termination                                       |
| 1    | Abnormal termination                                     |
| 7    | Execution permission error (Windows only)                |
| 111  | Failed to connect to the Event Base Service (in UNIX)    |
| -401 | Failed to connect to the Event Base Service (in Windows) |

## When definition enabled

Y: Enabled

--: Not applicable

#

The JP1/IM - View instance being connected must be restarted.

# jcomonitorfcheck

---

## Function

This command checks the definition file for opening monitor windows.

When this command is executed, it checks a specified definition file for opening monitor windows for any definition errors and then outputs the analysis results to standard output. Error information, such as definition errors, is output to standard error.

An analysis result is output for each event ID in the following format:

*product-name, event-ID*

*start-version, end-version*

*[subkey-name, attribute-name-used-as-key*

*[attribute-value-used-as-key, interface-name] ]*

*[interface-name, application-execution-definition-identifier,*

*command-argument, replacement-event-attribute]*

If there is only one version specification, such as 0600, the same value is output for both the start version and the end version. Similarly, if ALL is specified, ALL is displayed for both the start version and the end version.

If SUBKEY is set in the DEF\_KEY key definition, the contents of the subkey are displayed. SUBKEY is duplicated if it is also used in another DEF\_KEY key definition.

This command does not check whether the application execution definition identifier is defined in the definition file for executing applications.

## Format

```
jcomonitorfcheck monitor-window-opening-definition-directory-name
```

## Execution permission

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In UNIX: None

## Storage directory

In Windows:

*Console-path\bin\*

In UNIX:

*/opt/jplcons/bin/*

## Arguments

### *monitor-window-opening-definition-directory-name*

Specifies the name of the monitor window opening definition directory, expressed as an absolute path or a path relative to the current directory.

## Example

Execute the command for the following definition file:

```
DESC_VERSION=0300
# Monitor window transition definition file for AJS-View
DEF_KEY PRODUCT_NAME=/HITACHI/JP1/AJS2 EVENT_ID=00004102 INTERFACE=AJS2_MONITOR

## jcothreaddmp (Windows only)

---

### Function

This command outputs a thread dump in the event of a JP1/IM - View failure.

A thread dump output by the `jcothreaddmp` command is stored in the following folder:

*View-path*\log\

You can use the data collection tool to collect other failure data in addition to the output thread dump.

### Format

```
jcothreaddmp process-ID
```

### Execution permission

None

### Storage directory

*View-path*\bin\

### Arguments

*process-ID*

Specifies the process ID of the `java.exe` process of the disabled JP1/IM - View. You can specify only one process ID. It is not permissible to omit the process ID or to specify multiple process IDs.

If you are running multiple instances of JP1/IM - View, you must determine the process ID of the JP1/IM - View that can no longer be controlled by the Windows Task Manager.

In Windows Task Manager, JP1/IM - View is displayed as `java.exe`. If another java program is running at the same time, that program is also displayed as `java.exe`, making it difficult to distinguish between the programs. For details about how to identify the process ID of JP1/IM - View, see *12.4.1(1)(b) Outputting a thread dump for JP1/IM* in the *JP1/Integrated Management 3 - Manager Administration Guide*.

### Notes

- If the `jcothreaddmp` command is executed on a JP1/IM - View that is running normally, operation of JP1/IM - View may become unstable. In such a case, restart JP1/IM - View.

### Return values

|    |                                               |
|----|-----------------------------------------------|
| 0  | Normal termination                            |
| 1  | Option analysis error                         |
| 2  | Process checking error                        |
| 3  | Thread dump output request transmission error |
| 10 | Other error                                   |

# jcovcfsetup (Windows only)

## Function

This command registers into or deletes from the Windows **Start** menu the menu item for starting IM Configuration Management - View. Note that when IM Configuration Management - View is installed, it is not registered into the Windows **Start** menu.

This command works only when executed in the command prompt invoked from **Run as Administrator**.

## Format

```
jcovcfsetup [-i | -u]
```

## Execution permission

Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

## Storage directory

*View-path\bin\*

## Arguments

If no options are specified, the command executes in the same manner as when the `-i` option is specified.

- `-i`  
Specifies that the menu for starting IM Configuration Management - View is to be registered into the Windows **Start** menu.
- `-u`  
Specifies that the menu for starting IM Configuration Management - View is to be removed from the Windows **Start** menu.  
Note that if you have manually changed the menu name or its storage location, the command cannot remove the menu. In such a case, you must remove the menu manually.

## Notes

The maximum length of the command arguments (in bytes) depends on the OS. Specify the command arguments within the limitation of the applicable OS.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Example 1

Add **Configuration Management** to the menu of JP1/IM - View:

```
jcovcfsetup or jcovcfsetup -i
```

## Example 2

Remove **Configuration Management** from the menu of JP1/IM - View:

```
jcovcfsetup -u
```

# jcoview (Windows only)

---

## Function

This command opens a JP1/IM - View window.

The window to be opened depends on the option specifications, as shown below:

- Starting the Login window for JP1/IM - View  
When any option other than `-p` or `-e` is specified or no option is specified, the Login window opens.  
`-c` option is specified: The **Central Console** check box is selected in the Login window.  
`-s` option is specified: The **Central Scope** check box is selected in the Login window.  
`-h` option is specified: A value is entered in **Host to connect** in the Login window.  
`-u` option is specified: A value is entered in **User name** in the Login window.
- Opening the Event Console window and the Monitoring Tree window of JP1/IM - View  
When the `-h`, `-u`, or `-p` option is specified, the Event Console window and the Monitoring Tree window open. To open the Event Console window and the Monitoring Tree window, you must specify the `-h`, `-u`, or `-p` option.  
`-c` option is specified: The Event Console window opens.  
`-s` option is specified: The Monitoring Tree window opens.  
Neither the `-c` nor the `-s` option is specified: The Event Console window opens.
- Opening the Monitoring Tree (Editing) window of JP1/IM - View  
When the `-e` option is specified, the Monitoring Tree (Editing) window opens.

## Format

```
jcoview [[[-c] [-s]]  
        [-h connection-target-host-name] [-u user-name] [-p password]  
        | -e]
```

## Execution permission

None

## Storage directory

*View-path*\bin\

## Arguments

`-c`

Specifies that the Event Console window is to open.

If the password (`-p` option) is omitted, the Login window opens with the **Central Console** check box selected. This option cannot be specified together with the `-e` option.

This option is optional.

If the `-h`, `-u`, and `-p` options are specified and none of the `-c`, `-s`, and `-e` options is specified, the command assumes that the `-c` option is specified.

`-s`

Specifies that the Monitoring Tree window is to open.

If the password (`-p` option) is omitted, the Login window opens with the **Central Scope** check box selected. This option cannot be specified together with the `-e` option.

This option is optional.

`-h connection-target-host-name`

Specifies the name of the connection-target host. For the host name, from 1 to 255 bytes of characters are permitted. You can specify only a host where JP1/IM - Manager is running.

For the connection-target host name, you can specify the following:

- Host name defined on the host where the command is used
- Host name whose address can be resolved on the host where the command is used
- IP address

Only addresses in IPv4 address format can be specified. Addresses in IPv6 address format cannot be specified.

This option is optional, but if you specify the `-p` option, you must also specify this option.

`-u user-name`

Specifies the name of a JP1 user that has been registered in the authentication server. For the JP1 user name, from 1 to 31 alphanumeric characters are permitted (for alphabetic characters, only lowercase letters are permitted).

This option is optional, but if you specify the `-p` option, you must also specify this option.

`-p password`

Specifies the specified user's password. For the password, from 6 to 32 alphanumeric characters are permitted. Alphabetic characters are case sensitive.

If you specify this option, you must also specify the `-h` and `-u` options.

This option is optional.

`-e`

Specifies that the Monitoring Tree (Editing) window is to open.

When you specify this option, you must not specify any other options.

This option is optional.

## Important

- If you attempt to start JP1/IM - View by executing the `jcoview` command with an incorrect argument specified, the login window appears after either of the following messages is output:
  - KAVB0104-E Failed to authenticate the user.
  - KAVB1210-E A communication error occurred while establishing a connection.

Cannot convert the host name into an IP address. Confirm the host name.

Host name: <host-name>, Port number: <port-number>

Details: <detail-information>

In the login window displayed in this status, you may be unable to select the input fields even with the mouse to enter information in them. If this problem occurs, click the taskbar button for a program other than JP1/IM - View, and then click the login window.

- If the program `jcoview.exe` is executed from a command prompt where the code page is set to a value other than 932, the characters displayed on the screen might be garbled.
- If the program `jcoview.exe` is executed from a command prompt where the code page is set to a value other than 936, the characters displayed on the screen might be garbled.

## Return values

|     |                               |
|-----|-------------------------------|
| 0   | Normal termination            |
| 1   | Argument error                |
| 2   | Insufficient memory           |
| 3   | Resource acquisition failed   |
| 4   | Error message creation failed |
| 255 | System error                  |

### Example 1

Start JP1/IM - View and open the Login window:

```
jcoview
```

### Example 2

Start JP1/IM - View and display the Login window with `host` set in **Host to connect** and `jpladmin` set in **User name**:

```
jcoview -h host -u jpladmin
```

### Example 3

Start JP1/IM - View, log in by specifying `jpladmin` as the user name, `jpladmin` as the password, and `host` as the connection-target host, and then open the Event Console window:

```
jcoview -h host -u jpladmin -p jpladmin
```

### Example 4

Start JP1/IM - View, log in by specifying `jpladmin` as the user name, `jpladmin` as the password, and `host` as the connection-target host, and then open the Monitoring Tree window:

```
jcoview -s -h host -u jpladmin -p jpladmin
```

### Example 5

Start JP1/IM - View, log in by specifying `jpladmin` as the user name, `jpladmin` as the password, and `host` as the connection-target host, and then open the Event Console window and the Monitoring Tree window:

```
jcoview -c -s -h host -u jpladmin -p jpladmin
```

### Example 6

Start JP1/IM - View and open the Monitoring Tree (Editing) window:

```
jcoview -e
```

## Example 7

You can create a command shortcut, such as for Examples 2 and 3, for each host and each user.

# jcoview\_log.bat (Windows only)

## Function

This command is a tool for collecting data in the event of a JP1/IM - View failure. The data collected by this tool includes JP1/IM - View maintenance data, OS system information, and integrated trace logs. If JP1/IM - Manager and JP1/Base are installed on the same machine, data from JP1/IM - Manager and JP1/Base is also collected.

This tool constitutes a batch file, which cannot be customized by the user.

When you execute this tool, the target folders or files used for data collection are classified into primary and secondary data categories and the collected data is stored directly under a specified data storage folder.

The primary data, which consists of a minimum amount of logs and settings files, is collected for purposes such as identifying failures and investigating minor errors. The secondary data consists of the Windows event log, and provides the detailed information needed to investigate failures in depth.

If you execute `jcoview_log.bat` during a thread dump of JP1/IM - View, the tool displays the KAVB8946-I message asking whether the thread dump is to be deleted. If you enter `y`, the tool deletes the thread dump.

If necessary, compress the collected data by using a program such as a compression tool.

For details about the data that can be collected by this tool, see *12.3 Data that needs to be collected when a problem occurs* in the *JP1/Integrated Management 3 - Manager Administration Guide*.

The following tables show the organization of the folders directly under the data storage folder and the details of the data that is stored.

Table 1–37: Organization of the internal folders for the primary data

| Folder name                                                         | Stored data                                     |
|---------------------------------------------------------------------|-------------------------------------------------|
| <code>data-storage-folder\jp1_default\imm_1st\coview</code>         | JP1/IM - View patch information                 |
| <code>data-storage-folder\jp1_default\imm_1st\coview\conf</code>    | JP1/IM - View settings and definition files     |
| <code>data-storage-folder\jp1_default\imm_1st\coview\default</code> | Common definition information for JP1/IM - View |
| <code>data-storage-folder\jp1_default\imm_1st\coview\log</code>     | Log files for JP1/IM - View                     |
| <code>data-storage-folder\jp1_default\imm_1st\oslog</code>          | OS log information                              |
| <code>data-storage-folder\jp1_default\imm_1st\spool</code>          | Integrated trace logs (32-bit)                  |
| <code>data-storage-folder\jp1_default\imm_1st\spoolx64</code>       | Integrated trace logs (64-bit)                  |

Table 1–38: Organization of the internal folders for the secondary data

| Folder name                                                | Stored data       |
|------------------------------------------------------------|-------------------|
| <code>data-storage-folder\jp1_default\imm_2nd\oslog</code> | Windows event log |

## Format

```
jcoview_log.bat -f data-storage-folder  
                [-t]  
                [-q]
```

## Execution permission

Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

## Storage directory

*View-path*\tools\

## Arguments

*-f data-storage-folder*

Specifies the name of the folder to which the collected data is to be output, expressed as a full path or a path relative to the location where the command is executed. If the path contains a space, enclose the entire path in double-quotation marks ("). This option is mandatory.

If a nonexistent folder is specified, a new folder with that name is created. If an existing folder is specified, the contents of that folder are deleted and then the specified folder is created.

*-t*

Specifies that the `hosts` and `services` files are not to be collected.

*-q*

Specifies that the command is to be executed without requesting confirmation from the user.

## Notes

- If you wish to collect JP1/IM - View data at the same host as for JP1/IM - Manager, use the `jim_log.bat` command.
- Do not execute this tool more than once. If it is executed multiple times, collected data may be overwritten or data collection may fail.
- If a file to be collected cannot be found, the tool may display a message such as `The file was not found;` however, no action is necessary.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 8 | Abnormal termination |

## Example

Collect data in the `F:\tmp\bat` folder:

```
jcoview_log.bat -f F:\tmp\bat
```

The output results are as follows:

```

KAVB8925-I The directory does not exist. ("F:\tmp\bat")
           The directory will be created.
Press any key to continue...
KAVB8925-I The directory does not exist. ("F:\tmp\bat\jpl_default\imm_1st")
           The directory will be created.
Press any key to continue...
KAVB8925-I The directory does not exist. ("F:\tmp\bat\jpl_default\imm_2nd")
           The directory will be created.
Press any key to continue...
KAVB8926-I Data acquisition processing will start.
KAVB8927-I Execution of the "D:\Program Files\Hitachi\JP1IMM\bin\jimGetConfI
nfo.exe" command will start.
KAVB8921-I The information for JP1/IM - View will be acquired.
KAVB8922-I The information for JP1/IM - View has been acquired.
KAVB8928-I "D:\Program Files\Hitachi\JP1IMM\bin\jimGetConfInfo.exe" executio
n is ended. (ERRORLEVEL=0)
KAVB8929-I The system information will be acquired. Please wait.
KAVB8927-I Execution of the "D:\Program Files\Hitachi\JP1IMM\bin\jimGetMsInf
o.exe" command will start.
KAVB8928-I "D:\Program Files\Hitachi\JP1IMM\bin\jimGetMsInfo.exe" execution
is ended. (ERRORLEVEL=0)
KAVB8922-I The system information has been acquired.
KAVB8929-I "Watson log and crash dump" will be acquired. Please wait.
KAVB8927-I Execution of the "D:\Program Files\Hitachi\JP1IMM\bin\jimGetWtsnI
nfo.exe" command will start.
KAVB8928-I "D:\Program Files\Hitachi\JP1IMM\bin\jimGetWtsnInfo.exe" executio
n is ended. (ERRORLEVEL=0)
KAVB8922-I "Watson log and crash dump" has been acquired.
KAVB8921-I Windows Eventlog(Application) will be acquired.
KAVB8927-I Execution of the "D:\Program Files\Hitachi\JP1IMM\bin\jimGetEvLog
.exe" command will start.
KAVB8928-I "D:\Program Files\Hitachi\JP1IMM\bin\jimGetEvLog.exe" execution i
s ended. (ERRORLEVEL=0)
KAVB8922-I Windows Eventlog(Application) has been acquired.
KAVB8921-I Windows Eventlog(System) will be acquired.
KAVB8927-I Execution of the "D:\Program Files\Hitachi\JP1IMM\bin\jimGetEvLog
.exe" command will start.
KAVB8928-I "D:\Program Files\Hitachi\JP1IMM\bin\jimGetEvLog.exe" execution i
s ended. (ERRORLEVEL=0)
KAVB8922-I Windows Eventlog(System) has been acquired.
KAVB8921-I The setup.ini of JP1/IM - Manager will be acquired.
KAVB8922-I The setup.ini of JP1/IM - Manager has been acquired.
KAVB8921-I The setup.ilg of JP1/IM - Manager will be acquired.
KAVB8922-I The setup.ilg of JP1/IM - Manager has been acquired.
KAVB8921-I The setup.ini of JP1/Base will be acquired.
KAVB8922-I The setup.ini of JP1/Base has been acquired.
KAVB8921-I The setup.ilg of JP1/Base will be acquired.
KAVB8922-I The setup.ilg of JP1/Base has been acquired.
KAVB8921-I The setup.ini of JP1/IM - View will be acquired.
KAVB8922-I The setup.ini of JP1/IM - View has been acquired.
KAVB8921-I The setup.ilg of JP1/IM - View will be acquired.
KAVB8922-I The setup.ilg of JP1/IM - View has been acquired.
KAVB8921-I The integrated trace log will be acquired.
KAVB8922-I The integrated trace log has been acquired.
KAVB8921-I The integrated installer log will be acquired.
KAVB8922-I The integrated installer log has been acquired.
KAVB8921-I The installer log file will be acquired.

```

```
KAVB8922-I The installer log has been acquired.  
KAVB8921-I The hosts will be acquired.  
KAVB8922-I The hosts has been acquired.  
KAVB8921-I The services will be acquired.  
KAVB8922-I The services has been acquired.  
KAVB8921-I The registry information will be acquired.  
KAVB8922-I The registry information has been acquired.

KAVB8922-I The netstat information has been acquired.  
KAVB8921-I The ipconfig information will be acquired.  
KAVB8922-I The ipconfig information has been acquired.  
KAVB8921-I The net start information will be acquired.  
KAVB8922-I The net start information has been acquired.  
KAVB8921-I The set information will be acquired.  
KAVB8922-I The set information has been acquired.  
KAVB8918-I The data was successfully acquired.
```

## Function

This command changes the status of monitoring nodes (monitoring objects or monitoring groups). It also clears the logs of status change events at the monitoring nodes. It cannot change the monitoring status of monitoring nodes.

You can include this command in batch processing in order to automatically initialize the status of monitoring nodes as the last processing step of error recovery, or you can use this command to automatically initialize the status of monitoring nodes after eliminating the cause of an error by linking with the help desk system.

You can use this command when the Central Scope functions are enabled.

If you execute this command while JP1/IM - Manager (Central Scope) is already processing 32 or more command requests, communication is lost at the server end, which causes this command to fail.

## Format

```
jcschstat [-h logical-host-name]  
          -n monitoring-node-ID-1, monitoring-node-ID-2, monitoring-node-ID  
          -3...  
          [-s status-value]  
          [-i]  
          [-t timeout-period]  
          [-d]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Scope-path*\bin\

In UNIX:

/opt/jp1scope/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-n *monitoring-node-ID-1, monitoring-node-ID-2, monitoring-node-ID-3 . . .*

Specifies the IDs of the monitoring nodes (monitoring object IDs or monitoring group IDs) whose status is to be changed, expressed in hexadecimal notation.

You can specify a maximum of 10 monitoring node IDs. When you specify multiple IDs, separate them with the comma (,). The monitoring nodes are processed in the order in which they are specified.

**-s *status-value***

Specifies the new status for the specified monitoring nodes. The status value is case sensitive. For monitoring objects, you can specify `Emergency`, `Alert`, `Critical`, `Error`, `Warning`, `Normal`, `Debug`, or `Initial`. For monitoring groups, you can specify only `Initial`.

When the status of a specified monitoring node changes, the status is propagated to the higher nodes and the lower nodes are initialized.

If this option is omitted, `Initial` is assumed.

**-i**

Specifies that a confirmation message is to be displayed when the status of a monitoring node is to be changed.

**-t *timeout-period***

Specifies a timeout period for communication with the server. The permitted value is from 1 to 32,767 (seconds). The default is 1,800 seconds (30 minutes).

**-d**

Specifies that command processing is to be canceled and the command is to be terminated with an error if a monitoring node specified in the `-n` option does not exist or if a monitoring node status change fails.

If this option is omitted, the command skips processing on any monitoring node that does not exist or on which status change processing fails, and then processes the next monitoring node.

## Return values

|    |                                                                                                                                                   |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | Normal termination                                                                                                                                |
| 1  | Logical host name was not found                                                                                                                   |
| 2  | Argument error                                                                                                                                    |
| 4  | No permission to execute the command                                                                                                              |
| 12 | Insufficient memory                                                                                                                               |
| 32 | Data access error                                                                                                                                 |
| 33 | Specified monitoring tree ID or monitoring node ID was not found in the database                                                                  |
| 37 | No response from the server (connection establishment request failed)                                                                             |
| 38 | Communication with the server failed (the server was terminated during communication or the server's connection count exceeded the maximum value) |
| 39 | A timeout occurred (after a request was sent to the server, the timeout period was exceeded before a response was received)                       |
| 40 | An invalid response was sent from the server                                                                                                      |
| 42 | Another command or request is being processed                                                                                                     |
| 43 | A monitoring node for which not monitor is set is specified in <code>-n</code>                                                                    |
| 44 | A monitoring group is specified in <code>-n</code>                                                                                                |
| 99 | Other error                                                                                                                                       |

## Example

Change the status of monitoring node ID 8 to `Error`:

```
jcschstat -n 8 -s Error
```

## Example output

```
jcschstat -n 5 -s Normal  
KAVB7630-I The status of the monitoring node (5) has been set to Normal.
```

## Function

This command acquires monitoring object database storage information and outputs it locally to a file as a configuration file for monitoring tree. The information that is output to the file includes monitoring tree configuration information, common event monitoring conditions, and Visual Monitoring window configuration information.

You can use this command to store multiple generations of storage information in the monitoring object database. To copy the storage information in the monitoring object database to another server, execute this command and then use the `jcsdbimport` command to copy the storage information to the monitoring object database of the other server.

You can use this command when the Central Scope functions are enabled.

If you execute this command while updating data for Central Scope Service, the command terminates with an error. For example, if you execute this command while updating the server's tree from the Monitoring Tree (Editing) window or while changing the status of a monitoring node with the `jcschstat` command, the command terminates with an error.

A configuration file for monitoring tree that was output by JP1/IM - Manager version 08-10 or later cannot be imported by JP1/IM - Manager version 08-01 or earlier.

## Format

```
jcsdbexport [-h logical-host-name]  
            -o file-name  
            [-t timeout-period]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Scope-path*\bin\

In UNIX:

/opt/jp1scope/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-o *file-name*

Specifies the full path of the file to which tree configuration information is to be output. The file name must end with `.dat`. If the path contains a space, enclose the entire path in double-quotation marks (").

-t *timeout-period*

Specifies the timeout period for communication with the server. The permitted value is from 10 to 32,767 (seconds). The default is 1,800 seconds (30 minutes).

## Return values

|    |                                                                                                                                                   |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | Normal termination                                                                                                                                |
| 1  | Logical host name was not found                                                                                                                   |
| 2  | Argument error                                                                                                                                    |
| 3  | Specified file is invalid                                                                                                                         |
| 4  | No permission to execute the command                                                                                                              |
| 6  | No permission to access the specified file                                                                                                        |
| 12 | Insufficient memory                                                                                                                               |
| 13 | Insufficient disk capacity                                                                                                                        |
| 31 | Database initialization failed at the server                                                                                                      |
| 32 | Database access failed at the server                                                                                                              |
| 33 | Specified monitoring tree ID or monitoring node ID was not found in the database                                                                  |
| 37 | No response from the server (connection establishment request failed)                                                                             |
| 38 | Communication with the server failed (the server was terminated during communication or the server's connection count exceeded the maximum value) |
| 39 | A timeout occurred (after a request was sent to the server, the timeout period was exceeded before a response was received)                       |
| 40 | An invalid response was sent from the server                                                                                                      |
| 42 | Another command or request is being processed                                                                                                     |
| 99 | Other error                                                                                                                                       |

## Example

Output monitoring object database storage information to c:\temp\output.dat:

```
jcsdbexport -o c:\temp\output.dat
```

## Example output

```
KAVB7670-I Exporting of the monitoring tree definition to the file c:\temp\output.dat was successful.
```

# jcsdbimport

---

## Function

This command applies monitoring object database storage information that was output by the `jcsdbexport` command (monitoring tree configuration information, common event monitoring conditions, and Visual Monitoring window configuration information) to the monitoring object database of JP1/IM - Manager.

Use this command together with the `jcsdbexport` command to migrate JP1/IM - Manager monitoring object database storage information to another server.

You can use this command when the Central Scope functions are enabled.

If you execute this command while updating data for Central Scope Service, the command terminates with an error. For example, if you execute this command while updating the server's tree from the Monitoring Tree (Editing) window or while changing the status of a monitoring node with the `jcschstat` command, the command terminates with an error.

## Format

```
jcsdbimport [-h logical-host-name]  
            -o file-name  
            [-t timeout-period]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Scope-path*\bin\

In UNIX:

/opt/jp1scope/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-o *file-name*

Specifies the full path of a file that was output by the `jcsdbexport` command and that is to be applied to the monitoring object database of JP1/IM - Manager. The file name must end with `.dat`. If the path contains a space, enclose the entire path in double-quotation marks (").

-t *timeout-period*

Specifies the timeout period for communication with the server. The permitted value is from 10 to 32,767 (seconds). The default is 1,800 seconds (30 minutes).

## Notes

Importing information with the `jcsdbimport` command initializes the status of the monitoring tree.

## Return values

|    |                                                                                                                                                   |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | Normal termination                                                                                                                                |
| 1  | Logical host name was not found                                                                                                                   |
| 2  | Argument error                                                                                                                                    |
| 3  | Specified file is invalid                                                                                                                         |
| 4  | No permission to execute the command                                                                                                              |
| 6  | No permission to access the specified file                                                                                                        |
| 12 | Insufficient memory                                                                                                                               |
| 31 | Database initialization failed at the server                                                                                                      |
| 32 | Database access failed at the server                                                                                                              |
| 34 | Format error in the configuration file for monitoring tree                                                                                        |
| 37 | No response from the server (connection establishment request failed)                                                                             |
| 38 | Communication with the server failed (the server was terminated during communication or the server's connection count exceeded the maximum value) |
| 39 | A timeout occurred (after a request was sent to the server, the timeout period was exceeded before a response was received)                       |
| 40 | Invalid response was sent from the server                                                                                                         |
| 41 | Specified input file was not found                                                                                                                |
| 42 | Another command or request is being processed                                                                                                     |
| 48 | The file is not compatible with the file version specified by the server                                                                          |
| 99 | Other error                                                                                                                                       |

## Example

Apply the file `input.dat` output by the `jcsdbexport` command to the monitoring object database of JP1/IM - Manager:

```
jcsdbimport -o input.dat
```

## Example output

```
KAVB7660-I Importing of the monitoring tree definition from the file input.d  
at was successful.
```

# jcsdbsetup

---

## Function

This command creates a new ISAM file for storing the monitoring object database. When you execute this command, the existing monitoring object database is deleted and a new monitoring object database is created.

You must terminate JP1/IM - Manager before you can create a monitoring object database.

Make sure that you execute this command if you use any Central Scope functions.

## Format

```
jcsdbsetup [-h logical-host-name]  
           [-f]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Scope-path*\bin\

In UNIX:

/opt/jp1scope/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

-f

You must specify this option when there is an existing monitoring object database (if this option is omitted in such a case, an error results). If there is no existing monitoring object database, you can omit this option.

When this option is specified and there is a monitoring object database, the command displays the confirmation message Database files are existed. Delete these files? [y/n]. Entering Y and then pressing the **Enter** key will cause the existing monitoring object database to be deleted and a new monitoring object database to be created. If there is no existing monitoring object database, the command will create a new monitoring object database without displaying the confirmation message.

## Return values

|   |                              |
|---|------------------------------|
| 0 | Normal termination           |
| 1 | Logical host name is invalid |

|    |                                       |
|----|---------------------------------------|
| 2  | Argument error                        |
| 4  | No permission to execute the command  |
| 10 | Setup has not been completed          |
| 12 | Insufficient memory                   |
| 13 | Insufficient disk capacity            |
| 20 | Database already exists               |
| 42 | Another command or request is running |
| 99 | Other error                           |

# jcshostsexport

---

## Function

This command acquires host information from the host information database. When this command is executed, it loads host information from the host information database and stores it in a specified host information file (if no host information file name is specified, the host information is output to standard output).

You can use this command when the Central Scope functions are enabled.

## Format

```
jcshostsexport [-h logical-host-name] > host-information-file-name
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Scope-path*\bin\

In UNIX:

/opt/jp1scope/bin/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

*host-information-file-name*

Specifies the name of the file in which the host information is to be stored.

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.

If you execute with standby host in UNIX / Linux, an unwanted directory named */shared-directory-name* is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- */shared-directory-name*/jp1scope
- */shared-directory-name*/jp1scope/log

Delete */shared-directory-name* directory and files under it. Delete these unwanted directory and files, they will never to be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|    |                                        |
|----|----------------------------------------|
| 0  | Normal termination                     |
| 1  | Logical host name is invalid           |
| 2  | Argument error                         |
| 4  | No permission to execute the command   |
| 10 | Setup has not been completed           |
| 11 | There is no host information database  |
| 12 | Insufficient memory                    |
| 14 | Host information database is corrupted |
| 15 | Message initialization failed          |
| 16 | Host information database is in use    |
| 99 | Other error                            |

# jcshostsimport

---

## Function

This command registers host information into and deletes host information from the host information database. You can apply the host information while JP1/IM - Manager is running by executing the `jco_spmc_reload` command after this command has executed. While JP1/IM - Manager is stopped, you can apply the host information by starting JP1/IM - Manager.

You can use this command when the Central Scope functions are enabled.

## Format

```
jcshostsimport { { -o | -r } host-information-file-name | -d}  
               [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Scope-path*\bin\

In UNIX:

/opt/jp1scope/bin/

## Arguments

`-r host-information-file-name`

Specifies the name of the file that contains the host information that is to be registered into the host information database. When the `-r` option is specified, the command deletes all host information from the existing host information database and then registers the specified host information into the database.

For details about the format of the host information file, see *Host information file (jcs\_hosts)* in *Chapter 2. Definition Files*.

`-o host-information-file-name`

Specifies the name of the file that contains the host information that is to be registered into the host information database. When the `-o` option is specified, the command adds to the host information database the host information contained in the host information file without deleting the existing host information from the database (if an identical IP address exists, the information for that host is overwritten).

For details about the format of the host information file, see *Host information file (jcs\_hosts)* in *Chapter 2. Definition Files*.

`-d`

Specifies that all the existing host information is to be completely deleted from the host information database.

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed.

## Notes

- Execute this command only on the active host. Make sure that the shared disk is mounted when the command executes.
- Do not execute this command on the standby host.

If you execute with standby host in UNIX / Linux, an unwanted directory named */shared-directory-name* is created under the root directory of standby host local disk, and further unwanted directory and Files are created under that directory as follows.

- */shared-directory-name/jp1scope*
- */shared-directory-name/jp1scope/log*

Delete */shared-directory-name* directory and files under it. Delete these unwanted directory and files, they will never to be used. To prevent from mistakenly deleting the directory from shared directory, make sure that shared disk is not mounted on standby host before deleting the directory.

## Return values

|    |                                                             |
|----|-------------------------------------------------------------|
| 0  | Normal termination                                          |
| 1  | Logical host name is invalid                                |
| 2  | Argument error                                              |
| 3  | File name is invalid                                        |
| 4  | No permission to execute the command                        |
| 5  | Syntax error in the specified host information file         |
| 6  | No permission to access the specified host information file |
| 10 | Setup has not been completed                                |
| 11 | There is no host information database                       |
| 12 | Insufficient memory                                         |
| 13 | Insufficient disk capacity                                  |
| 14 | Host information database is corrupted                      |
| 15 | Message initialization failed                               |
| 16 | Host information database is in use                         |
| 99 | Other error                                                 |

## jim\_log.bat (Windows only)

### Function

This is a tool for collecting data in the event of a failure in JP1/IM - Manager or JP1/IM - View. The data collected by this tool includes maintenance information for JP1/IM - Manager, JP1/IM - View, and JP1/Base, system information from the OS, and integrated trace logs.

This tool is a batch file, which cannot be customized by the user.

When you execute this tool, the target folders or files used for data collection are classified into primary and secondary data categories and the collected data is stored directly under the specified data storage folder.

The primary data is collected for such purposes as identifying a failure and investigating the causes of minor failures. It consists of the minimum amount of logs and settings files. The secondary data provides the detailed information needed for an in-depth investigation of a failure. It consists of such data as the Windows event log and the JP1/Base event database.

If you execute `jim_log.bat` while a thread dump of JP1/IM - Manager (Central Console) or JP1/IM - View is available, the tool displays the KAVB8946-I message asking whether you want to delete the thread dump. If you enter `y`, the tool deletes the thread dump.

If necessary, use a program such as a compression tool to compress the collected data.

For details about the data that can be collected by this tool, see *12.3 Data that needs to be collected when a problem occurs* in the *JP1/Integrated Management 3 - Manager Administration Guide*.

If you are using the intelligent integrated management database, you can also collect data about the intelligent integrated management database<sup>#</sup>.

#

The logs of the intelligent integrated management database itself are excluded from the collection of this tool. If the case corresponds to described in *12.3.1(1)(b) JP1 information* in the *JP1/Integrated Management 3 - Administration Guide*, collect the logs manually.

If you do not want to obtain maintenance information of the intelligent integrated management database, execute this tool with specifying `-i` option.

The following tables show the organization of folders directly under the data storage folder and the data that is stored.

Table 1–39: Organization of the internal folders for the primary data of the physical host

| Folder name                                                       | Stored data                                                                                                                         |
|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>data-storage-folder\jpl_default\imm_1st\imm</code>          | <ul style="list-style-type: none"><li>Data storage folder for JP1/IM - Manager</li><li>JP1/IM - Manager patch information</li></ul> |
| <code>data-storage-folder\jpl_default\imm_1st\imm\conf</code>     | JP1/IM - Manager settings and definition files                                                                                      |
| <code>data-storage-folder\jpl_default\imm_1st\imm\log</code>      | Log files for JP1/IM - Manager                                                                                                      |
| <code>data-storage-folder\jpl_default\imm_1st\cons</code>         | Data storage folder for JP1/IM - Manager (Central Console)                                                                          |
| <code>data-storage-folder\jpl_default\imm_1st\cons\conf</code>    | JP1/IM - Manager (Central Console) settings and definition files                                                                    |
| <code>data-storage-folder\jpl_default\imm_1st\cons\default</code> | Common definition information for JP1/IM - Manager (Central Console)                                                                |

| Folder name                                                                 | Stored data                                                                                                                          |

| <i>data-storage-folder\logical-host-name\imm_2nd\cons</i>                              | Data storage folder for the logical host of JP1/IM - Manager (Central Console)                                                                   |
| <i>data-storage-folder\logical-host-name\imm_2nd\cons\operation\evgen</i>              | Correlation event generation history file for the logical host of JP1/IM - Manager (Central Console)                                             |
| <i>data-storage-folder\logical-host-name\imm_2nd\cons\operation\comexclude</i>         | Common exclusion history file and common exclusion-conditions definition history file for the logical host of JP1/IM - Manager (Central Console) |
| <i>data-storage-folder\logical-host-name\imm_2nd\scope</i>                             | Data storage folder for the logical host of JP1/IM - Manager (Central Scope)                                                                     |
| <i>data-storage-folder\logical-host-name\imm_2nd\scope\database</i>                    | Database information for the logical host of JP1/IM - Manager (Central Scope)                                                                    |
| <i>data-storage-folder\logical-host-name\imm_2nd\base</i>                              | Data storage folder for the logical host of JP1/Base                                                                                             |
| <i>data-storage-folder\logical-host-name\imm_2nd\base\log\COMMAND</i>                  | Command execution log files for the logical host of JP1/Base                                                                                     |
| <i>data-storage-folder\logical-host-name\imm_2nd\base\event</i>                        | Event database for the logical host of JP1/Base                                                                                                  |
| <i>data-storage-folder\logical-host-name\imm_2nd\imcf\data\imcf</i>                    | Data files for IM Configuration Management                                                                                                       |
| <i>data-storage-folder\logical-host-name\imm_2nd\imdb\database\imdb\imdbbackup.dat</i> | Backup files of the IM database                                                                                                                  |
| <i>data-storage-folder\logical-host-name\imm_2nd\imdd\data\imdd</i>                    | Data files for the logical host of JP1/IM - Manager (Intelligent Integrated Management Base)                                                     |
| <i>data-storage-folder\logical-host-name\imm_2nd\imgndb\database\imgndb</i>            | Data files for the logical host of the intelligent integrated management database                                                                |

## Format

```
jim_log.bat -f data-storage-folder
             [-h logical-host-name]
             [-t]
             [-n]
             [-p]
             [-r]
             [-g]
             [-a]
             [-s]
             [-c]
```

```
[ -d ]  
[ -x ]  
[ -w ]  
[ -q ]  
[ -b ]  
[ -i ]
```

The `-a` option is used for linking with BJEX or JP1/AS. For details about the `-a` option, see *11.5.2 jim\_log.bat (Windows only)* in the *JP1/Integrated Management 3 - Manager Administration Guide*.

## Execution permission

Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

## Storage directory

*Manager-path*\tools\

## Arguments

`-f data-storage-folder`

Specifies the name of the folder to which the collected data is to be output, expressed as a full path or a path relative to the location where the command is executed. If the path contains a space, enclose the entire path in double-quotation marks ("). This option is mandatory.

If a nonexistent folder is specified, a new folder with the specified name is created. If an existing folder is specified, the contents of that existing folder are deleted and the specified folder is created.

`-h logical-host-name`

When you are operating in a cluster system, this option specifies a logical host name and that the command is to collect data for that logical host as well as for the physical host. If this option is omitted, the command collects data for the physical host only. If you are not using a cluster system, there is no need to specify this option.

Note that this command will not use the logical host name that is set in the `JP1_HOSTNAME` environment variable. Therefore, if you use this command in a cluster system, make sure that you specify the logical host name in this option.

`-t`

Specifies that the `hosts` and `services` files are not to be collected.

`-n`

Specifies that maintenance data for JP1/Base is not to be collected.

`-p`

Specifies that the event database for JP1/Base is not to be collected.

`-r`

Specifies that the command execution log files for JP1/Base are not to be collected.

`-g`

Specifies that the correlation event generation history file is not to be collected.

`-a`

Specifies that the file for accumulated response-waiting events is not to be collected.

`-s`

Specifies that maintenance data for JP1/IM - Manager (Central Scope) is not to be collected.

- c  
Specifies that maintenance data for IM Configuration Management is not to be collected.
- d  
Specifies that maintenance data for the IM database is not to be collected.  
This argument cannot be specified together with the -x option.
- x  
Specifies that IM database backup files are to be collected.  
This argument cannot be specified together with the -d option.  
The IM database backup files are not included in the maintenance data for the IM database that is collected by default. If the IM database service is not running, the maintenance data is not collected; in such a case, start the IM database service and then re-execute the data collection tool. The backup files can be collected even when JP1/IM - Manager is running.
- w  
Specifies that maintenance data for JP1/IM - View is not to be collected.
- q  
Specifies that the command is to be executed without requesting confirmation from the user.
- b  
Specifies that maintenance data for Intelligent Integrated Management Base is not to be collected.
- i  
Specifies that maintenance data for the intelligent integrated management database is not to be collected.

## Notes

- This tool might collect a large amount of data. Before you execute this tool, you need to estimate the amount of disk space required and then check the capacity available on your machine. For details, see *12.4 Collecting data* in the *JP1/Integrated Management 3 - Manager Administration Guide*.
- Do not execute this tool more than once.
- If a file to be collected is not found, the tool might display a message such as `The file was not found`. However, it is not necessary to take any action.
- When you start JP1/Base or JP1/IM - Manager, it might display a message such as `Sharing violation`. However, it is not necessary to take any action.
- When you run the tool to collect the data, it places a certain amount of load on the computer (on disk I/O and other resources).
- If you send data to the support service without using this tool or send it with some of it excluded, detailed investigation may not be possible.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 8 | Abnormal termination |

## Example 1

Collect data for the physical host and for logical host `hostA` into the `D:\temp` folder:

```
jim_log.bat -f D:\temp -h hostA
```

The output result is as follows:

```
KAVB8925-I The directory does not exist. ("D:\temp\jpl_default\imm_1st")
           The directory will be created.
Press any key to continue...
KAVB8925-I The directory does not exist. ("D:\temp\jpl_default\imm_2nd")
           The directory will be created.
Press any key to continue...
KAVB8925-I The directory does not exist. ("D:\temp\hostA\imm_1st")
           The directory will be created.
Press any key to continue...
KAVB8925-I The directory does not exist. ("D:\temp\hostA\imm_2nd")
           The directory will be created.
Press any key to continue...
KAVB8926-I Data acquisition processing will start.
KAVB8927-I Execution of the "D:\Program Files\Hitachi\JP1IMM\bin\jimGetConfI
nfo.exe" command will start.

## Example 2

Collect data for the physical host into the nonexistent folder D:\temp, but do not specify the existing logical host (hostA):

```
jim_log.bat -f D:\temp
```

The output result is as follows:

```
KAVB8925-I The directory does not exist. ("D:\temp")
           The directory will be created.
Press any key to continue...
```

KAVB8925-I The directory does not exist. ("D:\temp\jpl\_default\imm\_1st")  
The directory will be created.  
Press any key to continue...

KAVB8925-I The directory does not exist. ("D:\temp\jpl\_default\imm\_2nd")  
The directory will be created.  
Press any key to continue...

KAVB8926-I Data acquisition processing will start.

KAVB8927-I Execution of the "D:\Program Files\Hitachi\JP1IMM\bin\jimGetConfInfo.exe" command will start.

KAVB8921-I The information for JP1/IM - Manager will be acquired.

KAVB8921-I The physical host information will be acquired.

KAVB8922-I The physical host information has been acquired.

KAVB8922-I The information for JP1/IM - Manager has been acquired.

KAVB8921-I The information for JP1/IM - Central Console will be acquired.

KAVB8921-I The physical host information will be acquired.

KAVB8922-I The physical host information has been acquired.

KAVB8922-I The information for JP1/IM - Central Console has been acquired.

KAVB8921-I The information for JP1/IM - Central Scope will be acquired.

KAVB8921-I The physical host information will be acquired.

KAVB8922-I The set information has been acquired.
KAVB8918-I The data was successfully acquired.
KAVB8934-I The following logical host(s) exist on this machine:
hostA
To acquire information about a logical host, execute "jim_log.bat -f output
-directory-name -h logical-hostname".
Press any key to continue...
```

# jim\_log.sh (UNIX only)

## Function

This is a tool for collecting data in the event of a failure in JP1/IM - Manager. The data collected by this tool includes maintenance information for JP1/IM - Manager and JP1/Base, system information from the OS, and integrated trace logs.

This tool is a shell script, which cannot be customized by the user.

When you execute this tool, it classifies the target directories or files used for data collection into primary and secondary data categories, uses the `tar` command to archive the data directly under the specified data storage directory, and then uses the `compress` command to create compressed files.

The primary data is collected for such purposes as identifying a failure and investigating the causes of minor failures. It consists of the minimum amount of logs and settings files. The secondary data provides the detailed information needed for an in-depth investigation of a failure. It consists of such data as core analysis information and data from the JP1/Base event database.

In an environment where the output of core files of the `systemd-core dump` is enabled, from the list of core files held on the system when this tool is executed, regarding the core files output by the JP1/IM-M process, the core files in the `collection-target log file` directory are collected.

If you execute the `jim_log.sh` command while a core dump and a thread dump of JP1/IM - Manager (Central Console) are available, the tool displays the `KAVB8941-I` and `KAVB8942-I` messages asking whether you want to delete the core dump or the thread dump. If you enter `y` or `yes`, the tool deletes the core dump or thread dump.

For details about the data that can be collected by this tool, see *12.3 Data that needs to be collected when a problem occurs* in the *JP1/Integrated Management 3 - Manager Administration Guide*.

If you are using the intelligent integrated management database, you can also collect data about the intelligent integrated management database<sup>#</sup>.

#

The logs of the intelligent integrated management database itself are excluded from the collection of this tool. If the case corresponds to described in *12.3.1(2)(b) JP1 information* in the *JP1/Integrated Management 3 - Administration Guide*, collect the logs manually.

If you do not want to obtain maintenance information of the intelligent integrated management database, execute this tool with specifying `-i` option.

The following table lists and describes the compressed files containing the collected data.

Table 1–43: Compressed files containing the collected data

| File name                                                | Description                          |
|----------------------------------------------------------|--------------------------------------|
| <code>jpl_default_imm_1st.tar.Z</code>                   | Primary data for the physical host   |
| <code>jpl_default_imm_2nd.tar.Z</code>                   | Secondary data for the physical host |
| <code>logical-host-name_imm_1st.tar.Z<sup>#</sup></code> | Primary data for the logical host    |
| <code>logical-host-name_imm_2nd.tar.Z<sup>#</sup></code> | Secondary data for the logical host  |

<sup>#</sup>: Created only when a logical host was specified in the `-h` option.

The compressed files are stored in the data storage directory. The following tables show the organization of the internal directories for the compressed files.

**Table 1–44: Organization of the internal directories for the primary data of the physical host**

| Directory and file name          | Stored data                                                                                          |
|----------------------------------|------------------------------------------------------------------------------------------------------|
| ./etc/opt/jplbase                | Automated startup and stop scripts for JP1/Base                                                      |
| ./etc/opt/jplbase/conf           | JP1/Base settings and definition files                                                               |
| ./etc/opt/jplbase/default        | Common definition information for JP1/Base                                                           |
| ./etc/opt/jplcons                | Automated startup and stop scripts for JP1/IM - Manager (Central Console)                            |
| ./etc/opt/jplcons/conf           | JP1/IM - Manager (Central Console) settings and definition files                                     |
| ./etc/opt/jplcons/default        | Common definition information for JP1/IM - Manager (Central Console)                                 |
| ./etc/opt/jplimm/conf/tools      | JP1/IM - Manager settings and definition files                                                       |
| ./etc/opt/jplimm/conf/imcf       | IM Configuration Management settings and definition files                                            |
| ./etc/opt/jplimm/conf/imdb       | IM database settings and definition files                                                            |
| ./etc/opt/jplimm/conf/imdd       | Settings and definition files for JP1/IM - Manager (Intelligent Integrated Management Base)          |
| ./etc/opt/jplimm/conf/imgndb     | Settings and definition files for the intelligent integrated management database                     |
| ./etc/opt/jplimm/plugin          | Plug - in for JP1/IM - Manager (Intelligent Integrated Management Base)                              |
| ./var/opt/jplimm/log/suggestion  | Response action execution history file for JP1/IM - Manager (Intelligent Integrated Management Base) |
| ./etc/opt/jplimm/default/imcf    | Common definition information for IM Configuration Management                                        |
| ./etc/opt/jplscope/conf          | JP1/IM - Manager (Central Scope) settings and definition files                                       |
| ./etc/opt/jplscope/default       | Common definition information for JP1/IM - Manager (Central Scope)                                   |
| ./opt/jpl/hcclibcnf              | Common definition information                                                                        |
| ./opt/jplbase                    | Patch application history and patch log information for JP1/Base                                     |
| ./opt/jplbase/conf               | Settings file for JP1/Base plug-in services                                                          |
| ./opt/jplimm                     | Patch application history and patch log information for JP1/IM - Manager                             |
| ./var/opt/jplbase/log            | Log files for JP1/Base                                                                               |
| ./var/opt/jplbase/sys/tmp        | Logs and temporary files for JP1/Base                                                                |
| ./var/opt/hitachi/HNTRLib2/spool | Integrated trace logs                                                                                |
| ./var/opt/jplcons/log            | Log files for JP1/IM - Manager (Central Console)                                                     |
| ./var/opt/jplimm/database/imdb   | Detailed log information for the IM database                                                         |
| ./var/opt/jplimm/log/imcf        | Log files for IM Configuration Management                                                            |
| ./var/opt/jplimm/log/imdb        | Log files for the IM database                                                                        |

| Directory and file name                        | Stored data                                                             |
|------------------------------------------------|-------------------------------------------------------------------------|

| <code>./var/opt/jplimm/log/_logical-host-name/oslog</code>        | OS log information                                                                                   |
| <code>./var/opt/jplimm/log/_logical-host-name/operationlog</code> | JP1/IM - Manager operation log                                                                       |
| <code>./shared-disk/jplimm/conf/imcf</code>                       | IM Configuration Management settings and definition files                                            |
| <code>./shared-disk/jplimm/conf/imdd</code>                       | Settings and definition files for JP1/IM - Manager (Intelligent Integrated Management Base)          |
| <code>./shared-disk/jplimm/conf/imgndb</code>                     | Settings and definition files for the intelligent integrated management database                     |
| <code>./var/opt/jplimm/database/imdb</code>                       | Detailed log information for the IM database                                                         |
| <code>./shared-disk/jplimm/log/imcf</code>                        | Log files for IM Configuration Management                                                            |
| <code>./shared-disk/jplimm/log/imdd</code>                        | Log files for JP1/IM - Manager (Intelligent Integrated Management Base)                              |
| <code>./shared-disk/jplimm/log/imgndb</code>                      | Log files for the intelligent integrated management database                                         |
| <code>./shared-disk/jplimm/log/suggestion</code>                  | Response action execution history file for JP1/IM - Manager (Intelligent Integrated Management Base) |
| <code>./var/opt/jplimm/log/imdb</code>                            | Log files for the IM database                                                                        |

**Table 1–47: Organization of the internal directories for the secondary data of the logical host**

| Directory and file name                                 | Stored data                                                                                                                                      |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>./shared-disk/event</code>                        | Event database for the logical host of JP1/Base                                                                                                  |
| <code>./shared-disk/jplbase/log/COMMAND</code>          | Command execution log files for the logical host of JP1/Base                                                                                     |
| <code>./shared-disk/jplcons/operation/evgen</code>      | Correlation event generation history files for the logical host of JP1/IM - Manager (Central Console)                                            |
| <code>./shared-disk/jplcons/operation/comexclude</code> | Common exclusion history file and common exclusion-conditions definition history file for the logical host of JP1/IM - Manager (Central Console) |
| <code>./shared-disk/jplscope/database</code>            | Database information for the logical host of JP1/IM - Manager (Central Scope)                                                                    |

| Directory and file name                                        | Stored data                                                              |
|----------------------------------------------------------------|--------------------------------------------------------------------------|
| <code>./var/opt/jplimm/log/_logical-host-name/oslog</code>     | OS log information                                                       |
| <code>./var/opt/jplimm/log/_logical-host-name/core</code>      | Core file                                                                |
| <code>./shared-disk/jplimm/data/imcf</code>                    | Data files for IM Configuration Management                               |
| <code>./shared-disk/jplimm/database/imdb/imdbbackup.dat</code> | Backup files of the IM database                                          |
| <code>./shared-disk/jplimm/data/imdd</code>                    | Data files for JP1/IM - Manager (Intelligent Integrated Management Base) |

## Format

```
jim_log.sh -f data-storage-directory
           [-h logical-host-name]
           [-t]
           [-u]
           [-n]
           [-p]
           [-r]
           [-g]
           [-a]
           [-s]
           [-c]
           [-d]
           [-x]
           [-q]
           [-b]
           [-i]
           [directory-name-or-file-name...]
```

The `-a` option is used for linking with BJEX or JP1/AS. For details about the `-a` option, see *11.5.3 jim\_log.sh (UNIX only)* in the *JP1/Integrated Management 3 - Manager Administration Guide*.

## Execution permission

Superuser permissions

## Storage directory

`/opt/jplimm/tools/`

## Arguments

`-f data-storage-directory`

Specifies the name of the directory or device to which the collected data is to be output, expressed as a full path or a path relative to the root directory. If you specify a directory name, the tool creates the files containing the collected data under that directory. If the path contains a space, enclose the entire path in double-quotation marks (`"`). This option is mandatory.

If a nonexistent directory is specified, a new directory with the specified name is created. If an existing directory is specified, that directory is deleted and the specified directory is created.

If a device name is specified, a write operation occurs on that device for each file that is created. If a device file name such as for a tape device is specified, the collected data is stored on the device without being compressed.

If you specify a device name and the `-q` option, the tool assumes that you have chosen `yes` for user confirmation. In such a case, you must set the device before you execute the command.

`-h` *logical-host-name*

When you are operating in a cluster system, this option specifies a logical host name and that the command is to collect data for that logical host as well as for the physical host. If this option is omitted, the command collects data for the physical host only. If you are not using a cluster system, there is no need to specify this option.

Note that this command will not use the logical host name that is set in the `JP1_HOSTNAME` environment variable. Therefore, if you use this command in a cluster system, make sure that you specify the logical host name in this option.

`-t`

Specifies that the `hosts`, `services`, and `passwd` files are not to be collected.

`-u`

Specifies that core analysis information is not to be collected. The core analysis information consists of a file obtained by using the `car` command of the Seraph tool to analyze a core dump file.

`-n`

Specifies that maintenance data for JP1/Base is not to be collected.

`-p`

Specifies that the event database for JP1/Base is not to be collected.

`-r`

Specifies that the command execution log files for JP1/Base are not to be collected.

`-g`

Specifies that the correlation event generation history file is not to be collected.

`-a`

Specifies that the file for accumulated response-waiting events is not to be collected.

`-s`

Specifies that maintenance data for JP1/IM - Manager (Central Scope) is not to be collected.

`-c`

Specifies that maintenance data for IM Configuration Management is not to be collected.

`-d`

Specifies that maintenance data for the IM database is not to be collected.

This argument cannot be specified together with the `-x` option.

`-x`

Specifies that IM database backup files are to be collected.

This argument cannot be specified together with the `-d` option.

The IM database backup files are not included in the maintenance data for the IM database that is collected by default. If the IM database service is not running, the maintenance data is not collected. In such a case, start the IM database service and then re-execute the data collection tool. The backup files can be collected even when JP1/IM - Manager is running.

`-q`

Specifies that the command is to be executed without requesting confirmation from the user.

`-b`

Specifies that maintenance data for Intelligent Integrated Management Base is not to be collected.

Specifies that maintenance data for the intelligent integrated management database is not to be collected.

#### *directory-name-or-file-name*

Specifies a file or directory to be collected by the data collection tool. Specify a full path name. To specify multiple names, use the space character to separate the names.

Note that this option must be the last option specified in the command. Specify it after you have specified all the other options that you need to specify. The collected data is stored as the primary data for the physical host.

## Notes

- This tool might collect a large amount of data. Before you execute this tool, you need to estimate the amount of disk space required and check the capacity available on your machine. For details, see *12.4 Collecting data* in the *JPI/Integrated Management 3 - Manager Administration Guide*.
- Do not execute this tool more than once. If it is executed multiple times, previously collected data might be overwritten or data collection might fail.
- When you run the tool to collect the data, it places a certain amount of load on the computer (on disk I/O and other resources).
- If you send data to the support service without using this tool or send it with some of it excluded, detailed investigation may not be possible.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 8 | Abnormal termination |

## Example 1

Collect data for the physical host and the logical host `hostA` into `/tmp/jpllog`:

```
jim_log.sh -f /tmp/jpllog -h hostA
```

The output result is as follows:

```
KAVB8925-I The directory does not exist. (/var/opt/jplimm/log/_jpl_default).
           The directory will be created.
KAVB8925-I The directory does not exist. (/var/opt/jplimm/log/_hostA).
           The directory will be created.
KAVB8926-I Data acquisition processing will start.
KAVB8921-I The physical host's first material will be acquired.
KAVB8922-I The physical host's first material has been acquired.
KAVB8921-I The physical host's second material will be acquired.
KAVB8922-I The physical host's second material has been acquired.
KAVB8921-I The logical host(hostA)'s first material will be acquired.
KAVB8922-I The logical host(hostA)'s first material has been acquired.
KAVB8921-I The logical host(hostA)'s second material will be acquired.
KAVB8922-I The logical host(hostA)'s second material has been acquired.
KAVB8918-I The data was successfully acquired.
```

## Example 2

Collect data for the physical host into the nonexistent directory /tmp/jpllog/, but do not specify the existing logical host (hostA):

```
jim_log.sh -f /tmp/jpllog
```

The output result is as follows:

```
KAVB8925-I The directory does not exist. (/tmp/jpllog).
           The directory will be created.
KAVB8925-I The directory does not exist. (/var/opt/jplimm/log/_jpl_default).
           The directory will be created.
KAVB8926-I Data acquisition processing will start.
KAVB8921-I The physical host's first material will be acquired.
KAVB8922-I The physical host's first material has been acquired.
KAVB8921-I The physical host's second material will be acquired.
KAVB8922-I The physical host's second material has been acquired.
KAVB8918-I The data was successfully acquired.
KAVB8935-I The following logical host(s) exist on this machine:
hostA
To acquire information about a logical host, execute "jim_log.sh -f output-d
irectory-name -h logical-hostname".
```

## Example 3

Collect data for the physical host into the /tmp/jpllog/ directory, which contains the jpl\_default\_imm\_1st.tar.Z and jpl\_default\_imm\_2nd.tar files, but do not specify the existing logical host (hostA):

```
jim_log.sh -f /tmp/jpllog
```

The output result is as follows (when y is entered for all responses):

```
KAVB8925-I The directory does not exist. (/var/opt/jplimm/log/_jpl_default).
           The directory will be created.
KAVB8926-I Data acquisition processing will start.
KAVB8921-I The physical host's first material will be acquired.
KAVB8922-I The physical host's first material has been acquired.
KAVB8921-I The physical host's second material will be acquired.
KAVB8944-I (/tmp/jpllog/jpl_default_imm_2nd.tar.Z) already exists. Do you wa
nt to overwrite it? [yes/no]y
KAVB8922-I The physical host's second material has been acquired.
KAVB8918-I The data was successfully acquired.
KAVB8944-I (/tmp/jpllog/jpl_default_imm_1st.tar.Z) already exists. Do you wa
nt to overwrite it? [yes/no]y
KAVB8935-I The following logical host(s) exist on this machine:
hostA
To acquire information about a logical host, execute "jim_log.sh -f output-d
irectory-name -h logical-hostname".
```

## Function

This tool is used to collect the documents (integrated agent host) required for fault investigation when a fault occurs in JP1/IM - Agent.

Collect the following documents related to JP1/IM - Agent:

- Documentation in *12.3.2 Data about JP1/IM - Agent* in the *JP1/Integrated Management 3 - Manager Administration Guide*
- JP1/IM agent control base documentation

For Windows, since the collected data is not compressed, compress it with a compressor, etc. as required.

For Linux, the collected material is compressed with tar and gzip commands.

- For Windows

The following table shows the folder structure and contents of the documents stored directly under the data storage folder.

**Table 1–48: Configuration of Collection Materials for the Data Collection Tool (Physical Host)**

| Folder name                                                | Stored data                                     |
|------------------------------------------------------------|-------------------------------------------------|
| <i>data-storage-folder\jpl_default\jplima</i>              | Product information                             |
| <i>data-storage-folder\jpl_default\syslog</i>              | System log information                          |
| <i>data-storage-folder\jpl_default\os</i>                  | OS data                                         |
| <i>data-storage-folder\jpl_default\communication</i>       | Communication status information                |
| <i>data-storage-folder\jpl_default\process</i>             | Process information                             |
| <i>data-storage-folder\jpl_default\scilence</i>            | Silence Configuration Info <sup>#</sup>         |
| <i>data-storage-folder\jpl_default\list</i>                | File list                                       |
| <i>data-storage-folder\jpl_default\inst</i>                | Installation documentation                      |
| <i>data-storage-folder\jpl_default\secret</i>              | Secret key information                          |
| <i>data-storage-folder\jpl_default\service</i>             | Service information                             |
| <i>data-storage-folder\jpl_default\jima_log_result.log</i> | Result of executing the data collection command |

#  
If the jpc\_alertmanager service is hesitation, silence configuration is not retrieved.

**Table 1–49: Configuration of Collection Material for the Data Collection Tool (Logical Host)**

| Folder name                                          | Stored data                             |
|------------------------------------------------------|-----------------------------------------|
| <i>data-storage-folder\logical-hostname\jplima</i>   | Product information                     |
| <i>data-storage-folder\logical hostname\scilence</i> | Silence Configuration Info <sup>#</sup> |
| <i>data-storage-folder\logical hostname\list</i>     | File list                               |
| <i>data-storage-folder\logical hostname\secret</i>   | Secret key information                  |

#

If the `jpc_alertmanager` service is hesitation, silence configuration is not retrieved.

Note that the following information is not collected by the data collection tool and must be collected manually.

| Data to be collected | Collection object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Product information  | <p>If you have already set up the log extraction command for SAP system, collect the following files manually:</p> <ul style="list-style-type: none"> <li>• Environment-parameter configuration file (any name.ini)</li> <li>• RFC library allocated when the log extraction command for SAP system was built</li> <li>• CRT library allocated when the log extraction command for SAP system was built</li> <li>• The following files-stored in the path set in WORKDIR of configuration file environment parameter <ul style="list-style-type: none"> <li>- Log file of SAP system log extraction command (any name)</li> <li>- SAP system log extraction command trace file (command name.log, command name.dat)</li> <li>- Trace file (dev_rfc*) output by RFC library</li> </ul> </li> </ul> <p>If the directory where the above files are stored is changed in the environment parameter configuration file or the argument when the log extraction command of SAP system is executed, the changed directory must also be collected.</p> <ul style="list-style-type: none"> <li>• <i>Destination when SAP system log extract command is installed\agtm folders</i></li> </ul> <p>If sensitive information such as passwords is included, delete the corresponding definition from the definition file after collection.</p> |

- For Linux

The following is a compressed file of the data stored directly under the *data-storage-directory*.

Table 1–50: Configuration of Collection Materials for the Data Collection Tool (Physical Host)

| Directory name                                | Stored data    |
|-----------------------------------------------|----------------|
| <i>data-storage-directory/jima_log.tar.gz</i> | Collected data |

Table 1–51: Configuration of Collection Material for the Data Collection Tool (Logical Host)

| Directory name                                         | Stored data    |
|--------------------------------------------------------|----------------|
| <i>data-storage-directory/logical host name.tar.gz</i> | Collected data |

Note that the following information is not collected by the data collection tool and must be collected manually.

| Data to be collected | Collection object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Product information  | <p>If you have already set up the log extraction command for SAP system, collect the following files manually:</p> <ul style="list-style-type: none"> <li>• Environment-parameter configuration file (any name.ini)</li> <li>• RFC library allocated when the log extraction command for SAP system was built</li> <li>• CRT library allocated when the log extraction command for SAP system was built</li> <li>• The following files-stored in the path set in WORKDIR of configuration file environment parameter <ul style="list-style-type: none"> <li>- Log file of SAP system log extraction command (any name)</li> <li>- SAP system log extraction command trace file (command name.log, command name.dat)</li> <li>- Trace file (dev_rfc*) output by RFC library</li> </ul> </li> </ul> <p>If the directory where the above files are stored is changed in the environment parameter configuration file or the argument when the log extraction command of SAP system is executed, the changed directory must also be collected.</p> <ul style="list-style-type: none"> <li>• <code>/opt/jplpc/agtm</code> directory</li> </ul> <p>If sensitive information such as passwords is included, delete the corresponding definition from the definition file after collection.</p> |

## Format

For Windows

```
jima_log.bat -f data-storage-folder
               [-l logical-host-environment-shared-folder]
               [-q]
```

For Linux

```
jima_log.sh -f data-storage-directory
               [-l logical-host-environment-shared-directory]
               [-q]
```

## Execution authority

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In Linux: Superuser permissions

## Storage destination directory

For Windows

*Agent-path*\tools\

For Linux

/opt/jplima/tools/

## Argument

*-f data-storage-directory*

For Windows

Specifies the name of the folder to which the collected data is to be output, expressed as a full path or a path relative to the location where the command is executed. If the path contains a space, enclose the entire path in double-quotation marks ("). This option is mandatory.

- A folder with the name "jp1\_default" is created under the specified folder, and the collected materials are stored. If necessary, compress the collected data with a compression tool.
- If jp1\_default folder already exists under the specified folder, ask whether to re-create the folder. When you re-create the folder, jp1\_default folder is deleted and then the folder is created. If you do not re-create it, the operation is aborted.
- If you specify a folder that does not exist, a new folder is created with that name.
- You cannot specify a path under JP1/IM - Agent installation folder, or under the shared-folder of the logical host environment.

For Linux

Specify the name of the directory to output the collected data in full path. This option is mandatory.

- A compressed file of the collected material is created under the name "jima\_log.tar.gz" in the specified directory.
- If a "jima\_log.tar.gz" or "jima\_log.tar" file already exists in the specified directory, ask whether to overwrite it. If you overwrite, the file is overwritten. If you do not overwrite it, the operation is aborted.

- If you specify a directory that does not exist, a new directory is created with that name.
- You cannot specify a device name.
- You cannot specify a path under JP1/IM - Agent installation directory, or under the shared-directory of the logical host environment.
- If the specified directory is one of the following, an error occurs.
  - Have no write permission
  - Fail to create a directory
  - A file with the same name as the specified directory exists

#### -l *logical-host-environment-shared-directory*

Specify the full path shared directory of the logical host environment to be collected when executing on the active host of the cluster system. Do not specify this option if executing on the standby host or not using a cluster system. When this option is specified, both the physical host documentation and integrated agent documentation in shared-directory for the specified logical host environment are collected. If you omit this option, integrated agent data in shared-directory for the specified logical host environment is not collected.

If a directory that does not exist is specified, an error results.

If the acquisition of the logical host name fails, some information is not collected.

#### -q

Specifies that the command is to be executed without user confirmation. For details about the user verification items to be omitted, refer to the explanation of "-f *data-storage-directory*".

## Notes

- Do not run this tool at the same time. Documents may be overwritten or may not be collected.
- There is a certain amount of overload (e.g., disc I/O) when running a tool to collect data. In addition, if a large number of Windows events are displayed, it may take longer to execute the command depending on the conditions.
- If you send the documentation to Support Services without using this tool, or if you exclude the documentation and send it, you may not be able to perform an accurate survey.

## Return value

|   |                      |
|---|----------------------|
| 0 | Normal completion    |
| 8 | Abnormal termination |

## Log Output

The log output destination is shown below.

For Windows

Log file "jima\_log\_result.log" to be stored in the folder specified in the *data-storage-directory*

For Linux

Log file "jima\_log\_result.log" included in the compressed file "jima\_log.tar.gz" stored in the directory specified in the *data-storage-directory*

## Examples of use

For Windows

```
jima_log.bat -f C:\tmp\jima
```

For Linux

```
jima_log.sh -f /tmp/jima -l /shdisk1/imagent -q
```

# jima\_log\_aix (AIX only)

## Function

This tool is used to collect documents (monitored AIX hosts) required for failure investigation when a failure occurs in JP1/IM - Agent.

Collect the following documents related to JP1/IM - Agent:

- Documentation in *12.3.2 Data about JP1/IM - Agent* in the *JP1/Integrated Management 3 - Manager Administration Guide*
- JP1/IM agent control base documentation

The collected documents are in a compressed format using tar and compress commands.

The following is a compressed file of the data stored directly under the data storage directory.

Table 1–52: Composition of Collection Materials for Collection Tools

| Directory name                                   | Stored data    |
|--------------------------------------------------|----------------|
| <i>data-storage-directory/jima_log_aix.tar.Z</i> | Collected data |

## Format

```
jima_log_aix.sh -f data-storage-directory
                  [-l Node-exporter-for-AIX-destination-directory]
                  [-q]
```

## Execution authority

Superuser permissions

## Storage destination directory

It is stored in the directory where Node exporter for AIX archived file (node\_exporter\_aix\_VVRRSS.tar) is extracted.

- When operating on a physical host

```
any-directory/node_exporter_aix/jplima/tools/
```

- When operating on a logical host

```
shared-directory/node_exporter_aix/jplima/tools/
```

## Argument

-f *data-storage-directory*

Specify the name of the directory to output the collected data in full path. This option is mandatory.

- A compressed file of the collected material is created under the name "jima\_log\_aix.tar.Z" in the specified directory.
- If a "jima\_log\_aix.tar.Z" or "jima\_log\_aix.tar" file already exists in the specified directory, ask whether to overwrite it. If you overwrite, the file is overwritten. If you do not overwrite it, the operation is aborted.

- If you specify a directory that does not exist, a new directory is created with that name.
- You cannot specify a device name.
- If the specified directory is one of the following, an error occurs.
  - Have no write permission
  - Fail to create a directory
  - A file with the same name as the specified directory exists

#### -l *Node-exporter-for-AIX-destination-directory*

To collect the file list, specify the directory where Node exporter for AIX is located in the full path or the path format relative to the location where this command was executed. If you specify a directory that does not exist, data collection is not performed and other processing continues.

#### -q

Specifies that the command is to be executed without user confirmation. For details about the user verification items to be omitted, refer to the explanation of "-f *data-storage-directory*."

## Notes

- Do not run this tool at the same time. Documents may be overwritten or may not be collected.
- There is a certain amount of overload (e.g., disc I/O) when running a tool to collect data. Also, depending on the conditions, such as log enlargement, it may take time to execute the command.
- If you send the documentation to Support Services without using this tool, or if you exclude the documentation and send it, you may not be able to perform an accurate survey.

## Return value

|   |                      |
|---|----------------------|
| 0 | Normal completion    |
| 8 | Abnormal termination |

## Log Output

The log output destination is shown below.

Log file "jima\_log\_result.log" included in the compressed file "jima\_log\_aix.tar.Z" stored in the directory specified in the *data-storage-directory*

## Examples of use

```
jima_log_aix.sh -f /tmp -l /aix -q
```

# jimalhsetup

---

## Function

This command sets up a new logical host of JP1/IM - Agent.

This command does not set up the following optional functions and data delivery function to multiple manager hosts.

- OracleDB exporter
- Node exporter for AIX
- SAP system monitoring
- SQL exporter

If you want to use these functions on a logical host, set up the system manually after using this command.

## Format

```
jimalhsetup -h logical-hostname
              -d shared-directory
              -c {online | standby}
              -f set-up-configuration-file
              [-q]
```

## Execution authority

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In Linux: Superuser permissions

## Storage destination directory

For Windows

*Agent-path*\tools\

For Linux

/opt/jplima/tools/

## Argument

-h *logical-hostname*

Specifies the logical host name of the target host to be set up.

-d *shared-directory*

Specifies the directory for the logical host to be created on the shared disk.

-c {online | standby}

Specifies the type of setup for the running system and the standby system in the cluster configuration.

- **online**: Specifies that the running system is to be set up.
- **standby**: Specifies that the standby system is to be set up.

To perform logical host operation in a non-clustered environment, specify "online" as-c option.

### **-f *set-up-configuration-file***

Specifies configuration file of the new setup command for a logical host that contains information such as:

- Host information of JP1/IM - Manager to connect to
- Proxy info for connecting to JP1/IM - Manager
- Enabling and disabling services

The path to the file can be either full or relative to the location where the command was executed.

If you are setting up in a clustered environment, use the same setup configuration file for the running system and the standby system.

For details about configuration file, see [Configuration file of the logical host new setup command \(any-file-name\)](#) in *Chapter 2. Definition Files*.

### **-q**

Specifies that the command argument and setup configuration file content are to be checked, and the setup command processing is to be started without user confirmation.

- If you specify the **-q** option: Does not prompt for confirmation in the console prior to starting the new setup process (this is the same as typing "y" and pressing **Enter** in all challenge messages).
- If you omit the **-q** option: Prompt the console for confirmation before starting the new setup process.

## **Return value**

|   |                      |
|---|----------------------|
| 0 | Normal completion    |
| 1 | Abnormal termination |

## **Log output**

- Output destination

- In Windows

*Agent-path*\logs\tools\

- In Linux

/opt/jplima/logs/tools/

## **Examples of use**

- For Windows

```
jimalhsetup -h LOGICALHOST01 -d c:\common\dir01 -c online -f c:\work\jpc_lhsetup.properties -q
```

- For Linux

```
jimalhsetup -h LOGICALHOST01 -d /common/dir01 -c online -f /work/jpc_lhsetup.properties -q
```

## **Notes**

- Do not run this command more than once at the same time. If the command is executed at the same time, the result may be incorrect even if the command terminates normally.
- Be sure to execute this command while all JP1/IM - Agent services are stopped. If it is executed while the service of JP1/IM - Agent is running, the file to be updated may be locked and file update may fail.

- Be sure to execute this command without opening the definition file in a text editor or the like. If you execute the command while editing the definition file with a text editor, etc., the file to be updated may be locked and file update may fail.
- If the file to be updated is locked by anti-virus software, etc., file update may fail. Make sure that the files to be updated are not subject to anti-virus software.
- If the setup process is started and then terminates with an error in the middle of execution, eliminate the cause of the error, perform the procedure shown in *Recovery procedure in the event of abnormal termination after the validation pass* below, and then re-execute the command to complete the setup process (make sure that all files have been updated).

#### - Recovery procedure in the event of abnormal termination after the validation pass

If the command ends abnormality after the KNBC10117-I message is output on the console, perform the recovery operation as follows:

##### • For Windows

1. Verify that the logical host service is registered in Windows.

At the command prompt, run `services.msc` to open management console and verify that the logical host service is registered. If it is not registered, step 2 does not need to be performed.

2. Deactivates the service for the logical host registered in Windows.

Release the service from Windows for the service to be used by the logical host.

To remove a logical host service, use the following command:

```
Agent-path\tools\jpc_service -off service-key -h logical-hostname
```

The following shows a sample procedure for deactivating Alertmanager service.

```
Agent-path\tools\jpc_service -off jpc_alertmanager -h logical hostname
```

3. Remove shared-folder.

##### • For Linux

1. Verify that the logical host service is registered in systemd.

Run `systemctl list-unit-files` command. Verify that the logical host service is registered. If it is not registered, steps 2 to 4 are not required.

2. Enable the service to unregister logical host service registered with systemd.

If there is a service on a logical host whose service status is masked, to remove the service for the logical host from systemd, run the following command to enable the service:

```
/opt/jplima/tools/jpc_service -on service-key -h logical-hostname
```

The following example shows how to enable Alertmanager service:

```
/opt/jplima/tools/jpc_service -on jpc_alertmanager -h logical-hostname
```

3. Remove unit definition file for the logical host.

Delete the unit definition file for the logical host under `/usr/lib/systemd/system`.

File name to be deleted: `jpc_service-name_logical-hostname.service`

#### 4. Refresh systemd.

Run the following command to refresh systemd:

```
# systemctl daemon-reload
```

#### 5. Remove shared-directory.

## Function

This command upgrades the logical host environment after installing JP1/IM - Agent version upgrade.

This command does not set up the following optional functions and data delivery function to multiple manager hosts.

- OracleDB exporter
- Node exporter for AIX
- SAP system monitoring
- SQL exporter

If you want to use these functions on a logical host, set up the system manually after using this command.

## Format

```
jimalhupdate VVRRSS
            -h logical-hostname
            -d shared-directory
            -c {online | standby}
            -f set-up-configuration-file
            [-q]
```

## Execution authority

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In Linux: Superuser permissions

## Storage destination directory

For Windows

*Agent-path*\tools\

For Linux

/opt/jplima/tools/

## Argument

*VVRRSS*

Specify the version prior to upgrading JP1/IM - Agent in VVRRSS format.

-h *logical-hostname*

Specifies the logical host name of the target host to be set up.

-d *shared-directory*

Specifies the directory for the logical host to be created on the shared disk.

-c {online | standby}

Specifies the type of setup for the running system and the standby system in the cluster configuration.

- **online**: Specifies that the running system is to be set up.

- **standby**: Specifies that the standby system is to be set up.

To perform logical host operation in a non-clustered environment, specify "online" as-c option.

#### **-f *set-up-configuration-file***

Specifies configuration file of the version upgrade setup command for the logical host that describes whether the service is enabled or disabled.

The path to the file can be either full or relative to the location where the command was executed.

If you are setting up in a clustered environment, use the same setup configuration file for the running system and the standby system.

For more information about configuration file, see [Configuration file of the logical host version upgrade setup command \(any-file-name\)](#) in *Chapter 2. Definition Files*.

#### **-q**

Specifies that the command argument and setup configuration file content are to be checked, and the setup command processing is to be started without user confirmation.

- -If you specify the q option: The console does not prompt for confirmation prior to starting the upgrade setup process. (This is the same as typing "y" and pressing **Enter** in all confirmation messages.)
- -If the q option is omitted: The console prompts for confirmation before starting the upgrade setup process.

## **Return value**

|   |                      |
|---|----------------------|
| 0 | Normal completion    |
| 1 | Abnormal termination |

## **Log output**

- Output destination

- In Windows

*Agent-path*\logs\tools\

- In Linux

/opt/jplima/logs/tools/

## **Examples of use**

- For Windows

```
jimalhupdate 131000 -h LOGICALHOST01 -d c:\common\dir01 -c online -f c:\work\jpc_lhupdate.properties -q
```

- For Linux

```
jimalhupdate 131000 -h LOGICALHOST01 -d /common/dir01 -c online -f /work/jpc_lhupdate.properties -q
```

## **Notes**

- Do not run this command more than once at the same time. If the command is executed at the same time, the result may be incorrect even if the command terminates normally.
- Be sure to execute this command while all JP1/IM - Agent services are stopped. If it is executed while the service of JP1/IM - Agent is running, the file to be updated may be locked and file update may fail.

- Be sure to execute this command without opening the definition file in a text editor or the like. If you execute the command while editing the definition file with a text editor, etc., the file to be updated may be locked and file update may fail.
- If the file to be updated is locked by anti-virus software, etc., file update may fail. Make sure that the files to be updated are not subject to anti-virus software.
- If the setup process is started and then terminates with an error in the middle of execution, eliminate the cause of the error, perform the procedure shown in *Recovery procedure in the event of abnormal termination after the validation pass* below, and then re-execute the command to complete the setup process (make sure that all files have been updated).
- This command cannot be executed in an environment where a new setup of the logical host has not been completed.

#### - Recovery procedure in the event of abnormal termination after the validation pass

If the command ends abnormality after the KNBC10117-I message is output on the console, perform the recovery operation as follows:

##### • For Windows

1. Check if the logical host service to be added to Windows is registered in the version upgrade.

At the command prompt, run `services.msc` to open management console and verify that the service for the logical host that you want to add is registered. If it is not registered, step 2 does not need to be performed.

The services to be added differ depending on the version prior to the version upgrade. For details, see [Configuration file of the logical host version upgrade setup command \(any-file-name\)](#) in Chapter 2. Definition Files.

2. Deactivates the service for the logical host registered in Windows.

Release the service from Windows for the service to be used by the logical host.

To remove a logical host service, use the following command:

```
Agent-path\tools\jpc_service -off service-key -h logical-hostname
```

The following shows a sample procedure for deactivating VMware exporter service.

```
Agent-path\tools\jpc_service -off jpc_vmware_exporter -h logical-hostname
```

##### • For Linux

1. Check whether the logical host service to be added to systemd is registered in the version upgrade.

Execute `systemctl list-unit-files` command. After the version upgrade, check whether the logical host service to be added is registered. If it is not registered, steps 2 to 4 are not required.

The services to be added differ depending on the version prior to the version upgrade. For details, see [Configuration file of the logical host version upgrade setup command \(any-file-name\)](#) in Chapter 2. Definition Files.

2. Enable the service to unregister logical host service registered with systemd.

If there is a service on a logical host whose service status is masked, to remove the service for the logical host from systemd, run the following command to enable the service:

```
/opt/jplima/tools/jpc_service -on service-key -h logical-hostname
```

The following example shows how to enable VMware exporter service:

```
/opt/jplima/tools/jpc_service -on jpc_vmware_exporter -h logical-hostname
```

3. Remove unit definition file for the logical host to be added in the version upgrade.

Delete the unit definition file for the logical host under `/usr/lib/systemd/system`.

File name to be deleted: `jpc_service-name_logical-hostname.service`

#### 4. Refresh systemd.

Run the following command to refresh systemd:

```
# systemctl daemon-reload
```

## Function

This command obfuscates the specified secret and add it to the secret management File. Added secret is read and used by JP1/IM - Agent service.

For details about the secrets that you can Setup with this command, see *3.15.10 Secret obfuscation function* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## Format

- To list the keys that added a secret:

```
jimasecret -list  
                [-l shared-directory]
```

- To add or update a secret specifying the key:

```
jimasecret -add  
                -key key-name  
                -s secret  
                [-l shared-directory]
```

- To delete the secret specifying the key:

```
jimasecret -rm  
                -key key-name  
                [-l shared-directory]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Agent-path\tools\*

In Linux:

*/opt/jplima/tools/*

## Arguments

**-list**

Lists the keys for the secret that you add. The secrets are not displayed.

It cannot be specified together with **-add**, or **-rm** option.

**-add**

Add a new secret by keying it.

If you specify a key that has already been added, overwrite the secret. At this time, overwriting is not checked.

You can Add up to 1,000 secrets.

If you specify this option, you must also specify `-key` and `-s` options.

Cannot be specified together with `-list` or `-rm` option.

`-rm`

Delete the secret that is already added by keying.

If a key that does not exist is specified, Error is returned.

If you specify this option, you must also specify `-key` option.

Cannot be specified together with `-list` or `-rm` option.

`-key` *key-name*

Specifies the *key-name* of the secret that you want to add, modify, or delete.

The characters that can be specified are 0x20 to 0x7e characters of ASCII.

The maximum length that can be specified is 1,024 characters.

The specific key format is shown below.

- Information about the manager of connection destination:

- Key for the proxy password to connect to the manager host:

```
immgr.proxy_user.authentication-ID
```

For the *authentication-ID*, specify the user ID specified in the `immgr.proxy_user` in the imagent common settings file (`jpc_imagentcommon.json`).

- The key of initial secret to connect to the manager host:

```
immgr.initial_secret
```

- The key of client secret to connect to the manager host:

```
immgr.client_secret
```

If you use data delivery function to multiple manager hosts, use the following keys instead of the above keys:

- Key for the proxy password to connect to the manager host

```
jmmgr.proxy_user-imagent-group-identifier.Authentication-ID
```

For the *authentication-ID*, specify the user ID specified in the `proxy_user` of the secondary element (the element whose `imagid` below `immgrs` array matches *imagent group-identifier*) in the imagent common configuration file (`jpc_imagentcommon.json`).

- Keying initial secret to connect to the manager host

```
immgr.initial_secret-imagent-group-identifier
```

- Keying client secret to connect to the manager host

```
immgr.client_secret-imagent-group-identifier
```

- JP1/IM agent control base

- The key for registration of password of the user used for Action Execution:

```
action.user.user-name
```

Set user name user that is set to `action.username` in imagent configuration file (`jpc_imagent.json`). This is only for Windows. In Linux, it is ignored even if it is specified.

### Important

Value specified in `-key` is not checked for correct format.

### Note

Specify client secret only if you want to manually delete it.

#### - For Blackbox exporter:

- Key to add password of the proxy authentication:

```
Blackbox.module-name.proxy_user.authentication-ID
```

For the *module-name*, specify the module name specified for Blackbox exporter configuration file (`jpc_blackbox_exporter.yml`).

For *authentication-ID*, specify the user ID specified for `proxy_user` in Blackbox exporter configuration file (`jpc_blackbox_exporter.yml`)

- Keys used to Add Password of the monitored Web Server:

```
Blackbox.module-name.basic_auth.authentication-ID
```

For the *module-name*, specify the module name specified for Blackbox exporter configuration file (`jpc_blackbox_exporter.yml`).

For *authentication-ID*, specify the user ID specified for `basic_auth.username` in Blackbox exporter configuration file (`jpc_blackbox_exporter.yml`)

- Key to add Bearer token of the monitored Web Server:

```
Blackbox.module-name.bearer_token
```

For the *module-name*, specify the module name specified for Blackbox exporter configuration file (`jpc_blackbox_exporter.yml`).

#### - For Primitor

- Keys used to add client secret of the Resource Discovery:

```
Promitor.resource_discovery.env.AUTH_APPKEY
```

- Key to add client secret key of the Scraper:

```
Promitor.scraper.env.AUTH_APPKEY
```

#### - For OracleDB exporter

There are two types of keys for registering a password for connecting to OracleDB:

- Password-key to connect to OracleDB (type of specifying the username)

```
OracleDB.user.user-name
```

For the *user-name*, specify the username that is set in the environment-variable `DATA_SOURCE_NAME`. Make sure to match the case.

- Password-key to connect to OracleDB (type of specifying the host name, listener service name, and username)

```
OracleDB.host.host-name.listener.listener-service-name.user.user-name
```

For the *host-name*, specify the hostname of OracleDB server for DATA\_SOURCE\_NAME. Make sure to match the case.

For the *listener-service-name*, specify the service name of the environment-variable DATA\_SOURCE\_NAME. Make sure to match the case.

For the *user-name*, specify the username that is set in the environment-variable DATA\_SOURCE\_NAME. Make sure to match the case.

Typically, you use the key which is the "type of specifying the username".

If more than one user with the same username exists and a different password is set, you must set a password for each OracleDB host/service using the "type of specifying the host name, listener service name, and username".

OracleDB exporter retrieves the values of the *host-name*, *listener-service-name*, and *user-name* from the values of the environment variable DATA\_SOURCE\_NAME. Search for a registered password by configuring the key in the "type of specifying the username" or the "type of specifying the host name, listener service name, and username". If the password could be retrieved in both formats, use the key "type of specifying the host name, listener service name, and username".

#### - For Web exporter

There are two types of keys for registering passwords for executing Web scenarios from Web exporter:

- Password key for executing Web scenarios (in the form of a username)

```
Webscena.user.user-name
```

The username specifies the user specified in Web exporter configuration file (jpc\_web\_exporter) username.

- Password key for executing Web scenarios (in the form of a username and domain name)

```
Webscena.user.user-name.domainname.domain-name
```

The username specifies the user specified in Web exporter configuration file (jpc\_web\_exporter) username.

For domain name, specify domain name specified in Web exporter configuration file (jpc\_web\_exporter) domainname.

If there is more than one user with the same username, use the key in the Format for specifying the username and domain name.

#### - For VMware exporter

- Section password key to connect to VMware ESXi

When using VMware exporter, be sure to specify "vmware.section.default" as the key. The first section name of the connection destination is "default" and the secret for "default" is mandatory.

```
Vmware.section.section-name
```

For the section name, specify the section name specified in VMware exporter configuration file (jpc\_vmware\_exporter.yml).

#### -s *secret*

Specifies the secret (Password) to be added or updated.

The characters that can be specified are 0x20 to 0x7e characters of ASCII.

The maximum length that can be specified is 1,024 characters.

#### -1 *shared-directory*

For a Logical host environment, specify Logical host shared directory.

Specify a relative or absolute path.

The length of the path can be up to 63 bytes.

Character types are not checked.

## Notes

- The Value specified in `-key` is not checked for correct format.
- When you run this command, if the secret (password) contains the subject characters listed in the following table, escaping is required.

| Target characters that require escaping | How to escape                                                                                                            | Escape example |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------|----------------|
| "                                       | Escaping is required in both Window and Linux environments.<br>Insert the escape character "\" before the target symbol. | \ "Password"   |
| ^                                       | Escaping is required in both Window and Linux environments.<br>Enclose the password in double quotation marks.           | " ^Password"   |
| <                                       |                                                                                                                          | " <Password"   |
| >                                       |                                                                                                                          | " >Password"   |
| &                                       |                                                                                                                          | " &Password"   |
|                                         |                                                                                                                          | "   Password"  |
| !                                       | Escaping is required only for Linux environments.<br>Insert the escape character "\" before the target symbol.           | \ !Password    |
| \$                                      |                                                                                                                          | \ \$Password   |
| \                                       |                                                                                                                          | \ \Password    |
| `                                       |                                                                                                                          | \ ` Password   |
| '                                       | Escaping is required only for Linux environments.<br>Enclose the password in double quotation marks.                     | " ' Password"  |
| (                                       |                                                                                                                          | " ( Password"  |
| )                                       |                                                                                                                          | " ) Password"  |
| ;                                       |                                                                                                                          | " ; Password"  |

## Return values

|   |                                            |
|---|--------------------------------------------|
| 0 | Normal termination                         |
| 1 | Abnormal termination (user-caused Error)   |
| 2 | Abnormal termination (miscellaneous Error) |

## Log output

- Output destination
  - In Windows:  
*Agent-path*\logs\tools\
  - In Linux:

## Example

- To add a secret:

```
> jimasecret -add -key Blackbox.http1.proxy_user.p-user01 -s password01
```

- To delete a secret:

```
> jimasecret -rm -key Blackbox.http1.proxy _user.p-user01
```

- To list the keys that have been added

```
> jimasecret -list  
Blackbox.http1.proxy_user.p-user01  
Blackbox.http1.basic_auth.w-user01  
immgr.proxy_user.user01
```

# jimasetup

---

## Function

This command performs the default Setup of JP1/IM - Agent.

## Format

```
jimasetup { phost | container }
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In Linux: Superuser permissions

## Storage directory

In Windows:

*Agent-path*\tools\

In Linux:

/opt/jplima/tools/

## Arguments

phost

If this option is specified when operating in physical host, it performs the initial Setup for operating in Physical host.

If you installed JP1/IM - Agent in a normal host deployment, the installer Execute `jimasetup phost` command.

If you created an AWS/EC2 virtual machine image, ensure that you Execute this command with `phost` optional specification from Auto Scaling scripting of AWS/EC2 before starting the service.

Cannot be specified together with `container` option.

container

If you created a container image, make sure that you execute this command with `container` optional specification from the scripts that the container execute before you start the service.

Cannot be specified together with `phost` option.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Log output

- Output destination

- In Windows:

*Agent-path*\logs\tools\

- In Linux:

/opt/jplima/logs/tools/

## Example

- Sample scripting specifications for AWS/EC2's Auto Scaling
  - In Windows:

```
<script>
Agent-path\tools\jimasetup phost
Agent-path\tools\jpc_service_start -s all
</script>
```

- In Linux:

```
#!/bin/sh
/opt/jplima/tools/jimasetup phost
/opt/jplima/tools/jpc_service_start -s all
```

- Sample specifications in scripts container executes
  - In Linux:

```
#!/bin/bash
/opt/jplima/tools/jimasetup container#1
exec /usr/local/bin/supervisord -c /opt/supervisord.conf#2
```

#1: Execute of initial setting command with container option.

#2: Execute the service management tools.

## Notes

- Do not execute this command multiple times at the same time. If you execute multiple times at the same time, even if the command terminates with normal, the result may be incorrect.
- This command must be executed on status where all JP1/IM - Agent services are down. If you execute the command in a status JP1/IM - Agent services are running, File that you are updating might become locked and fail to update.
- Be sure to execute this command with a status that does not have a defined file open, such as in a text editor. Updating file may fail if you execute the command when definition File is open, such as with a text editor.

# jimdbbackup

---

## Function

This command backs up the IM database. The following describes the purposes of making such a backup and the types of data that can be acquired.

### *Backup for error recovery*

You must back up the database periodically in order to recover the database in the event of a database failure. The database backup targets are the integrated monitoring database area, the IM Configuration Management database area, and the system database areas.

### *Backup for expansion*

When you are preparing to expand the size of the database, you must temporarily back up the database's data. The database backup targets are the integrated monitoring database area and the IM Configuration Management database area.

## Format

```
jimdbbackup -o backup-file-name
             -m {MAINT|EXPAND}
             [-h logical-host-name]
             [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdb\

In UNIX:

/opt/jplimm/bin/imdb/

## Arguments

-o *backup-file-name*

Specifies the absolute path name of the file to which the database is to be backed up. You must specify a logical drive or a backup file. This option is mandatory.

An error results if you specify a network drive, a UNC path, or a Windows reserved device file. If the specified backup file already exists, the existing file will be overwritten.

Make sure that the value you specify for *backup-file-name* includes a file path. The characters permitted for the file name are alphanumeric characters, the underscore (\_), dot (.), hash mark (#), and at mark (@). The character set also depends on the OS. If the name contains a space or a parenthesis ( ( or ) ), the entire name must be enclosed in double-quotation marks ("). In Windows, the backup file name when MAINT is specified must be in all lowercase letters. The maximum length of the file name depends on OS limitations.

If the directory for storing the specified backup file is not found, command execution fails. Make sure that you create the directory before you execute the command.

-m {MAINT|EXPAND}

Specifies the database backup format. The permitted characters are uppercase letters. This option is mandatory.

- MAINT: Specifies a backup for error recovery
- EXPAND: Specifies a backup for expansion

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host where the command is executed. The command backs up the database that corresponds to the specified logical host. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed. Note that this logical host name cannot be JP1\_DEFAULT. In addition, the logical host name is case sensitive.

-q

Specifies that the command is to be executed without requesting confirmation from the user.

## Return values

|   |                              |
|---|------------------------------|
| 0 | Backup terminated normally   |
| 1 | Backup terminated abnormally |

## Notes

- Before you execute this command, make sure that the execution conditions for the `jimdbrecovery` command are satisfied.
- If you execute another JP1/IM - Manager command or start a JP1/IM - Manager service while this command is executing, execution may fail because this command places the database in the mode that disables referencing and updating.
- While this command is executing, do not press **Ctrl +C** or **Ctrl + Break**. Because the command executes backup processing in the background, the backup processing will continue even though **Ctrl +C** or **Ctrl + Break** is pressed. If you press **Ctrl +C** or **Ctrl + Break** and then immediately attempt to execute another JP1/IM - Manager command or start a JP1/IM - Manager service, execution of the requested command or startup of the requested service may fail. If you have canceled command execution by pressing **Ctrl + C** or **Ctrl + Break**, first make sure that the following process is not executing, and then re-execute the command:
  - `pdcopy` process if you are performing a backup for error recovery
  - `pdrorg` process if you are performing a backup for expansion
- The `jimdbbackup` command creates a backup file during execution. In the case of a backup for expansion or a backup for error recovery, the amount of free space that is needed on the drive where the backup file is to be output is about 2 gigabytes for a small database, about 15 gigabytes for a medium-sized database, and about 50 gigabytes for a large database.
- When the IM database is used, JP1/IM - Manager must not be running.
- In Windows, the IM database (JP1/IM3-Manager DB Server) must be running, and the cluster service for the IM database (JP1/IM3-Manager DB Cluster Service\_*logical-host-name*) must be stopped.
- A backup file for recovery cannot be distinguished from a backup file for expansion. We recommend that you name the backup files so that you can distinguish between the types of backup files.

- At the time a backup file is output, it is in a status in which any user can access it. We recommend that immediately after you have made a backup, you change the access permissions or move the file to a protected location so that unauthorized users cannot access it.
- If you are using JP1/IM - MO, the JP1/IM - Message Optimizer service of JP1/IM - MO on the connection source must be stopped.
- Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.
- If you execute a disaster recovery backup, also consider backing up intelligent integrated management database.

# jimdbreclaim

## Function

This command releases free area (free page area) in the IM Configuration Management database.

If you delete a large number of hosts in the IM Configuration Management database, part of the area that was used to store that data might become used free area. This command changes used free area into unused free area so that it can be reused.

You can execute this command during operations without having to stop JP1/IM - Manager Service.

## Format

```
jimdbreclaim [-h logical-host-name]  
              [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdb\

In UNIX:

/opt/jplimm/bin/imdb/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host where the command is executed. The command releases free area in the IM Configuration Management database for the specified logical host. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed. Note that JP1\_DEFAULT cannot be specified for the logical host name. In addition, the logical host name is case sensitive.

-q

Specifies that the command is to be executed without requesting confirmation from the user.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Notes

- There is no need to execute this command unless you plan to repeatedly add or delete a large number of hosts in the IM Configuration Management database.

- If you execute another JP1/IM - Manager command while this command is executing, execution of the other command may fail.
- Because CPU load is high during execution of this command, we recommend that you execute it during a time when referencing and updating operations are at a minimum, such as at night.
- If you cancel this command's processing by pressing **Ctrl + C** or **Ctrl + Break**, release of free area in the database may fail. Before you re-execute the command, check that neither the `pdreclaim` process nor the `pdrorg` process is running. If either of these processes is running, wait a while and then check again.
- Do not stop the database service while this command is executing.  
If you have stopped the database service during execution of this command, you must start the database service and then re-execute the command.
- In Windows, the IM database service *JP1/IM3-Manager DB Server* must be running.
- Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.

# jimdbrecovery

---

## Function

This command recovers a database from its backup. The command can recover the following types of data:

Recovery for error recovery

In the event of a database failure, the command recovers the database from backup data that was acquired previously.

Recovery for expansion

Before you expand the size of a database, temporarily back up the data.

## Format

```
jimdbrecovery -i backup-file-name
               -m {MAINT|EXPAND}
               [-h logical-host-name]
               [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdb\

In UNIX:

/opt/jplimm/bin/imdb/

## Arguments

-i *backup-file-name*

Specifies the absolute path name of the file to which the database was backed up by the `jimdbbackup` command. The characters permitted for the file name are alphanumeric characters, the underscore (`_`), dot (`.`), hash mark (`#`), and at mark (`@`). You must specify a logical drive for the backup file. This option is mandatory.

An error results if you specify a network drive, a UNC path, or a Windows reserved device file.

-m {MAINT|EXPAND}

Specifies the database recovery format. The permitted characters are uppercase letters. This option is mandatory.

- MAINT: Specifies recovery for error recovery
- EXPAND: Specifies recovery for expansion

When you execute recovery for error recovery, specify the backup file that was acquired by a backup for error recovery; when you execute recovery for expansion, specify the backup file that was acquired by a backup for expansion. An error results if the specified argument does not match the type of backup file.

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host where the command is executed. The command recovers the database that corresponds to the specified logical host. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed. Note that JP1\_DEFAULT cannot be specified for the logical host name. In addition, the logical host name is case sensitive.

-q

Specifies that the command is to be executed without requesting confirmation from the user.

## Return values

|   |                                |
|---|--------------------------------|
| 0 | Recovery terminated normally   |
| 1 | Recovery terminated abnormally |

## Notes

- When you execute the `jimdbrecovery` command to recover backup data acquired by the `jimdbbackup` command, use the same OS that was used to make the backup. If the backup is recovered to a database under a different OS, the integrity of the operation cannot be guaranteed.
- If you execute another JP1/IM - Manager command or start a JP1/IM - Manager service while this command is executing, the requested execution might fail because this command places the database in the mode that disables referencing and updating.
- While this command is executing, do not press **Ctrl +C** or **Ctrl + Break**. Because the command executes recovery processing in the background, the recovery processing will continue even though **Ctrl +C** or **Ctrl + Break** is pressed. If you press **Ctrl +C** or **Ctrl + Break** and then immediately attempt to execute another JP1/IM - Manager command or start a JP1/IM - Manager service, execution of the requested command or startup of the requested service might fail. If you have canceled command execution by pressing **Ctrl +C** or **Ctrl + Break** during error recovery processing, make sure that the `pdrstr` process is not running before you restart JP1/IM - Manager. If you have canceled command execution by pressing **Ctrl +C** or **Ctrl + Break** during a recovery for expansion, make sure that the `pdrorg` process is not running before you start another command or a JP1/IM - Manager service.
- This command creates a temporary file during execution. In the case of a recovery for expansion, the amount of free space needed on the drive where the IM database is to be installed is about 1 gigabyte for a small or medium-sized database, and about 4 gigabytes for a large database. In the case of a recovery for error recovery, the amount of free space needed on the drive can vary from about 5 to 50 megabytes, regardless of the database size.
- When you execute a recovery for error recovery, the database storage directory used to execute the backup for error recovery must be the same as the database storage directory used to execute the recovery for error recovery.
- When you execute a recovery for expansion, the storage space must be larger than when the backup for expansion was executed.
- Recovery for expansion might fail if the available capacity is the same as for the backup for expansion. If this occurs, set up the database again and then, with the database free of data, recover the database.
- When the IM database is used, JP1/IM - Manager must not be running.
- In Windows, the IM database (JP1/IM3-Manager DB Server) must be running and the cluster service for the IM database (JP1/IM3-Manager DB Cluster Service\_*logical-host-name*) must be stopped.
- If you are using JP1/IM - MO, the JP1/IM - Message Optimizer service of JP1/IM - MO on the connection source must be stopped.

- Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.
- If you execute a disaster recovery backup, also consider backing up intelligent integrated management database.

## Function

This command reorganizes fragmented free space in the IM Configuration Management database. Free space in use is released by reorganization. Therefore, you do not need to execute the `jimdbreclaim` command many times.

When you perform maintenance of JP1/IM - Manager, you can also resolve low data storage efficiency caused by fragmentation by executing database reorganization.

## Format

```
jimdborg [-h logical-host-name]  
          [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdb\

In UNIX:

/opt/jp1imm/bin/imdb/

## Arguments

`-h logical-host-name`

When you are operating in a cluster system, this option specifies the logical host name of the host where the command is executed. The command reorganizes the database for the specified logical host. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed. Note that this logical host name cannot be `JP1_DEFAULT`. In addition, the logical host name is case sensitive.

`-q`

Specifies that the command is to be executed without requesting confirmation from the user.

## Return values

|   |                                      |
|---|--------------------------------------|
| 0 | Reorganization terminated normally   |
| 1 | Reorganization terminated abnormally |

## Notes

- If you execute another JP1/IM - Manager command or start a JP1/IM - Manager service while this command is executing, the requested execution might fail.

- While this command is executing, do not press **Ctrl +C** or **Ctrl + Break**. Because the command executes database reorganization processing in the background, the database reorganization processing will continue even though **Ctrl +C** or **Ctrl + Break** is pressed. If you press **Ctrl +C** or **Ctrl + Break** and then immediately attempt to execute another JP1/IM - Manager command or start a JP1/IM - Manager service, execution of the requested command or startup of the requested service may fail.

If you have canceled command execution by pressing **Ctrl +C** or **Ctrl + Break**, you must use a method such as the Windows Task Manager to make sure that the `pdrorg` process is not running before you execute another JP1/IM - Manager command or use JP1/IM - Manager. If the `pdrorg` process is running, wait until it terminates before executing another JP1/IM - Manager command or using JP1/IM - Manager.

- We recommend that you make a backup for error recovery before and after you execute this command.
- This command creates a temporary file during execution. For this reason, the amount of free space needed on the drive where the IM database is to be installed is about 1 gigabyte for a small or medium-sized database and about 4 gigabytes for a large database.
- When the IM database is used, JP1/IM - Manager must not be running.
- In Windows, the IM database (JP1/IM3-Manager DB Server) must be running and the cluster service for the IM database (JP1/IM3-Manager DB Cluster Service\_*logical-host-name*) must be stopped.
- If you are using JP1/IM - MO, the JP1/IM - Message Optimizer service of JP1/IM - MO on the connection source must be stopped.
- Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.

# jimdbstatus

---

## Function

This command checks the operating status of the IM database, such as running or stopped.

## Format

```
jimdbstatus [-h logical-host-name]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdb\

In UNIX:

/opt/jplimm/bin/imdb/

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the logical host name of the host where the command is executed. The command then checks the operating status of the IM database for the specified logical host. If this option is omitted, the logical host name specified in the JP1\_HOSTNAME environment variable is assumed. If the JP1\_HOSTNAME environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed. Note that the logical host name is case sensitive.

## Return values

|    |                                                                                                                |
|----|----------------------------------------------------------------------------------------------------------------|
| 0  | IM database is running                                                                                         |
| 1  | jimdbstatus command terminated abnormally                                                                      |
| 4  | IM database is engaged in startup or termination processing                                                    |
| 8  | Database has been terminated (IM database restart processing was canceled and the IM database became unstable) |
| 12 | IM database was terminated (normal termination status)                                                         |
| 16 | IM database has not been started (applicable to Windows)                                                       |
| 20 | IM database has not been set up                                                                                |

## Notes

Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.

# jimdbstop

## Function

This command terminates the IM database. Use this command to set the termination command with the start sequence control function of JP1/Base.

If the IM database is in restart canceled status, you can forcibly terminate it by executing this command with the `-f` option specified.

## Format

```
jimdbstop [-h logical-host-name]  
          [-f]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imdb\

In UNIX:

/opt/jplimm/bin/imdb/

## Arguments

`-h logical-host-name`

When you are operating in a cluster system, this option specifies the logical host name of the host where the command is executed. The command then stops the IM database for the specified logical host. If this option is omitted, the logical host name specified in the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you are not using a cluster system, specification of this option is not needed. Note that the logical host name is case sensitive.

`-f`

Specifies that the IM database is to be terminated forcibly.

## Return values

|    |                                                                                                                |
|----|----------------------------------------------------------------------------------------------------------------|
| 0  | Normal termination                                                                                             |
| 1  | Abnormal termination                                                                                           |
| 4  | IM database is engaged in startup or termination processing                                                    |
| 8  | Database has been terminated (IM database restart processing was canceled and the IM database became unstable) |
| 12 | IM database was terminated (normal termination status)                                                         |
| 20 | IM database has not been set up                                                                                |

## Notes

- If you cancel processing by pressing **Ctrl + C** or **Ctrl + Break**, termination of the IM database might fail. If you re-execute the command in such a case, first make sure that the `pdstop` process is not running. If the `pdstop` process is running, wait a while and then check again.
- JP1/IM - Manager must not be running while the IM database is being used.
- If you are using JP1/IM - MO, the JP1/IM - Message Optimizer service of JP1/IM - MO on the connection source must be stopped.
- Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.

# jimdbupdate

## Function

This command updates an IM database that has already been set up. Execute this command after upgrading JP1/IM - Manager.

## Format

```
jimdbupdate [-h logical-host-name] [-i] [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

```
Manager-path\bin\imdb\
```

In UNIX:

```
/opt/jplimm/bin/imdb/
```

## Arguments

-h *logical-host-name*

When you are operating in a cluster system, this option specifies the name of the logical host where this command is to be executed. Execution of the command updates the IM database for the specified logical host. If you do not use a cluster system, specification of this option is not needed. Note that JP1\_DEFAULT cannot be specified for the logical host name. In addition, the logical host name is case sensitive. For the logical host name, specify a logical host name set in JP1/Base in the correct form, especially case.

-i

Specify this option to update the IM database. If this option is omitted, a message asking whether the IM database needs to be updated is displayed.

-q

Specify this option to execute the command without requiring user confirmation.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Notes

- Before executing this command, make sure that the following execution conditions for this command are satisfied.  
Execution conditions
  - When this command is executed on the active server, the shared disk must be online and the logical host name must be able to be resolved.

- In Windows, the IM database must be started.

For a physical host:

- JP1/IM3-Manager DB Server

For a logical host:

- JP1/IM3-Manager DB Server\_*logical-host-name*

In addition, the JP1/IM - Manager service and the cluster service for the IM database indicated below must be stopped. Note, however, that if the integrated monitoring database and the IM configuration management database are not used, it is not necessary to stop the JP1/IM - Manager service.

For a physical host:

- JP1/IM - Manager service (JP1/IM3-Manager)
- Cluster service for the IM database (JP1/IM3-Manager DB Cluster Service)

For a logical host:

- JP1/IM - Manager service (JP1/IM3-Manager\_*logical-host-name*)
- Cluster service for the IM database (JP1/IM3-Manager DB Cluster Service\_*logical-host-name*)

- In UNIX, the JP1/IM - Manager service must be stopped. Note, however, that if the integrated monitoring database and the IM configuration management database are not used, it is not necessary to stop the JP1/IM - Manager service.
- If the command is stopped during execution by pressing the **Ctrl** and **C** keys or the **Ctrl** and **Break** keys, re-execute the command after making sure that the `pdeinstall` process is not being executed.
- After executing the `jimdbupdate` command, you will not be able to recover the expansion backup from the previous execution of the `jimdbupdate` command. We recommend that you make another expansion backup after executing the `jimdbupdate` command.
- After executing the command, do not attempt to recover backup data from the existing IM database that was acquired before this command was executed. We recommend that you use the `jimdbbackup` command to make another backup after executing this command.
- During execution of the `jimdbupdate` command, do not execute `jimdbstatus` or other commands related to the IM database. If you do, you might not be able to uninstall the IM database.
- Before executing the command in Windows, in case of existing the Application Experience service, make sure that the startup type of the Application Experience service is not set to **Disabled**.
- If you are upgrading JP1/IM - Manager from version earlier than 13-00 to 13-00 or later and then execute `jimdbupdate` command, note the following:
  - After September 29, 2034, do not execute `jimdbupdate` command. Perform manual uninstallation and new setup of IM database.

For Windows, also note the following:

- During command execute, do not use the **Ctrl** + **C** keys or the **Ctrl** + **Break** keys to abort the process. If you cancel, you may need to Redo JP1/IM - Manager version upgrade.
- When updating IM database, close the application that locks File of IM database. If they are operating, updating may fail and redo of JP1/IM - Manager version upgrade may be required. For antivirus software, this step is required if IM database's install directory and data storage directory are not excluded from checking.
- If IM database update fails and KNAN11215-E message is output, follow the instructions in *12.5.3(69) What to do if updating IM database with jimdbupdate command fails and a KNAN11215-E message is displayed in the JP1/Integrated Management 3 - Manager Administration Guide*.

For Linux, also note the following:

- Execute the command with Status whose SELinux is disabled.

# jimgndbbackup

---

## Function

This command backs up intelligent integrated management database.

The purpose of backup and the types of data that can be acquired are shown below.

### Backup for disaster recovery

Backs up your data regularly to recover your database in the event of a database failure. The backed up areas are Trend data Management Database space, Integrated agent host Administration Database space, Dashboard Management Database space, and Response Action results management database space in the database.

### Migration backup

Backs up the data to migrate the definition information in the database when migrating JP1/IM - Manager to another host. The backed up areas are Trend data Management Database space, Dashboard Management Database space, and Integrated agent host Administration Database space in the database.

The following shows Execute conditions for this command:

- There is sufficient free space on the destination drive to store the backup file to be created when this command is run.  
You must have at least as much free space as the data files for the Intelligent Integrated Management database. For details about the data files for the Intelligent Integrated Management database, see *Data file storage of the Intelligent Integrated Management database* section of 2.7.1(1)(d) *Where related files are stored* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.
- Stopping the following services:
  - JP1/IM3-Manager
  - JP1/IM3-Manager Intelligent Integrated DB Server
  - JP1/IM3-Manager Trend Data Management Service
- Stopping the following services when using cluster systems:
  - JP1/IM3-Manager\_ *logical-host-name*
  - JP1/IM3-Manager Intelligent Integrated DB Server\_ *logical-host-name*
  - JP1/IM3-Manager Trend Data Management Service\_ *logical-host-name*
- If this command is run with the MAINT option for argument -m, a backup of the IM database must have been taken using the jimgdbbackup command (with the MAINT option specified for the -m argument).

## Format

```
jimgndbbackup -o directory-name  
               -m {MAINT|TRANSF}  
               [-h logical-hostname]  
               [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imgndb\

In UNIX:

/opt/jplimm/bin/imgndb/

## Arguments

-o *directory-name*

Specifies the absolute path of directory to which the database to be backed up is to be exported. The following backup files will be output to the specified directory.

- For disaster recovery backup

- jimgndbbbackup\_maint\_1
- jimgndbbbackup\_maint\_2

- For migration backup

- jimgndbbbackup\_transf1
- jimgndbbbackup\_transf2

Please specify a local drive for the directory. This option cannot be omitted.

Error if a network drive is specified, UNC path is specified, and reserved device File is specified in Windows. If the backup file already exists in the specified directory, it is overwritten.

The characters that can be used in the directory name depend on the operating system. If the name contains a single-byte space or parentheses " (" or " ) ", it must be enclosed in double quotes. Additionally, the directory name can be up to 233 characters long.

-m {MAINT|TRANSF}

Specifies the database backup format. Half-width capital alphabet. This option cannot be omitted.

- MAINT: Execute the backup for disaster recovery.
- TRANSF: Execute the backup for migration.

-h *logical-hostname*

Specifies Logical host name of the host that Execute the command when operating in a cluster system. Backs up Intelligent Integrated Management Database corresponding to the specified Logical host. If this option is omitted, Logical host named in the environment variable JP1\_HOSTNAME is assumed. If JP1\_HOSTNAME is not specified, Physical host is assumed. If you are not using a cluster system, you do not need to specify it. Note that JP1\_DEFAULT cannot be specified in a Logical host.

-q

Specifies when you execute the command without user-confirmation.

## Return values

|   |                                                                                      |
|---|--------------------------------------------------------------------------------------|
| 0 | The backup terminated normally                                                       |
| 1 | The backup terminated abnormally                                                     |
| 3 | Canceled by user (if you enter N/n in KNAN12009-Q Message and Stopped the operation) |

## Notes

- Before you Execute this command, make sure that Execute conditions for this command and `jimgndbrestore` command are met.
- Do not start services or execute commands of other JP1/IM - Manager or JP1/IM - Agent while this command is working, Execute may fail because this command changes the database to read/write disabled mode.
- Do not press the **Ctrl + C** keys or the **Ctrl + Break** keys while this command is working. To execute the backup in the background, pressing **Ctrl + C** keys or **Ctrl + Break** keys will not stop the backup process. If you immediately start a Execute a command or start service for another JP1/IM - Manager or JP1/IM - Agent after pressing **Ctrl + C** keys or **Ctrl + Break** keys, execute or service for those commands may fail.
- If the **Ctrl + C** keys or the **Ctrl + Break** keys are used to abort the process while commands are working, the process is turned Stopped, but output Message may be corrupted.
- The access permissions for the backup file are printed in Status that the user can access. After making a backup, we recommend that you change the access permissions or move them to a location where users cannot access them.
- You cannot execute this command in multiple execution or concurrently with Intelligent Integrated Management Database operation commands. For details about Intelligent Integrated Management Database operation command multiplexing execute, see About multiple execution of the commands related to the Intelligent Integrated Management Database.

## Function

This command recovers Intelligent Integrated Management Database that was saved as a backup. The following are the types of data that can be recovered:

### Disaster recovery

When a database failure occurs, the database is recovered using the backup data that is regularly acquired.

### Migration recovery

When you migrate a JP1/IM - Manager to another host, you use the backed-up data to migrate the database.

The following shows Execute conditions for this command:

- Stopping the following services:
  - JP1/IM3-Manager
  - JP1/IM3-Manager Intelligent Integrated DB Server
  - JP1/IM3-Manager Trend Data Management Service
- Stopping the following services when using cluster systems:
  - JP1/IM3-Manager\_*logical-host-name*
  - JP1/IM3-Manager Intelligent Integrated DB Server\_*logical-host-name*
  - JP1/IM3-Manager Trend Data Management Service\_*logical-host-name*
- If this command is run with the MAINT option for argument -m, the IM database must have been recovered using the jimgdbrecovery command (with the MAINT option specified for the -m argument).
- Intelligent Integrated Management Database has been re-constructed.

## Format

```
jimgndbrestore -i directory-name
                -m {MAINT|TRANSF}
                [-h logical-hostname]
                [-q]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imgndb\

In UNIX:

/opt/jplimm/bin/imgndb/

## Arguments

**-i** *directory-name*

Specifies the absolute path of directory where backup files of the database were backed up using `jimgndbbackup` command. The following backup files stored in the specified directory will be used. If there are any files other than the ones listed below in the specified directory, those files will be ignored.

- For disaster recovery backup

- `jimgndbbackup_maint_1`
- `jimgndbbackup_maint_2`

- For migration backup

- `jimgndbbackup_transf1`
- `jimgndbbackup_transf2`

Please specify a local drive for the directory. This option cannot be omitted.

Error if a network drive is specified, UNC path is specified, and reserved device File is specified in Windows.

**-m** {MAINT | TRANSF }

Specifies the database recovery format. Characters that can be specified are uppercase single-byte characters. This option cannot be omitted.

- MAINT: Execute the disaster recovery.
- TRANSF: Execute the recovery for migration.

When you execute disaster recovery, specify the backup file that was collected in the backup for disaster recovery.

When you execute the recovery for migration, specify the backup file that was collected in the backup for migration.

**-h** *logical-hostname*

Specifies logical host name of the host that execute the command when operating in a cluster system. The database is recovered for the specified logical host. If this option is omitted, logical host named in the environment variable `JP1_HOSTNAME` is assumed. If `JP1_HOSTNAME` is not specified, Physical host is assumed. If you are not using a cluster system, you do not need to specify it. Note that `JP1_DEFAULT` cannot be specified in a logical host.

**-q**

Specifies when you execute the command without user-confirmation.

## Return values

|   |                                                                                      |
|---|--------------------------------------------------------------------------------------|
| 0 | The recovery terminated normally                                                     |
| 1 | The recovery terminated abnormally                                                   |
| 3 | Canceled by user (if you enter N/n in KNAN12009-Q Message and Stopped the operation) |

## Notes

- Before you Execute this command, make sure that Execute conditions for this command and `jimgndbbackup` command are met.
- Recovering the database may cause data inconsistency between the database and JP1/IM-Agent. To prevent the data inconsistency, stop JP1/IM-Agent before recovering the database.
- This command recovers only the data in the database. To prevent data inconsistency between backup data and the data added after the backup has been taken, you must first set up the database again before recovering the database. If data inconsistency occurs, the impact can be diverse, and it is difficult to later discover the data inconsistency. Therefore, be sure to set up the database again before performing a recovery.

- While this command is working, do not start service or any other commands of JP1/IM - Manager or JP1/IM - Agent. This command might fail because this command changes the database-browsing/updating state to prohibited.
- Do not press the **Ctrl + C** keys or the **Ctrl + Break** keys while this command is working. To execute the backup in the background, pressing **Ctrl + C** keys or **Ctrl + Break** keys will not stop the backup process. If you immediately execute a command or start service for another JP1/IM - Manager or JP1/IM - Agent after pressing **Ctrl + C** keys or **Ctrl + Break** keys, execute or service for those commands may fail.
- If the **Ctrl + C** keys or the **Ctrl + Break** keys are used to abort the process while this command is working, the process is turned Stopped, but the output message may be corrupted.
- You cannot execute this command in multiple execution or concurrently with Intelligent Integrated Management Database operation commands. For details about Intelligent Integrated Management Database operation command multiplexing execute, see About multiple execution of the commands related to the Intelligent Integrated Management Database.
- For the directory name specified with the `-i` option, please specify the directory that contains the backup files obtained from the same OS.

# jimgndbsetup

---

## Function

Set up (install and build databases) Intelligent Integrated Management Database and Trend Data Management Services.

Also, if set up already, check and modify Setup of the database.

## Format

```
jimgndbsetup  {-f setup-information-file-name
               [-h logical-host-name -c {online|standby}]
               [-q]
               | -display [-h logical-host-name] }
```

The command arguments are in no particular order.

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In Linux: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imgndb\

In Linux:

/opt/jplimm/bin/imgndb/

## Arguments

**-f *setup-information-file-name***

Specifies the directory where Intelligent Integrated Management Database is installed and setup information file for the IM database that describes Port number. Depending on the configuration of Intelligent Integrated Management Database, specify the following File:

When building in a physical host environment

Intelligent Integrated Management Database Setup Information File Name

When building in a cluster environment

Cluster Environment Intelligent Integrated Management Database Setup Information File Name

The file name is specified in the form of a full path or a path relative to where this command is run. If the path contains spaces, enclose it in "".

**-h *logical-host-name***

If the cluster environment Intelligent Integrated Management database setup information file name is specified on the -f option, a logical host name is required. For the logical host name, specify the logical host name set in JP1/Base exactly, including uppercase and lowercase letters.

Sets up the Intelligent Integrated Management database for the specified logical host. If you are not using a cluster system, you do not need to specify it.

Note that JP1\_DEFAULT cannot be specified for the logical host name.

`-c {online|standby}`

When the `-h` option is specified, the setup type of the execution system and the standby system of the cluster configuration is specified as required. The following are the setup types that you can specify:

- `online`  
Specify to set up an execution system.
- `standby`  
Specify to set up a standby system.  
Only install Intelligent Integrated Management Database and skip building databases.

If standby is specified on the `-c` option on both the execution system and the standby system, the database will not be built. In this case, unset after the command ends, and then rerun the command.

Also, when operating a logical host in a non-clustered environment, specify `online`.

`-q`

Specifies that the command is to be executed without user confirmation.

`-display`

Specify if you want to check if Intelligent Integrated Management Database and Trend Data Management Services are built.

If it is already built, the following setup setting information is output as a KNAN12094-I message.

- Port number of the intelligent integrated management database
- Trend Data Management Service port number
- Data storage directory
- Installation directory
- Trend data retention period
- Trend data management database maximum disk size
- Period of data to be deleted when the maximum disk size is approaching

## Return values

|   |                                                                                      |
|---|--------------------------------------------------------------------------------------|
| 0 | Normal termination                                                                   |
| 1 | Abnormal termination                                                                 |
| 2 | Abnormal termination (If you suspect that a file or process may remain)              |
| 3 | Canceled by user (if you enter N/n in KNAN12009-Q Message and Stopped the operation) |

## Log output

This command outputs the following trace log for each process: The integrated trace log is not output.

- File name  
`jimgndbsetup{1|2}.log#`  
#: {1|2} is a number of faces of the file.
- File size (number of faces)  
256KB (2 faces)
- Output destination

- In Windows:

- Physical host and Logical host  
*Manager-path\log\imgndb\*

- In Linux:

- Physical host and Logical host  
*/var/opt/jplimm/log/imgndb/*

## Notes

- The contents of the executable and standby cluster environment intelligent integrated management database setup information files must be the same. When setting up the standby system, copy and use the cluster environment intelligent integrated management database setup information file used in the execution system. If the contents of the file specified in the execution system and the standby system are different, after unsetting on the standby system, copy the cluster environment intelligent integrated management database setup information file from the execution system and reexecute the command.
- When executing a command with the `-c` option, do not switch servers during execution. If you switch servers while running, unset them up after the command ends, and then rerun the command.
- The following are precautions when processing is aborted by pressing **Ctrl + C** or **Ctrl + Break** during command execution.
  - Ensure that the `pg_ctl`, `postgres`, and `promscale` processes are not running, run the `jimgndbunsetup` command, and rerun the command. If these processes are running, wait some time for them to end and rerun this command.
  - Processing is aborted, but messages may be output corrupted.
  - If you want to execute the command again after stopping the process, check the directory specified in the entry "IMGNDBDIR" of the Intelligent Integrated Management Database Setup Information File or the entry "SHAREGNDBDIR" of the Cluster Environment Intelligent Integrated Management Database Setup Information File, and if the file or directory exists, Remove them and empty them before running.
- This command cannot be multiplexed. It cannot be run concurrently with other operational commands in the Intelligent Integrated Administration database.

For details about Intelligent Integrated Management Database operation command multiplexing execute, see [About multiple execution of the commands related to the Intelligent Integrated Management Database](#).
- If you change the logical host settings with this command, the service remains stopped without restarting. In this case, you must manually start the service after running the command.
- Since the Intelligent Integrated Management Database communicates with localhost, the IP address of localhost must be resolvable. Otherwise, setup fails.
- When running in a domain environment, if the user who executes the command has the same name in the domain user and the local account of that environment, the command execution fails. Therefore, execute the command with the username of the local account.

## Example 1

- In case of successful completion

```
>jimgndbsetup -f intelligent-integrated-management-database-setup-informat
ion-file-name
KNAN12005-I The Intelligent Integrated Management Database will be set up.
KNAN12088-I Intelligent Integrated Management Database installation direct
ory : directory-name
KNAN12006-I Data storage directory for the Intelligent Integrated Manageme
nt Database : directory-name
```

```
KNAN12007-I Port number for the Intelligent Integrated Management Database : port-number
KNAN12008-I Data retention period for the Trend Data Management Database : data-saved-period
KNAN12009-Q Do you want to continue processing? (Y/N) :Y
KNAN12010-I Setup for the Intelligent Integrated Management Database will now start.
KNAN12020-I Please wait.
KNAN12089-I The Intelligent Integrated Management Database will be installed.
KNAN12090-I The Intelligent Integrated Management Database has been installed.
KNAN12013-I The Intelligent Integrated Management Database will be configured.
KNAN12014-I The Intelligent Integrated Management Database was configured.
KNAN12012-I Setup for the Intelligent Integrated Management Database ended normally.
```

- In case of an abend (when the required fields in the Intelligent Integrated Management database setup information file are not specified)

```
>jimgndbsetup -f intelligent-integrated-management-database-setup-information-file-name
KNAN12005-I The Intelligent Integrated Management Database will be set up.
KNAN12022-E One or more required items are not specified in the database setup information file. (item name : item-name)
```

## Example 2

- If you want to check the configured information

```
>jimgndbsetup -display
KNAN12094-I The Intelligent Integrated Management Database is already set up.
Port number for the Intelligent Integrated Management Database : port-number
Port number for the trend data management service : port-number
Data storage directory : directory-path
Installation directory : directory-path
Trend data retention period : retention-period
Trend data management database maximum disk size : disk-size
Duration of data to delete when the maximum disk size is approaching : Deletion-period
```

## Example 3

- If you want to change the settings

```
>jimgndbsetup -f intelligent-integrated-management-database-setup-information-file-name
KNAN12005-I The Intelligent Integrated Management Database will be set up.
KNAN12088-I Intelligent Integrated Management Database installation directory : /var/opt/jplimm/dbms
KNAN12006-I Data storage directory for the Intelligent Integrated Management Database : /var/opt/jplimm/database
KNAN12007-I Port number for the Intelligent Integrated Management Database : 20705
KNAN12008-I Data retention period for the Trend Data Management Database
```

: 64

KNAN12015-I The settings of the Intelligent Integrated Management Database will be changed.

The Integrated Management Database will restart after the settings are changed.

KNAN12009-Q Do you want to continue processing? (Y/N) : Y

KNAN12020-I Please wait.

KNAN12016-I The settings of the Intelligent Integrated Management Database were changed.

# jimgndbstatus

---

## Function

This command checks the operating Status, such as starting and stopping Intelligent Integrated Management Database service and the trend data management service.

If the `-ri` option is specified, you can check the retention period of the Intelligent Integrated Management Database (Trend Data Management DB).

When the `-rs` option is specified, you can check the last execution date, end date, and next scheduled execution date for the process of deleting data that has exceeded the retention period of the Intelligent Integrated Management Database (Trend Data Management DB).

## Format

```
jimgndbstatus [{-ri | -rs}]  
               [-h logical-host-name]
```

The command arguments are in no particular order.

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In Linux: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imgndb\

In Linux:

/opt/jplimm/bin/imgndb/

## Arguments

`-ri`

When this option is specified, the retention period of trend data in the trend data management DB is output as the KNAN12099-I message.

`-rs`

When this option is specified, the trend data in the trend data management DB checks whether the retention period has expired and outputs the following information about the execution schedule of the deletion process of the data that has exceeded the retention period in the KNAN12054-I message.

- Last start date and time (start date and time of last run)
- Last end date and time (end date and time of last run)
- Next start date and time (next execution start date and time)

For details about the KNAN12054-I message, including the formats for Date/time files (Last Date/time, Last Date/time, Next Start Date/time), see the *JP1/Integrated Management 3 - Manager Messages*.

-h *logical-host-name*

When operating on a clustered system, specify the logical host name of the host on which the command is executed. Checks the operating Status of Intelligent Integrated Management Database corresponding to the specified Logical host. If you are not using a cluster system, you do not need to specify it.

If this option is omitted, the logical host name specified in the environment variable JP1\_HOSTNAME is assumed. If the environment variable JP1\_HOSTNAME is not specified, the physical host name is assumed.

Note that JP1\_DEFAULT cannot be specified for the logical host name.

## Return values

|    |                                                                                                                                                                                                                                                                                                            |
|----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | <ul style="list-style-type: none"><li>If neither the -ri option nor the -rs option is specified<br/>Intelligent Integrated Management Database and Trend Data Management Service are up and running.</li><li>When either the -ri option or the -rs option is specified<br/>Successful completion</li></ul> |
| 1  | Abnormal termination                                                                                                                                                                                                                                                                                       |
| 12 | Intelligent Integrated Management Database and Trend Data Management Service are stopped.                                                                                                                                                                                                                  |
| 16 | The Intelligent Integrated Management Database is up and the Trend Data Management Service is stopped.                                                                                                                                                                                                     |
| 17 | The Intelligent Integrated Management Database is stopped, and the Trend Data Management Service is started.                                                                                                                                                                                               |
| 20 | Intelligent Integrated Management database not set up                                                                                                                                                                                                                                                      |

## Log output

This command outputs the following trace log for each process: The integrated trace log is not output.

- File name

jimgndbstatus{1|2|3|4|5|6|7|8|9|10}.log#  
#: {1|2|3|4|5|6|7|8|9|10} is a number of faces of the file.

- File size (number of faces)

5,120KB (10 faces)

- Output destination

- In Windows:

- Physical host

*Manager-path*\log\imgndb\#

- Logical host

*user-specified-path-when-created-logical-host-of-JP1/IM - Manager*\log\imgndb\

- In Linux:

- Physical host

/var/opt/jplimm/log/imgndb/#

- Logical host

*user-specified-path-when-created-logical-host-of-JP1/IM - Manager*/jplimm/log/imgndb/

#

Even in the operation of a logical host, a portion of the log is output to the physical host.

## Notes

- For details about Intelligent Integrated Management Database operation command multiplexing execute, see [About multiple execution of the commands related to the Intelligent Integrated Management Database](#).
- If "unknown" is displayed in the date and time information when the command is executed with the `-rs` option, it is possible that automatic deletion of trend data is in progress. In this case, you can wait a few moments and run the command again to obtain information about the execution schedule.

## Example 1

- If neither the `-ri` option nor the `-rs` option is specified and the result is successful.

```
>jimgndbstatus
KNAN12044-I The processing to confirm the service operating status will no
w start.
KNAN12047-I The Intelligent Integrated Management Database Service is runn
ing.
KNAN12048-I The trend data management service is running.
KNAN12045-I The processing to confirm the service operating status ended n
ormally.
```

## Example 2

- If the `-ri` option is specified and the end is successful.

```
>jimgndbstatus -ri
KNAN12044-I The processing to confirm the service operating status will no
w start.
KNAN12099-I The retention period is as follows:
32 days
KNAN12045-I The processing to confirm the service operating status ended n
ormally.
```

## Example 3

- If the `-rs` option is specified and the end is successful.

```
>jimgndbstatus -rs
KNAN12044-I The processing to confirm the service operating status will no
w start.
KNAN12054-I The previous and next execution schedules are as follows.
Previous start date and time : [2021-07-15 17:31:06.83+09]
Previous end date and time : [2021-07-15 17:31:07.08+09]
Next start date and time : [2021-07-15 18:01:07.08+09]
KNAN12045-I The processing to confirm the service operating status ended n
ormally.
```

# jimgndbstop

---

## Function

This command stops Intelligent Integrated Management Database and Trend Data Management service.

To force the Intelligent Integrated Management database to stop, use this command with the `-f` option.

The waiting time for stopping the trend data management service is up to 10 seconds<sup>#</sup>.

#

The waiting time for a typical outage process is up to 5 seconds. If the `-f` option is specified, a maximum of 5 seconds is added to the waiting time for forced stop processing.

Also, if you are using setup to automatically start and terminate JP1/IM - Manager, use the `jco_stop` command to stop Intelligent Integrated Management Database and Trend Data Management Service. For details about the `jco_stop` command, see *jco\_stop (UNIX only)*.

## Format

```
jimgndbstop  -sys  
              [-h logical-host-name]  
              [-f]
```

The command arguments are in no particular order.

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In Linux: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imgndb\

In Linux:

/opt/jplimm/bin/imgndb/

## Arguments

`-sys`

Required when this command is run. This is an option to prevent unintentional service outages.

`-h logical-host-name`

When operating on a clustered system, specify the logical host name of the host on which the command is executed.

Stops the Intelligent Integrated Management Database (service) and the Trend Data Management service corresponding to the specified logical host. If you are not using a cluster system, you do not need to specify it.

If this option is omitted, the logical host name specified in the environment variable `JP1_HOSTNAME` is assumed.

If the environment variable `JP1_HOSTNAME` is not specified, the physical host name is assumed.

Note that `JP1_DEFAULT` cannot be specified for the logical host name.

-f

Specifies that Intelligent Integrated Management Database is to be forcibly stopped.

## Return values

|    |                                                       |
|----|-------------------------------------------------------|
| 0  | Normal termination                                    |
| 1  | Abnormal termination                                  |
| 20 | Intelligent Integrated Management database not set up |

## Log output

This command outputs the following trace log for each process: The integrated trace log is not output.

- File name  
`jimgndbstop{1|2|3|4|5|6|7|8|9|10}.log#`  
#: {1|2|3|4|5|6|7|8|9|10} is a number of faces of the file.
  - File size (number of faces)  
5,120KB (10 faces)
  - Output destination
    - In Windows:
      - Physical host  
`Manager-path\log\imgndb\#`
      - Logical host  
`user-specified-path-when-created-logical-host-of-JP1/IM - Manager\log\imgndb\`
    - In Linux:
      - Physical host  
`/var/opt/jplimm/log/imgndb/#`
      - Logical host  
`user-specified-path-when-created-logical-host-of-JP1/IM - Manager/jplimm/log/imgndb/`
- #

Even in the operation of a logical host, a portion of the log is output to the physical host.

## Notes

- This command cannot be multiplexed. It cannot be run concurrently with other operational commands in the Intelligent Integrated Administration database.  
For details about Intelligent Integrated Management Database operation command multiplexing execute, see [About multiple execution of the commands related to the Intelligent Integrated Management Database](#).
- If you run this command and fail to stop the Intelligent Integrated Management Database and the Trend Data Management Service:  
Check the error message printed to the console, remove the cause of the error, and stop again with this command.  
If it still does not stop, stop the process using the OS function.  
For details about the process to be stopped, see *JP1/IM - Manager process (Linux)* in *Appendix B. Process List of the JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## Example

- In case of successful completion

```
> jimgndbstop -sys
KNAN12064-I The trend data management service will now stop.
KNAN12068-I The trend data management service stopped.
KNAN12066-I The trend data management service stopped normally.
KNAN12063-I The Intelligent Integrated Management Database Service will now stop.
KNAN12067-I The Intelligent Integrated Management Database Service stopped.
KNAN12065-I The Intelligent Integrated Management Database Service stopped normally.
```

- In case of abend (when the database is not set up)

```
> jimgndbstop -sys
KNAN12063-I The Intelligent Integrated Management Database Service will now stop.
KNAN12041-E The Intelligent Integrated Management Database is not configured.
```

# jimgndbunsetup

---

## Function

This command uninstalls Intelligent Integrated Management Database and Trend Data Management Service (uninstall and delete the database).

Execute this command before stopping the use of Intelligent Integrated Management Database or re-creating Intelligent Integrated Management Database. If you want to uninstall both Physical host and Logical host, you must Execute them on each host.

## Format

```
jimgndbunsetup [-h logical-host-name -c {online|standby}]  
               [-q]
```

The command arguments are in no particular order.

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In Linux: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\imgndb\

In Linux:

/opt/jplimm/bin/imgndb/

## Arguments

**-h *logical-host-name***

When operating on a clustered system, specify the logical host name of the host on which the command is executed. For the logical host name, specify the logical host name set in JP1/Base exactly, including uppercase and lowercase letters.

Intelligent Integrated Management Database corresponding to the specified Logical host will be uninstalled. If you are not using a cluster system, you do not need to specify it.

Note that JP1\_DEFAULT cannot be specified for the logical host name.

**-c {online|standby}**

Specify the setup type of the execution system and standby system of the cluster configuration as required. The following are the setup types that you can specify:

- online

Specify to set up an execution system.

- standby

Specify to set up a standby system.

Only uninstall Intelligent Integrated Management Database and skip delete of the database.

If you specify `standby` for `-c` option on both execute system and the standby system, delete of the database is not performed. In such cases, you must manually delete the database. You can check delete targets in KNAN12108-I Message.

Also, when operating a logical host in a non-clustered environment, specify `online`.

`-q`

Specifies that the command is to be executed without user confirmation.

## Return values

|    |                                                                                      |
|----|--------------------------------------------------------------------------------------|
| 0  | Normal termination                                                                   |
| 1  | Abnormal termination                                                                 |
| 3  | Canceled by user (if you enter N/n in KNAN12009-Q Message and Stopped the operation) |
| 20 | Intelligent Integrated Management database not set up                                |

## Log output

This command outputs the following trace log for each process: The integrated trace log is not output.

- File name  
`jimgndbunsetup{1|2}.log#`  
#: {1|2} is a number of faces of the file.
- File size (number of faces)  
256KB (2 faces)
- Output destination
  - In Windows:
    - Physical host and Logical host  
`Manager-path\log\imgndb\`
  - In Linux:
    - Physical host and Logical host  
`/var/opt/jplimm/log/imgndb/`

## Notes

- When executing a command with the `-c` option, do not switch servers during execution. If you switch servers while running, unset them up after the command ends, and then rerun the command.
- The following are precautions when processing is aborted by pressing **Ctrl + C** or **Ctrl + Break** during command execution.
  - Ensure that the `pg_ctl`, `postgres`, and `promscale` processes are not running, run the `jimgndbunsetup` command, and rerun the command. If these processes are running, wait some time for them to end and rerun this command.
  - Processing is aborted, but messages may be output corrupted.
- This command cannot be multiplexed. It cannot be run concurrently with other operational commands in the Intelligent Integrated Administration database.  
For details about Intelligent Integrated Management Database operation command multiplexing execute, see [About multiple execution of the commands related to the Intelligent Integrated Management Database](#).
- If a KNAN12105-E or KNAN12107-E error message is output, or if a KNAN12108-I message is output due to an error, check the directory name in the message and manually delete the data in the corresponding directory.

## Example

- In case of successful completion

```
>jimgndbunsetup
KNAN12035-I Unsetup of the Intelligent Integrated Management Database will be performed.
KNAN12009-Q Do you want to continue processing? (Y/N) :Y
KNAN12036-I Unsetup of the Intelligent Integrated Management Database will now start.
KNAN12020-I Please wait.
KNAN12104-I The Intelligent Integrated Management Database was uninstalled.
KNAN12106-I The data storage directory of the Intelligent Integrated Management Database was deleted.
KNAN12038-I Unsetup of the Intelligent Integrated Management Database ended normally.
```

- In case of abend (when the database is not set up)

```
>jimgndbunsetup
KNAN12035-I Unsetup of the Intelligent Integrated Management Database will be performed.
KNAN12041-E The Intelligent Integrated Management Database is not configured.
```

Function

This command is used to upgrade Intelligent Integrated Management Database and trend data management service.

Execute this command if applicable to the notes described in *7.6.1 Upgrade installation of JP1/Base and JP1/IM - Manager (for Windows)* and *8.6.1 Upgrade installation of JP1/Base and JP1/IM - Manager (for UNIX)* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

In a cluster environment, this command is executed on both the running system and the standby system.

The following shows the execution conditions for this command.

- Intelligent Integrated Management Database and trend data management service are set up and stopped.

Format

```
jimgndbupdate [-h logical-hostname]
```

Execution authority

In Windows: Administrator permissions (If the Windows UAC feature is enabled, the command must be executed from the administrator console.)

In Linux: Superuser permissions

Storage destination directory

For Windows

*Manager-path*\bin\imgndb\

For Linux

/opt/jplimm/bin/imgndb/

Argument

-h *logical-hostname*

Specifies the logical host name of the host where the command is to be executed when operating in a cluster system. For the logical host name, specify the logical host name set in JP1/Base exactly, including case.

Upgrade Intelligent Integrated Management Database (Trend data Management Database) corresponding to the specified logical host. If you are not using a cluster system, you do not need to specify it.

Note that JP1\_DEFAULT cannot be specified for a logical hostname.

Return value

|   |                                                         |
|---|---------------------------------------------------------|
| 0 | Normal completion                                       |
| 1 | Abnormal termination                                    |
| 2 | Abnormal termination (if files or processes may remain) |

## Notes

- If you use the **Ctrl + C** keys or the **Ctrl + Break** keys to abort the process while the command is being executed, the process is interrupted. However, the message may be corrupted and the message may be displayed.
- This command cannot be executed multiple times or concurrently with other Intelligent Integrated Management Database operation commands. For details about multiple execution of Intelligent Integrated Management Database operation commands, see [\*About multiple execution of the commands related to the Intelligent Integrated Management Database.\*](#)

## jimmail (Windows only)

### Function

This command sends an email to a specified email address.

To use the `jimmail` command to send an email, you must set the email environment definition file.

You can execute this command independently regardless of whether the JP1/IM - Manager service is running. The following table describes the functions of JP1/IM - Manager that can be used to send an email.

Table 1–53: JP1/IM - Manager functions used to send an email by using the `jimmail` command

| Function                             | Description                                                                                               |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Automated action                     | An email can be sent by automated action.                                                                 |
| Monitoring action and delay statuses | An email can be sent by using the notification command when an action error is detected.                  |
| Health check                         | An email can be sent by using the notification command when a JP1/IM - Manager process error is detected. |
| Command execution (Command button)   | An email can be sent by pressing a command button.                                                        |

If the maximum length of a command line is exceeded, redefine the email contents so that the command line of the `jimmail` command can fit within the limit.

### Format

```
jimmail [-to destination-email-address[,destination-email-address...]]
        [-s email-subject]
        [-b email-text]
        [-rh logical-host-name]
```

### Execution permission

Administrator permissions (If the Windows UAC feature is enabled, the command is executed from the administrator console.)

### Storage directory

*Console-path\bin\*

### Arguments

`-to destination-email-address [, destination-email-address . . . ]`

This option specifies the email destination address.

A maximum of 20 email addresses can be specified. Note, however, that addresses exceeding the maximum command line length cannot be specified. When specifying multiple email addresses, use a comma (,) as a separator. Any one-byte space or tab between an email address and a comma is ignored. Consecutive commas (,) are treated as a single comma, and commas at the beginning and at the end are ignored. If the same email address is specified more than once, the email message is sent to the specified address only once.

If the number of specified email addresses exceeds the maximum limit, the KAVB8725-E message is output, and the operation terminates abnormally.

You can specify 1 to 256 bytes of characters for the destination email address. One-byte alphanumeric characters, at marks (@), hyphens (-), underscores (\_), and periods (.) can be specified.

This option can be omitted. If you omit this option, processing continues using the email address specified for the `DefaultTo` parameter (default destination email address) in the email environment definition file as the destination. When an email is being processed, the message sent to the email address of the `DefaultTo` parameter is not output.

If the `-to` option is omitted, and no email address is specified for the `DefaultTo` parameter, the `jimmail` command outputs an error message, and the operation terminates abnormally.

If both the `-to` option and the `DefaultTo` parameter are set, the `-to` option takes precedence.

The `jimmail` command does not check if the specified email address is valid.

#### `-s email-subject`

This option specifies the email subject.

You can specify 1 to 512 bytes of characters. The character count is determined by calculating the byte count based on the email character encoding specified by the `Charset` parameter in the email environment definition file. When event or action information is to be inherited, the maximum-length check is performed by calculating the length after `$variable-name` has been replaced. If the calculated length exceeds the maximum length, the value specified for the `MailSubjectCutting` parameter in the email environment definition file determines whether the subject is to be cut to allow the email to be sent.

- When the `MailSubjectCutting` parameter value is `OFF`, the KAVB8708-E message is output, and the command terminates abnormally.
- When the `MailSubjectCutting` parameter value is `ON`, characters for the email subject exceeding 512 bytes are discarded according to the character encoding specified for the `Charset` parameter, and the email is sent. When an email subject exceeds 512 bytes, characters exceeding 512 bytes are discarded. If an email is sent after the exceeding characters in the subject are discarded, the KAVB8724-W message appears before the KAVB8729-I message (indicating the email is sent successfully).

This option can be omitted. If you omit this option, the subject of the email will be a null character ("").

If the email subject contains blank characters, enclose the subject in double-quotation marks ("").

Even if you specify `\n`, a line break is not created in the email subject. If you specify `\n`, it appears as is. Line feed codes and control characters are converted into one-byte spaces.

#### `-b email-text`

This option specifies the email text.

You can specify 1 to 4,096 byte characters for the email text. The number of characters is checked by the number of bytes, according to the character encoding of the email specified by the `Charset` parameter in the email environment definition file. To inherit event or action information, check the maximum length after replacing `$variable-name`.

You can specify 1 to 512 byte characters including linefeed codes for a line. If the characters exceed 512 bytes, insert a linefeed code so that the line will be a maximum of 512 bytes including linefeed codes. When a line exceeds the number, no warning message is output.

This option can be omitted. If you omit this option, the email text will be null characters ("").

If there is no linefeed code at the end of the last line, a linefeed code is inserted.

If the email text contains null characters, enclose and specify the email text by the double-quotation marks ("").

When `\n` is specified in the email text, a new line starts after the linefeed code specified by the `MailNewLine` parameter in the email environment definition file. If the value of the parameter is not `CRLF`, `CR`, or `LF`, `\n` is converted to a single-byte space.

To enter `\n` as a character string, specify it as `\\n`.

`-rh logical-host-name`

When JP1/IM - Manager is used in a cluster, the `-rh` option specifies the email environment definition file to use. With this option, specify if the `jimmail` command uses the email environment definition file on a physical host, or in the shared folder on a logical host.

If you specify this option, the email environment definition file is loaded to a shared folder on the specified logical host, and the email is sent.

If you omit this option, the email environment definition file is loaded to a physical host, and then the email is sent.

Note that if you omit this option, the logical hostname specified for the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you do not use JP1/IM - Manager in a cluster, it is not necessary to specify this option.

## Note

- Specify the subject and text of the email specified in the command line within the range of character encoding defined in the email environment definition file. For details about the email environment definition file, see [Email environment definition file \(jimmail.conf\)](#) in *Chapter 2. Definition Files*.
- The following control characters included in the event information passed to an email sent by the `jimmail` command (executed as an automated action or by clicking a command button) are converted to a single-byte space (0x20):  
0x01 to 0x1F excluding 0x09 (tab), and 0x7F  
For example, if the message obtained by `$EVMSG` includes 0x0A (line feed code), 0x0A is converted to 0x20 (single-byte space).

## Return values

| Return value | Description                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 0            | Normal termination                                                                                                                |
| 1            | Argument error                                                                                                                    |
| 2            | Destination email address is not specified.                                                                                       |
| 3            | Error while reading the email environment definition file                                                                         |
| 4            | Format error of the email environment definition file<br>(Invalid setting value, essential item not specified, invalid parameter) |
| 5            | A timeout error occurred while connecting to the SMTP server                                                                      |
| 6            | SMTP server rejected the login                                                                                                    |
| 7            | Connection to the SMTP server could not be established                                                                            |
| 8            | A timeout error occurred while connecting to the POP3 server                                                                      |
| 9            | POP3 server rejected the login                                                                                                    |
| 10           | Connection to the POP3 server could not be established                                                                            |
| 11           | Sending an email failed                                                                                                           |
| 12           | Insufficient memory                                                                                                               |
| 13           | Execution permission error                                                                                                        |
| 255          | Other errors                                                                                                                      |

## Example

The following is an email notification example from the manager host (jplimhost001) to the system administrator (user@hitachi.com) about a failure on the monitored host (gyoumu001) through automated action, and the contents of the email to be sent:

```
jimmail.exe -to user@hitachi.com -s "[severity:$EVSEV] Failure notification" -b "A failure occurred on the business server. \n---\n event DB serial number=$EVSEQNO\nevent-occurrence-date-and-time=$EVDATE $EVTIME\nEvent ID=$EVID\nBASE\nSeverity=$EVSEV\nProduct name=$EV\"PRODUCT_NAME\"\nMessage=$EVMSG\n---\nFrom:IM-M host ($ACTHOST) "
```

Example of email notification:

|                  |                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# jimmailpasswd (Windows only)

---

## Function

Sets the POP before SMTP or SMTP-AUTH authentication password in the email environment definition file. This command can be executed independently regardless of the running status of the JP1/IM - Manager service.

Before executing this command, set the following items in the email environment definition file:

- Specify POP or SMTP for the `AuthMethod` parameter.
- Specify the authentication account name for the `AuthUser` parameter.

If you execute this command without specifying these parameters, the KAVB8714-E or KAVB8736-E message is output, and the operation terminates abnormally.

## Format

```
jimmailpasswd {-p new-authentication-password | -d}  
               [-rh logical-host-name]
```

## Execution permission

Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console).

## Storage directory

*Console-path*\bin\

## Arguments

**-p** *new-authentication-password*

This option sets the authentication password when POP before SMTP or SMTP-AUTH authentication is used to connect to an email server in the email environment definition file.

Specify an authentication password from 1 to 127 bytes for the argument of the option. The authentication password of the argument cannot be omitted.

Permitted characters are one-byte characters other than control characters (0x00 to 0x1F, and 0x7F to 0x9F). Multi-byte characters cannot be specified. The password is case sensitive.

If you omit a password for the argument of the option, the KAVB8704-E message is output, and the operation terminates abnormally.

**-d**

This option deletes an authentication password from the email environment definition file. If you execute this command with this option specified, the setting value for the `AuthPassword` parameter (password section) in the email environment definition file is deleted.

The **-d** option cannot be specified with the **-p** option.

**-rh** *logical-host-name*

When JP1/IM - Manager is used in a cluster, the **-rh** option specifies the email environment definition file to use. With this option, specify if the `jimmail` command uses the email environment definition file on a physical host, or in the shared folder on a logical host.

When you specify this option, an authentication password is set in the email environment definition file in a shared folder on the specified logical host.

If you omit this option, an authentication password is set in the email environment definition file on a physical host.

Note that if you omit its option, the logical host name specified for the `JP1_HOSTNAME` environment variable is assumed. If the `JP1_HOSTNAME` environment variable is not specified, the physical host name is assumed. If you do not use JP1/IM - Manager in a cluster, you do not need to specify this option.

## Example 1

Specify the authentication password ABCD in the email environment definition file:

```
$ jimmailpasswd -p ABCD
KAVB8731-I Command (jimmailpasswd) started.
KAVB8730-I Password was set successfully.
KAVB8732-I Command (jimmailpasswd) ended normally.
```

## Example 2

Set the authentication password ABCD in the email environment definition file on the logical host (`ronri`):

```
$ jimmailpasswd -p ABCD -rh ronri
KAVB8731-I Command (jimmailpasswd) stated.
KAVB8730-I Password was set successfully.
KAVB8732-I Command (jimmailpasswd) ended normally.
```

## Example 3

Delete the authentication password from the email environment definition file:

```
$ jimmailpasswd -d
KAVB8731-I Command (jimmailpasswd) started.
KAVB8734-I Password was deleted successfully.
KAVB8732-I Command (jimmailpasswd) ended normally.
```

## Function

This command counts the number of nodes managed by JP1/IM - Manager. This command also outputs a file that contains a list of managed nodes.

This command can be executed regardless of whether JP1/IM - Manager is running.

The nodes that this command can count (as nodes managed by JP1/IM - Manager) are JP1/Base on the host defined in the configuration definition information and remotely monitored hosts.

Note that JP1/Base installed on a host that is not defined in the configuration definition information is not counted as a managed node. JP1/Base on such a host must be counted by the user manually.

## Format

```
jimnodecount[ -h logical-host-name | -m]  
               [ -o output-file-name]
```

## Execution permission

In Windows: Administrator permissions

In UNIX: Superuser permissions

## Storage directory

In Windows:

*Manager-path*\bin\

In UNIX:

/opt/jplimm/bin/

## Arguments

**-h** *logical-host-name*

If JP1/IM - Manager is operating in a cluster system, use this option to specify which type of host (physical or logical) the nodes to be counted by the `jimnodecount` command are managed by.

If the **-h** option is specified, the command counts the nodes managed by the specified logical host.

If the **-h** option is not specified, the command counts the nodes managed by the logical host specified in the `JP1_HOSTNAME` environment variable. If no logical host name is specified in that environment variable, the command counts the nodes managed by the physical node.

If JP1/IM - Manager is not operating in a cluster system, you do not need to specify this option.

**-m**

If JP1/IM - Manager is operating in a cluster system, use this option to specify whether the `jimnodecount` command counts the total number of nodes managed by the physical host and logical host.

If the **-m** option is specified, the command counts the number of all managed nodes.

If the **-m** option is not specified, the command counts the number of nodes managed by the logical host specified in the `JP1_HOSTNAME` environment variable. If no logical host name is specified in that environment variable, the command counts the number of nodes managed by the physical host.

### -o *output-file-name*

This option specifies the managed-node list file to which a list of managed nodes is to be output. If the specified file already exists, the contents of the existing file are overwritten.

The output file name can be specified as a relative path or absolute path. If a relative path is used to specify the output file name, the directory where the `jimnodecount` command is executed is used as the base of the relative path. If you specify a file whose name begins with a hyphen (-), to distinguish the file name from an option name, use a relative path that begins with the current directory (for example, `./-foo`) or an absolute path. Note that the length of the file name you specify must not exceed 250 bytes including the length of the path.

Network paths cannot be specified as the output file name.

Also note that in Windows, the file name you specify must not include the following character strings:

- Colon (:), question mark (?), double quotation mark ("), left angle bracket (<), right angle bracket (>), and vertical bar(|)
- A string that completely matches one of the following strings (ignoring case): CON, PRN, AUX, NUL, COM1, COM2, COM3, COM4, COM5, COM6, COM7, COM8, COM9, LPT1, LPT2, LPT3, LPT4, LPT5, LPT6, LPT7, LPT8, or LPT9

## Output format

When you execute the `jimnodecount` command, the number of managed nodes is output in the format below.

Note that if an error occurs during execution of the command, the number of managed nodes is not output.

```
number-of-managed-nodes
```

## Note

In a cluster system configuration in which JP1/IM - Managers on multiple logical hosts manage the same host as a managed node, each logical host is counted as a single host by the `jimnodecount -m` command. In this case, reduce the number of managed nodes appropriately:

## Return values

|     |                                                                                                                                                                 |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Normal termination                                                                                                                                              |
| 43  | The <code>jimnodecount</code> command was executed while the remote configurations were being applied or the <code>jcfimport</code> command was being executed. |
| 84  | Argument error                                                                                                                                                  |
| 85  | Execution permission error                                                                                                                                      |
| 127 | Other error                                                                                                                                                     |

## Format of the managed-node list file

The following describes the format of the managed-node list file. The numbers at the beginning of each line (1 to 12) indicate line numbers, which are not output in the actual file.

```
1  output-time
2  The number of managed nodes : number-of-managed-nodes
3  M   /manager-host-name
4  B   /manager-host-name/host-name-for-JP1/Base-on-host-defined-in-configuration-definition-information
5  R   /manager-host-name/name-of-remotely-monitored-host
```

```

6 BR /manager-host-name/host-name-for-JP1/Base-on-remotely-monitored-host-
defined-in-configuration-definition-information
7 B /manager-host-name/site-manager-host-name
8 B /manager-host-name/site-manager-host-name/host-name-for-JP1/Base-on-h
ost-defined-in-configuration-definition-information
9 R /manager-host-name/site-manager-host-name/name-of-remotely-monitored-
host
10 BR /manager-host-name/site-manager-host-name/host-name-for-JP1/Base-on-r
emotely-monitored-host-defined-in-configuration-definition-information
11 B /manager-host-name/relay-manager-host-name
12 B /manager-host-name/relay-manager-host-name/host-name-for-JP1/Base-on-
host-defined-in-configuration-definition-information

```

Lines 2 to 12 are the managed-node block, which consists of the number of managed nodes on line 2 and the managed-node list on lines 3 to 12.

## Description of the elements output to the managed-node list file

### output-time

The time that the `jimnodecount` command was executed and the managed-node list file was output is indicated here.

```
YYYY/MM/DD hh:mm:ss
```

(YYYY: year, MM: month, DD: day, hh: hour, mm: minute, ss: second)

### Managed-node block

The elements of a managed-node block are as follows:

- The number of managed nodes : *number-of-managed-nodes*  
The number of managed nodes counted by the command is indicated here.

- Managed-node list

*type-of-managed-node/host-name* [ */host-name...* ]

The strings output for *type-of-managed-node* are described below.

| Type | Description                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MΔ Δ | Manager host on which the <code>jimnodecount</code> command was executed                                                                                               |
| BΔ Δ | JP1/Base on a host that is defined in the configuration definition information and is not the Manager host on which the <code>jimnodecount</code> command was executed |
| RΔ Δ | Remotely monitored host                                                                                                                                                |
| BΔ   | JP1/Base on a remotely monitored host that is defined in the configuration definition information                                                                      |

Legend: Δ: A single-byte space

The managed-node block output format differs depending on whether the `-m` option is specified.

If the `-m` option is not specified:

Only one managed-node block is output.

The following shows an example of the file output if the `-m` option is not specified.

| Integrated manager    | Site manager | Agent  |
|-----------------------|--------------|--------|
| Physical host (kanri) | tokyo        | jplag1 |
|                       | osaka        | rhost1 |

| Integrated manager | Site manager | Agent  |
|--------------------|--------------|--------|
|                    |              | jplag2 |

```

2016/04/28 09:00:00
The number of managed nodes : 6
M /admin
B /admin/tokyo
B /admin/tokyo/jplag1
B /admin/osaka
R /admin/osaka/rhost1
BR /admin/osaka/jplag2

```

If the `-m` option is specified:

Multiple managed-node blocks are output. The managed-node block for the physical host is output before the managed-node blocks for logical hosts. The managed-node blocks for logical hosts are output in the ascending order of logical host names.

The following shows an example of the file output if the `-m` option is specified.

| Integrated manager     | Site manager | Agent  |
|------------------------|--------------|--------|
| Physical host (admin)  | tokyo        | jplag1 |
| Logical host (adminL1) | osakaA       | jplag2 |
|                        | osakaB       | jplag3 |
| Logical host (adminL2) | nagoyaA      | jplag4 |
| Logical host (adminL3) | nagoyaB      | jplag5 |

```

2016/11/26 09:00:00
The number of managed nodes : 3
M /admin
B /admin/tokyo
B /admin/tokyo/jplag1
The number of managed nodes : 5
M /adminL1
B /adminL1/osakaA
B /adminL1/osakaA/jplag2
B /adminL1/osakaB
B /adminL1/osakaB/jplag3
KAVB8201-E-or-KAVB8202-E-message-text#
The number of managed nodes : 3
M /adminL3
B /adminL3/nagoyaB
B /adminL3/nagoyaB/jplag5

```

#: Because the command failed to count the number of nodes managed by logical host adminL2, a message (KAVB8201-E or KAVB8202-E) was output. For details about the message, see the *JP1/Integrated Management 3 - Manager Messages*.

## jp1cc\_setup (UNIX only)

---

### Function

This command sets up an operating environment for JP1/IM - Manager (Central Console).

Use this command only after you have uninstalled JP1/Base on a computer where both JP1/IM - Manager and JP1/Base were installed and you have then re-installed JP1/Base. When you use Hitachi Program Product Installer to perform a new installation or an overwrite installation of JP1/IM - Manager, there is no need to execute this command.

### Format

```
jp1cc_setup
```

### Execution permission

Superuser permissions

### Storage directory

/opt/jp1cons/bin/

# jp1cshaverup.bat (Windows only)

## Function

This command upgrades a logical host environment that was set up for JP1/IM - Manager (Central Scope). Use this command after you have upgraded your JP1/IM - Manager (Central Scope) in a logical host environment.

## Format

```
jp1cshaverup.bat -h logical-host-name
                  [-w work-directory]
```

## Execution permission

Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

## Storage directory

*Scope-path*\bin\

Note: This command is not included in JP1/IM - Manager for Linux.

## Arguments

-h *logical-host-name*

Specifies the name of the logical host that is to be upgraded. If this option is omitted, an error results.

-w *work-directory*

Specifies the full path of a work folder that will be used to upgrade the logical host environment for JP1/IM - Manager (Central Scope). If the path contains a space, enclose the entire path in double-quotation marks ("").

If this option is omitted, *Scope-path*\tmp\ is assumed.

## Notes

- You must terminate JP1/IM - Manager before you execute this command. An error results if this command is executed while JP1/IM - Manager is running.
- Once the jp1cshaverup.bat command has been executed, JP1/IM - Manager (Central Scope) runs under the new version that has been installed, and you can no longer log in from the Monitoring Tree (Editing) window of JP1/IM - View version 08-01 or earlier.
- Return values

|    |                                           |
|----|-------------------------------------------|
| 0  | Normal termination                        |
| 1  | Specified logical host name was not found |
| 2  | Argument error                            |
| 4  | No permission to execute the command      |
| 12 | Insufficient memory                       |
| 13 | Insufficient disk capacity                |
| 31 | Database initialization error             |

|    |                                                                               |
|----|-------------------------------------------------------------------------------|
| 32 | Data access error                                                             |
| 42 | A service is running                                                          |
| 45 | An attempt was made to execute the command on the new version of the database |
| 99 | Other error                                                                   |

## Examples

Upgrade the logicalhost logical host environment for the JPI/IM - Manager (Central Scope) instance that is running under version 08-01; use the C:\temp\ work folder:

```
jplcshaverup -h logicalhost -w C:\temp
```

## Example output

```
The upgrade processing started.
KAVB7750-I Upgrading of the database version has finished.
KAVB7624-I The jcsdbconvert command finished successfully.
The upgrade processing ends successfully.
```

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## jp1cc\_setup\_cluster (UNIX only)

---

### Function

This command sets up an operating environment for a logical host of JP1/IM - Manager (Central Console). Use this command for environment setup in a cluster system.

Set up the environment for the primary node first, and then set up the standby node.

In the environment setup for the primary node, you must specify the logical host name and shared directory name. When you execute this command, information such as definition files is copied to the specified shared directory; therefore, you must have already made the shared disk available for use.

In the environment setup for the standby node, specify only the logical host name. The operating environment is set up on the basis of the information specified for the executing node.

Before you start setting up an environment for the secondary node, you must use the `jbsgetcnf` and `jbssetcnf` commands of JP1/Base to copy to the standby node the common definition information set at the executing node.

When you execute this command, the socket binding method used for TCP/IP communication is changed to the IP binding method. The command changes this setting for the physical host and for the logical host that is to be created. For details about the socket binding method used for TCP/IP communication, see the documentation for the applicable OS.

### Format

```
jp1cc_setup_cluster -h logical-host-name
                    [-d shared-directory-name]
```

### Execution permission

Superuser permissions

### Storage directory

/opt/jp1cons/bin/

### Arguments

-h *logical-host-name*

Specifies a host name for the logical host whose environment is to be set up. The permitted length is from 1 to 63 bytes characters.

Set the specified logical host name in the `hosts` file and in the name server to enable TCP/IP communication.

-d *shared-directory-name*

Specifies a shared directory for storing the information that is to be inherited during node switching. Specify a directory on the shared disk. The permitted length is from 1 to 165 bytes characters.

The command creates the directories listed below in the specified shared directory and then copies definition files from `/etc/opt/jp1cons/conf/`. Appropriate permissions are set for the created directories. Do not change the set permissions of the directories.

Table 1–54: Directories created by the `jp1cc_setup_cluster` command

| Type of files to be stored | Directory                                        |
|----------------------------|--------------------------------------------------|
| Definition files           | <i>shared-directory-name</i> /jp1cons/conf/      |
| Log files                  | <i>shared-directory-name</i> /jp1cons/log/       |
| Temporary files            | <i>shared-directory-name</i> /jp1cons/tmp/       |
| History files <sup>#</sup> | <i>shared-directory-name</i> /jp1cons/operation/ |

<sup>#</sup>: The processing of the correlation event generation function is output as history data.

Change the definition files, if necessary.

### Notes

- You must set a logical host for each node.
- You must make the shared disk available for use before you set up an environment for the primary node by executing the `jp1cc_setup_cluster` command.

### Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

### Examples

Set up an environment with the following conditions:

Logical host name: lnode0  
Shared disk: /shdisk/lnode0

- Setting up the logical host environment at the primary server

jp1cc\_setup\_cluster -h lnode0 -d /shdisk/lnode0

- Setting up the logical host environment at the secondary server

jp1cc\_setup\_cluster -h lnode0

## jp1cf\_setup (UNIX only)

---

### Function

This command sets up an operating environment for the IM Configuration Management process of JP1/IM - Manager.

Use this command only after you have uninstalled JP1/Base on a computer where both JP1/IM - Manager and JP1/Base were installed and you have then re-installed JP1/Base.

### Format

```
jp1cf_setup
```

### Execution permission

Superuser permissions

### Storage directory

/opt/jp1imm/bin/imcf

### Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## jp1cf\_setup\_cluster (UNIX only)

### Function

This command sets up an environment for IM Configuration Management when you are operating in a cluster system.

This cluster setup for IM Configuration Management applies to both the primary node and the standby node of the logical host. When the `-d` option is specified, the command sets up the primary node; when the `-d` option is omitted, the command sets up the secondary node.

The following table lists and describes the settings for the primary and secondary nodes.

Table 1–55: Settings for the primary and secondary nodes

| Host where command is executed | Setting item                                                                                           | Overview of setting                                                                                                                                                                                                                                                       |
|--------------------------------|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Primary node                   | Common definition settings for the logical host                                                        | Use the <code>jbsgetcnf</code> and <code>jbssetcnf</code> commands to set the common definitions of IM Configuration Management for the physical host to also be the common definitions for the logical host. Some information (such as directory names) must be changed. |
|                                | Creating the shared directory                                                                          | Create the required directories under the shared directory.                                                                                                                                                                                                               |
|                                | Copying the definition files                                                                           | Copy the definition files from <code>/opt/jplimm/conf/imcf</code> to the directories under <i>shared-directory</i> / <code>jplimm/conf/imcf</code> .                                                                                                                      |
|                                | Setting startup of IM Configuration Management for the instance of Central Console on the logical host | Use the <code>jcoimdef</code> command to set IM Configuration Management Service to start according to process management of the instance of Central Console on the logical host.                                                                                         |
|                                | Changing the communication method for IM Configuration Management on the physical host                 | Change the communication method for IM Configuration Management on the physical host to the IP binding method.                                                                                                                                                            |
| Secondary node                 | Changing the communication method on the physical host                                                 | Same as above                                                                                                                                                                                                                                                             |

### Setting the common definitions

Cluster setup of IM Configuration Management sets the values shown below in the common definitions for the logical host.

Table 1–56: Common definitions for the logical host

| Path                               | Key name          | Setting                                                      |
|------------------------------------|-------------------|--------------------------------------------------------------|
| <i>logical-host-name</i> \JP1CONF\ | JP1CONFIG_CONFDIR | <i>shared-directory-name</i> / <code>jplimm/conf/imcf</code> |
|                                    | JP1CONFIG_TMPDIR  | <i>shared-directory-name</i> / <code>jplimm/tmp</code>       |
|                                    | JP1CONFIG_LOGDIR  | <i>shared-directory-name</i> / <code>jplimm/log/imcf</code>  |
|                                    | JP1CONFIG_DATADIR | <i>shared-directory-name</i> / <code>jplimm/data/imcf</code> |
|                                    | JP1_BIND_ADDR     | IP                                                           |

### Creating the shared directory

Cluster setup of IM Configuration Management creates the directories shown below. Appropriate permissions are set for the created directories. Do not change the set permissions of the directories.

Table 1–57: Directories created when the `jp1cf_setup_cluster` command is executed

| Type of files to be stored                 | Directory                                      |
|--------------------------------------------|------------------------------------------------|
| Definition files                           | <i>shared-directory-name</i> /jplimm/conf/imcf |
| Log files                                  | <i>shared-directory-name</i> /jplimm/log/imcf  |
| Temporary files                            | <i>shared-directory-name</i> /jplimm/tmp       |
| Data for the system hierarchy and profiles | <i>shared-directory-name</i> /jplimm/data/imcf |

Setting startup of IM Configuration Management for the instance of Central Console on the logical host

Execute the `jcoimdef` command to add the IM Configuration Management startup settings to the process management of the instance of Central Console on the same logical host.

Changing the communication method for IM Configuration Management on the physical host

Cluster setup of IM Configuration Management changes the communication method for the physical host to the IP binding method by changing the value of `JP1_BIND_ADDR` under the `JP1_DEFAULT\JP1CONFIG\ common` definition to `IP`.

## Format

```
jp1cf_setup_cluster  -h logical-host-name
                    [-d shared-directory-name]
```

## Execution permission

Superuser permissions

## Storage directory

/opt/jplimm/bin/imcf

## Arguments

- `-h logical-host-name`  
When you are operating in a cluster system, this option specifies the logical host name of the host where the command is executed. The command reorganizes the database for the specified logical host. The permitted length is from 1 to 63 bytes characters. If this option is omitted, an error results.
- `-d shared-directory-name`  
Specifies the shared directory for the logical host in order to set up the primary node. When this option is omitted, the command sets up the secondary node. The permitted length is from 1 to 165 bytes characters.

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## Notes

- When you set up the primary node, you must mount the shared disk in order to copy the definition files to the shared directory and create a monitoring object database.
- You must set up a logical host for each node.

- When you execute this command, the socket binding method used for TCP/IP communication is changed to the IP binding method. The command changes this setting for the physical host and for the logical host that is to be created. For details about the socket binding method used for TCP/IP communication, see the documentation for the applicable OS.

## jp1cfhassetup (Windows only)

---

### Function

This command sets up an environment for IM Configuration Management when you are operating in a cluster system.

Before you execute this command, you must set up the logical host of JP1/Base.

When you execute this command, the socket binding method used for TCP/IP communication is changed to the IP binding method. The command changes this setting for the physical host and for the logical host that is to be created. For details about the socket binding method used for TCP/IP communication, see the documentation for the applicable OS.

### Format

```
jp1cfhassetup
```

### Execution permission

Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

### Storage directory

*Manager-path*\bin\imcf\

### Notes

- If you want to execute the `jp1cfhassetup` command, execute the `jp1cohassetup` command first.
- Set a logical host for each node.
- You must have set up the logical host for JP1/Base beforehand. For details about how to set up JP1/Base, see the *JP1/Base User's Guide*.

## jp1cohasetup (Windows only)

---

### Function

This command displays the Settings for Central Console Cluster System dialog box, which is used to set up an operating environment for the logical host of JP1/IM - Manager (Central Console). Use this command to set up an environment for JP1/IM - Manager (Central Console) in a cluster system.

When you execute this command, the socket binding method used for TCP/IP communication is changed to the IP binding method. The command changes this setting for the physical host and for the logical host that is to be created. For details about the socket binding method used for TCP/IP communication, see the documentation for the applicable OS.

### Format

```
jp1cohasetup
```

### Execution permission

Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

### Storage directory

*Console-path\bin\*

### Notes

- Use this command to set up an environment for JP1/IM - Manager (Central Console) in a cluster system. Use the `jp1cshasetup` command to set up an environment for JP1/IM - Manager (Central Scope).
- Set a logical host for each node.
- You must have set up the logical host for JP1/Base beforehand. For details about how to set up JP1/Base, see the *JP1/Base User's Guide*.

Function

This command upgrades a logical host environment that was set up for JP1/IM - Manager. Use this command after you have upgraded your JP1/IM - Manager in a logical host environment.

Format

```
jp1cohaverup -h logical-host-name
```

Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In UNIX: Superuser permissions

Storage directory

In Windows:  
*Console-path*\bin\  
In UNIX:  
/opt/jp1cons/bin/

Arguments

-h *logical-host-name*  
Specifies the name of the logical host to be upgraded. If this option is omitted, an error results.

Notes

- You must terminate JP1/IM - Manager before you execute this command. An error results if this command is executed while JP1/IM - Manager is running.
- Execute this command only on the primary host. Make sure that the shared disk is mounted when the command executes. Do not execute this command on the secondary host.
- After you have executed this command, you must back up the common definition information from the primary host, copy the backup common definition information to the secondary host, and then use the `jbssetcnf` command to set the information.
- If you have installed a corrected edition of the same version by overwriting, there is no need to execute this command.

Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

Examples

Upgrade logical host `host01`:

```
jplcohaverup -h host01
```

## Example output

```
jplcohaverup -h host01  
KAVB9101-I The upgrading of the logical host environment will now start.  
KAVB9102-I The upgrading of the logical host environment has finished.
```

# jp1cs\_setup (UNIX only)

---

## Function

This command sets up an operating environment for JP1/IM - Manager (Central Scope).

Use this command only after you have uninstalled JP1/Base on a computer where both JP1/IM - Manager and JP1/Base were installed and you have then re-installed JP1/Base. When you use Hitachi Program Product Installer to perform a new installation or an overwrite installation of JP1/IM - Manager, there is no need to execute this command.

You must terminate JP1/IM - Manager before you use this command.

## Format

```
jp1cs_setup
```

## Execution permission

Superuser permissions

## Storage directory

/opt/jp1scope/bin/

## Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

## jp1cs\_setup\_cluster (UNIX only)

---

### Function

This command sets up an operating environment for a logical host of JP1/IM - Manager (Central Scope). Use this command for environment setup in a cluster system.

Set up the environment for the primary node first, and then set up the standby node.

In the environment setup for the primary node, you must specify the logical host name and shared directory name. When you execute the command, information such as definition files is copied to the specified shared directory; therefore, you must have already made the shared disk available for use.

In the environment setup for the standby node, specify only the logical host name. The operating environment is set up based on the information specified for the executing node.

Before you start setting up an environment for the secondary node, you must use the `jbsgetcnf` and `jbssetcnf` commands of JP1/Base to copy to the standby node the common definition information set at the executing node.

Before you use this command, terminate JP1/IM - Manager.

When you execute this command, the socket binding method used for TCP/IP communication is changed to the IP binding method. The command changes this setting for the physical host and for the logical host that is to be created. For details about the socket binding method used for TCP/IP communication, see the documentation for the applicable OS.

### Format

```
jp1cs_setup_cluster -h logical-host-name
                    [-d shared-directory-name]
```

### Execution permission

Superuser permissions

### Storage directory

/opt/jp1scope/bin/

### Arguments

-h *logical-host-name*

Specifies a host name for the logical host whose environment is to be set up. The permitted length is from 1 to 63 bytes characters.

Set the specified logical host name in the `hosts` file and in the name server to enable TCP/IP communication.

-d *shared-directory-name*

Specifies a shared directory for storing the information that is to be inherited during node switching. Specify a directory on the shared disk. The permitted length is from 1 to 165 bytes characters.

The command creates the directories listed below in the specified shared directory and then copies definition files from `/etc/opt/jp1scope/conf/`. Appropriate permissions are set for the created directories. Do not change the set permissions of the directories.

Table 1–58: Directories created by the `jp1cs_setup_cluster` command

| Type of files to be stored | Directory                                        |
|----------------------------|--------------------------------------------------|
| Definition files           | <i>shared-directory-name</i> /jp1scope/conf/     |
| Log files                  | <i>shared-directory-name</i> /jp1scope/log/      |
| Temporary files            | <i>shared-directory-name</i> /jp1scope/tmp/      |
| Database information       | <i>shared-directory-name</i> /jp1scope/database/ |

Change the definition files, if necessary.

### Notes

- You must set a logical host for each node.
- You must make the shared disk available for use before you set up an environment for the primary node by executing the `jp1cs_setup_cluster` command.

### Return values

|   |                      |
|---|----------------------|
| 0 | Normal termination   |
| 1 | Abnormal termination |

### Examples

Set up an environment with the following conditions:

Logical host name: lnode0  
Shared disk: shdsk/lnode0

- Setting up the logical host environment at the primary server

jp1cs\_setup\_cluster -h lnode0 -d /shdsk/lnode0

- Setting up the logical host environment at the secondary server

jp1cs\_setup\_cluster -h lnode0

## jp1cshasetup (Windows only)

---

### Function

This command displays the Settings for Central Scope Cluster System dialog box that is used to set up an operating environment for the logical host of JP1/IM - Manager (Central Scope). Use this command to set up an environment for JP1/IM - Manager (Central Scope) in a cluster system.

When you execute this command, the socket binding method used for TCP/IP communication is changed to the IP binding method. The command changes this setting for the physical host and for the logical host that is to be created. For details about the socket binding method used for TCP/IP communication, see the documentation for the applicable OS.

### Format

```
jp1cshasetup
```

### Execution permission

Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

### Storage directory

*Scope-path*\bin\

### Notes

- Use this command to set up an environment for JP1/IM - Manager (Central Scope) in a cluster system. Use the `jp1cohasetup` command to set up an environment for JP1/IM - Manager (Central Console).
- Set a logical host for each node.
- You must have set up the logical host for JP1/Base beforehand. For details about how to set up JP1/Base, see the chapter that describes setup for operation in a cluster system in the *JP1/Base User's Guide*.  
You must have already set up a logical host for JP1/IM - Manager (Central Console).

# jp1cshaverup (UNIX only)

## Function

This command upgrades a logical host environment that was set up for JP1/IM - Manager (Central Scope). Use this command after you have upgraded your JP1/IM - Manager (Central Scope) in a logical host environment.

## Format

```
jp1cshaverup -h logical-host-name
               [-w work-directory]
```

## Execution permission

Superuser permissions

## Storage directory

/opt/jp1scope/bin/

## Arguments

-h *logical-host-name*

Specifies the name of the logical host to be upgraded. If this option is omitted, an error results.

-w *work-directory*

Specifies the full path of a work directory that will be used to upgrade the logical host environment for JP1/IM - Manager (Central Scope).

If this option is omitted, /opt/jp1scope/tmp/ is assumed.

## Notes

- You must terminate JP1/IM - Manager before you execute this command. An error results if this command is executed while JP1/IM - Manager is running.
- Once the `jp1cshaverup` command has been executed, JP1/IM - Manager (Central Scope) runs under the new version that has been installed, and you can no longer log in from the Monitoring Tree (Editing) window of JP1/IM - View version 08-01 or earlier.

## Return values

|    |                                           |
|----|-------------------------------------------|
| 0  | Normal termination                        |
| 1  | Specified logical host name was not found |
| 2  | Argument error                            |
| 4  | No permission to execute the command      |
| 12 | Insufficient memory                       |
| 13 | Insufficient disk capacity                |
| 31 | Database initialization error             |
| 32 | Data access error                         |
| 42 | A service is running                      |

|    |                                                                               |
|----|-------------------------------------------------------------------------------|
| 45 | An attempt was made to execute the command on the new version of the database |
| 99 | Other error                                                                   |

## Examples

Upgrade the `logicalhost` logical host environment for the JP1/IM - Manager (Central Scope) instance that is running under version 08-01; use the `/temp/` work directory:

```
jplcshaverup -h logicalhost -w /temp
```

## Example output

```
The upgrade processing started.
KAVB7750-I Upgrading of the database version has finished.
KAVB7624-I The jcsdbconvert command finished successfully.
The upgrade processing ends successfully.
```

# jp1csverup (UNIX only)

## Function

This command upgrades a physical host environment that has been set up for JP1/IM - Manager (Central Scope) under version 08-01 or earlier. Use this command after you have upgraded your JP1/IM - Manager (Central Scope) from version 08-01 or earlier.

You must execute this command in order to use the functions of a new version of JP1/IM - Manager (Central Scope) that has been installed. However, if you want to use only the functions supported by version 08-01 or earlier, do not execute this command.

## Format

```
jp1csverup [-w work-directory]
```

## Execution permission

Superuser permissions

## Storage directory

/opt/jp1scope/bin/

Note: This command is not included in JP1/IM - Manager for Linux.

## Arguments

- `-w work-directory`  
Specifies the full path of a work directory that will be used to upgrade the physical host environment for JP1/IM - Manager (Central Scope).  
If this option is omitted, /opt/jp1scope/tmp/ is assumed.

## Notes

- You must terminate JP1/IM - Manager before you execute this command. An error results if this command is executed while JP1/IM - Manager is running.
- Before you execute this command, check the available disk space. To execute this command, you need free space equivalent to the size of the monitoring object database. The monitoring object database consists of all data in the following directory:  
/var/opt/jp1scope/database/jcsdb/
- Once the jp1csverup command has been executed, JP1/IM - Manager (Central Scope) runs under the new version that has been installed, and you can no longer log in from the Monitoring Tree (Editing) window of JP1/IM - View version 08-01 or earlier.

## Return values

|    |                                      |
|----|--------------------------------------|
| 0  | Normal termination                   |
| 2  | Argument error                       |
| 4  | No permission to execute the command |
| 12 | Insufficient memory                  |

|    |                                                                               |
|----|-------------------------------------------------------------------------------|
| 13 | Insufficient disk capacity                                                    |
| 31 | Database initialization error                                                 |
| 32 | Data access error                                                             |
| 42 | A service is running                                                          |
| 45 | An attempt was made to execute the command on the new version of the database |
| 99 | Other error                                                                   |

## Examples

Upgrade the physical host environment for the JP1/IM - Manager (Central Scope) that is running under version 08-01; use the /temp/ work directory:

```
jplcsverup -w /temp
```

## Example output

```
The upgrade processing started.
KAVB7750-I Upgrading of the database version has finished.
KAVB7624-I The jcsdbconvert command finished successfully.
The upgrade processing ends successfully.
```

# jp1csverup.bat (Windows only)

## Function

This command upgrades a physical host environment that has been set up for JP1/IM - Manager (Central Scope) under version 08-01 or earlier. Use this command after you have upgraded your JP1/IM - Manager (Central Scope) from version 08-01 or earlier.

You must execute this command in order to use the functions of a new version of JP1/IM - Manager (Central Scope) that has been installed. However, if you want to use only the functions supported by version 08-01 or earlier, do not execute this command.

## Format

```
jp1csverup.bat [-w work-directory]
```

## Execution permission

Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

## Storage directory

*Scope-path\bin\*

## Arguments

*-w work-directory*

Specifies the full path of a work folder that will be used to upgrade the physical host environment for JP1/IM - Manager (Central Scope). If the path contains a space, enclose the entire path in double-quotation marks ("").

If this option is omitted, *Scope-path\tmp\* is assumed.

## Notes

- You must terminate JP1/IM - Manager before you execute this command. An error results if this command is executed while JP1/IM - Manager is running.
- Before you execute this command, check the available disk space. To execute this command, you need free space equivalent to the size of the monitoring object database. The monitoring object database consists of all data in the following folder:  
*Scope-path\database\jcsdb\*
- Once the `jp1csverup.bat` command has been executed, JP1/IM - Manager (Central Scope) runs under the new version that has been installed, and you can no longer log in from the Monitoring Tree (Editing) window of JP1/IM - View version 08-01 or earlier.

## Return values

|    |                                      |
|----|--------------------------------------|
| 0  | Normal termination                   |
| 2  | Argument error                       |
| 4  | No permission to execute the command |
| 12 | Insufficient memory                  |

|    |                                                                               |
|----|-------------------------------------------------------------------------------|
| 13 | Insufficient disk capacity                                                    |
| 31 | Database initialization error                                                 |
| 32 | Data access error                                                             |
| 42 | A service is running                                                          |
| 45 | An attempt was made to execute the command on the new version of the database |
| 99 | Other error                                                                   |

## Examples

Upgrade the physical host environment for the JP1/IM - Manager (Central Scope) that is running under version 08-01; use the C:\temp work folder:

```
jplcsverup -w C:\temp
```

## Example output

```
The upgrade processing started.
KAVB7750-I Upgrading of the database version has finished.
KAVB7624-I The jcsdbconvert command finished successfully.
The upgrade processing ends successfully.
```

# jpc\_service

---

## Function

This command turns Setup Enable and disable of add-on program of JP1/IM - Agent.

## Format

```
jpc_service {-on | -off} service-name  
                [-h logical-hostname]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In Linux: Superuser permissions

## Storage directory

In Windows:

*Agent-path\tools\*

In Linux:

*/opt/jplima/tools/*

## Arguments

**-on** *service-name*

Enable add-on program specified in *service-name*.

Logical host's service name is *jpc\_add-on-directory-name#\_logical-hostname*, but specify **-on** option is *jpc\_add-on-directory-name#*.

**-off** *service-name*

Disable add-on program specified in *service-name*.

Logical host's service name is *jpc\_add-on-directory-name#\_logical-hostname*, but specify **-off** option is *jpc\_add-on-directory-name#*.

**-h** *logical-hostname*

Specifies *logical-hostname* when operating on a cluster system.

**#**

For the value specified in the *add-on-directory-name*, see *Appendix A.4 (5) About add-on directory names* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## Notes

- If the string that you specify in the argument contains spaces or special characters, you must enclose them in " " and escape them.  
In addition, the following characters cannot be used:
  - " (double quotation mark)
  - ! (exclamation)

- % (percent)
- ^ (circumflex)
- OracleDB exporter cannot be enabled or disabled.

## Return values

|     |                                                                         |
|-----|-------------------------------------------------------------------------|
| 0   | Service Enable activated/deactivated successfully                       |
| 1   | The service is already Enable or disabled.                              |
| 10  | Invalid argument                                                        |
| 11  | You do not have Execution permissions.                                  |
| 12  | Service is running                                                      |
| 13  | Other commands are executing                                            |
| 251 | Service name is invalid                                                 |
| 252 | Mandatory-services (imagent, imagentproxy, imagentaction) are specified |
| 254 | Service definition file not found                                       |
| 255 | Failed to activate/deactivate serviced Enable                           |

## Log output

- Output destination
  - In Windows:  
*Agent-path*\logs\tools\
  - In Linux:  
/opt/jplima/logs/tools/

## Example

```
jpc_service -on jpc_prometheus
```

# jpc\_service\_autostart

---

## Function

This command setups the automatic startup and shutdown of JP1/IM - Agent.

The service of imagent, imagentproxy, imagentaction and the service of add-on program on which the respective service is add are covered.

For Windows, the service's startup type is setup as follows:

-on: Auto

-off: Manual

In a clustered environment, Logical host does not allow setup for auto-start and auto-stop because startup and shutdown are controlled by the cluster software.

## Format

```
jpc_service_autostart {-on | -off}
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In Linux: Superuser permissions

## Storage directory

In Windows:

*Agent-path*\tools\

In Linux:

/opt/jplima/tools/

## Arguments

-on

Enable the auto start of add-on program.

-off

Disable the auto start of add-on program.

## Notes

- If the string that you specify in the argument contains spaces or special characters, you must enclose them in " " and escape them. In addition, the following characters cannot be used:
  - " (double quotation mark)
  - ! (exclamation)
  - % (percent)

- ^ (circumflex)
- Auto start/stop cannot be set in OracleDB exporter.

## Return values

|     |                                                                                                 |
|-----|-------------------------------------------------------------------------------------------------|
| 0   | Successfully Enable or disable service-auto-start (all succeeded or already Enable or disabled) |
| 10  | Invalid argument                                                                                |
| 11  | You do not have Execution permissions.                                                          |
| 13  | Other commands are executing                                                                    |
| 255 | Failed to activate/deactivate Enable for service auto start                                     |

## Log output

- Output destination
  - In Windows:  
*Agent-path*\logs\tools\
  - In Linux:  
/opt/jplima/logs/tools/

## Example

```
jpc_service_autostart -on
```

# jpc\_service\_start

---

## Function

This command starts JP1/IM - Agent service.

## Format

```
jpc_service_start -s service-key
                  [-h logical-hostname]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In Linux: Superuser permissions

## Storage directory

In Windows:

*Agent-path*\tools\

In Linux:

/opt/jplima/tools/

## Arguments

-s *service-key*

Specify the service key.

If "all" is specified, all JP1/IM - Agent services are started.

-h *logical-hostname*

Specifies logical host name when operating on a cluster system.

## Notes

- If the string that you specify in the argument contains spaces or special characters, you must enclose them in " " and escape them. In addition, the following characters cannot be used:
  - " (double quotation mark)
  - ! (exclamation)
  - % (percent)
  - ^ (circumflex)
- OracleDB exporter cannot be started.

## Return values

|    |                                                                  |
|----|------------------------------------------------------------------|
| 0  | Service started successfully (all successful or already started) |
| 10 | Invalid argument                                                 |
| 11 | You do not have executing permissions.                           |

|     |                              |
|-----|------------------------------|
| 13  | Other commands are executing |
| 251 | Service key is invalid       |
| 253 | Service is not enabled       |
| 255 | Service failed to start      |

## Log output

- Output destination
  - In Windows:  
*Agent-path*\logs\tools\
  - In Linux:  
/opt/jplima/logs/tools/

## Example

```
jpc_service_start -s all
```

# jpc\_service\_stop

---

## Function

This command stops JP1/IM - Agent service.

## Format

```
jpc_service_stop -s service-key
                  [-f]
                  [-h logical-hostname]
```

## Execution permission

In Windows: Administrator permissions (if the Windows UAC feature is enabled, the command is executed from the administrator console)

In Linux: Superuser permissions

## Storage directory

In Windows:

*Agent-path*\tools\

In Linux:

/opt/jplima/tools/

## Arguments

-s *service-key*

Specify the service key.

If "all" is specified, all JP1/IM - Agent services are started.

-f

This option forcibly stops the service. Specifies when you want to stop forcibly working service process during cluster operation.

-h *logical-hostname*

Specifies logical host name when operating on a cluster system.

## Notes

- If the string that you specify in the argument contains spaces or special characters, you must enclose them in " " and escape them. In addition, the following characters cannot be used:
  - " (double quotation mark)
  - ! (exclamation)
  - % (percent)
  - ^ (circumflex)
- OracleDB exporter cannot be stopped.

## Return values

|     |                                                                  |
|-----|------------------------------------------------------------------|
| 0   | Service stopped successfully (all successful or already stopped) |
| 10  | Invalid argument                                                 |
| 11  | You do not have execution permissions.                           |
| 13  | Other commands are executing                                     |
| 251 | Service key is invalid                                           |
| 253 | Service is not enabled                                           |
| 255 | Service Failed to Stop                                           |

## Example

```
jpc_service_stop -s all
```

# jpc\_stop\_node\_exporter\_aix (AIX only)

## Function

This command stops Node exporter for AIX.

The log file of this command is output to the system log of OS.

## Format

```
jpc_stop_node_exporter_aix
    [-f]
    [-h logical-hostname]
```

## Execution permission

Superuser permissions

## Storage directory

It is stored in the directory where Node exporter for AIX archived file (node\_exporter\_aix\_VVRRSS.tar.Z) is extracted.

- When operating on a physical host

```
any-directory/node_exporter_aix/jplima/bin/
```

- When operating on a logical host

```
shared-directory/node_exporter_aix/jplima/bin/
```

## Arguments

- f**
- This option forcibly stops the service. Specifies that the service process being started is to be forcibly stopped during cluster operation.
- h logical-hostname**
- Specifies the logical host name when operating on a cluster system.
- If the logical hostname is 8 bytes or more, in (1) *Enabling registering services* or (3) *Registering the service changed* of 10.4.2 *Servicing Node exporter for AIX* in the *JP1/Integrated Management 3 - Manager Administration Guide*, specify any character string up to 7 characters specified in the logical host name as **-h** option.

## Notes

When operating on a physical host, if the execution path of the node\_exporter\_aix registered to the service is different from the jpc\_stop\_node\_exporter\_aix command, the jpc\_stop\_node\_exporter\_aix command terminates normally and the service is stopped, but the node\_exporter\_aix process remains running.

## Return values

|    |                                                              |
|----|--------------------------------------------------------------|
| 0  | Service stopped successfully (successful or already stopped) |
| 10 | Invalid argument                                             |

|     |                                        |
|-----|----------------------------------------|
| 11  | You do not have execution permissions. |
| 253 | Service is not enabled                 |
| 255 | Service Failed to Stop                 |

## Example

```
jpc_stop_node_exporter_aix
```

# jr3slget

---

## Function

The `jr3slget` command extracts the system log information of the SAP system.

## Format

```
jr3slget      [RFC-connection-information]
               [target-information]
               [-lasttime timestamp-file-name]
               [output-destination]
               [-cnf environment-parameters-file-name]
               [-help]
               [-v]
```

## Host that can execute the command

Integrated agent host

## Execution permissions

In Windows:

None

In Linux:

None

## Storage directory

### ■ Integrated agent host

In Windows:

- For a physical host:

*Folder-to-extract-the-archive-file<sup>#</sup>-for-SAP-system-monitoring-for-Windows* \sap\_windows\command\agtm\evtrap\

#

*Agent-path* \options\sap\_windows\_VVRRSS.zip

In Linux:

- For a physical host:

*Directory-to-extract-the-archive-file<sup>#</sup>-for-SAP-system-monitoring-for-Linux* /sap\_linux/command/agtm/evtrap/

#

/opt/jplima/options/sap\_linux\_VVRRSS.tar.gz

## Arguments

### *RFC-connection-information*

Specifies the information needed to establish RFC connection with the SAP system for command execution.

You can omit specification of this argument if you have specified the RFC connection information in the environment parameters file (CONNECT section). If the RFC connection information is specified in both the environment parameters file and the command, the command specification takes effect. For details about the environment parameters file, see [Environment parameters file for jr3slget command \(jr3slget.ini\)](#) in *Chapter 2. Definition Files*. The following describes the RFC information argument:

**-h** *application-server-host-name*

Specifies as 1-100 single-byte alphanumeric characters the name of the connection-target application server host. You must specify one of the following:

- Host name specified in the `hosts` file
- IP address
- SAP router address

You can verify the application server host name by transaction code SM51.

When you specify this option, you must also specify the `-s` option.

**-s** *system-number*

Specifies the system number for identification by the application server host specified with the `-h` option. You must specify a value in the range 0-99.

When you specify this option, you must also specify the `-h` option.

**-c** *client-name*

Specifies as 1-3 bytes the client name of the user that is to be used for connection. You must specify a value in the range 0-999.

When you specify this option, you must also specify the `-u` option together with the `-p` or `-p2` option.

**-u** *user-name*

Specifies as 1-12 single-byte alphanumeric characters the user name that is to be used for connection.

When you specify this option, you must also specify the `-c` option together with the `-p` or `-p2` option.

For details about the SAP users that can be specified, see [SAP users used for establishing connection](#).

**-p** *password*

Specifies the password for the user specified in the `-u` option. The permitted value is 1-8 single-byte characters.

This option and the `-p2` option are mutually exclusive.

When you specify this option, you must also specify the `-c` and `-u` options.

Specify this option when the SAP system is applying the conventional password rules.

For details about the characters permitted for the password, see [SAP users used for establishing connection](#).

**-p2** *extended-password*

Specifies the extended password for the user specified in the `-u` option. The permitted value is 1-40 single-byte characters. This value is case sensitive.

This option and the `-p` option are mutually exclusive.

When you specify this option, you must also specify the `-c` and `-u` options.

Specify this option when the SAP system is applying the extended password rules.

For details about the characters permitted for the extended password, see [SAP users used for establishing connection](#).

**-l** *language*

Specifies the language for the user specified with the `-u` option. You must specify a double-byte ISO ID or a single-byte language key used in the SAP system. For example:

- To specify Japanese: JA
- To specify a language other than Japanese: EN

If you omit this option, the user's language used in the connection-target system is assumed.

When you specify this option, you must also specify the `-c` option, the `-u` option, and the `-p` or `-p2` option.

#### `-codepage code-page`

Specifies the code page to be used when character encoding is converted in the Unicode version of the SAP system. The code page must be specified together with a language in the `-l` option.

Specify the combination of language and code page as shown below. If any other combination of language and code page is specified, an encoding error may occur in the information acquired from the SAP system.

**Table 1–59: Combination of language and code page specifications**

| Connection-target SAP system | Connection language | Language (-l) | Code page (-codepage)                                         |
|------------------------------|---------------------|---------------|---------------------------------------------------------------|
| Unicode version              | Japanese            | JA            | 8000                                                          |
|                              | English             | EN            | No need to specify. If you specify a code page, specify 1100. |
| Non-Unicode version          | Japanese            | JA            | No need to specify. If you specify a code page, specify 8000. |
|                              | English             | EN            | No need to specify. If you specify a code page, specify 1100. |

To set the code page to be used to convert character codes at the connection-target SAP system (Unicode version), you can also use the `SAP_CODEPAGE` environment variable provided by the SAP system. If the code page setting is specified in both the `SAP_CODEPAGE` environment variable and in this option, this option takes effect.

If this option is omitted, the connection-target system's default code page is assumed. When you specify this option, you must also specify the `-c` option, the `-u` option, and the `-p` or `-p2` option.

#### *target-information*

Specifies information that identifies the system log information that is to be extracted.

You can omit specification of this argument if you have specified the target information in the environment parameters file (TARGET section). If target information is specified in both the environment parameters file and the command, the command specification takes effect. For details about the environment parameters file, see [Environment parameters file for jr3slget command \(jr3slget.ini\)](#) in *Chapter 2. Definition Files*.

The following describes the target information argument:

#### `-server SAP-instance-name`

Specifies as 1-20 single-byte alphanumeric characters the name of the SAP instance that is collecting system log information. You can specify only one SAP instance name. To check the SAP instance name, use transaction code SM50 or SM66.

#### `-lasttime timestamp-file-name`

If only the system log information that was output after the previous command execution is to be extracted, this option specifies the name of the timestamp file used for managing the previous extraction time.

The permitted value is 1-255 single-byte characters.

If you specify a relative path, make sure that it is relative to the work directory for the command. If you have not specified a work directory for the command in the `WORKDIR` label of the `COMMAND` section in the environment parameters file, specify the path relative to the current directory.

If you omit this option, the system assumes the period from 00:00:00 to 23:59:59 on the command execution date.

If the specified timestamp file does not exist the first time the command is executed with this argument specified, a new timestamp file is created. System log information is not output during such a first-time execution.

#### *output-destination*

Specifies the output destination of the system log information. When you omit this argument, system log information separated by linefeed codes is output to the standard output.

There are two different file formats used by JP1/IM - Agent to output system log information as described below.

- **WRAP1**

This file is in wraparound format, which means that data is overwritten when the amount of system log Information reaches a specified value. Only one output file can be specified when using this format.

- **WRAP2**

In this file format, when the amount of system log Information reaches a specified value, data is deleted from the file and then new data is written from the beginning of the file. When the amount of data in the first file reaches a specified value, new data is written in the second file, starting at the top, after all existing data is deleted from the second file. When all of the files are full, new data is again written in the first file, starting at the top, after all existing data is deleted from the first file.

There can be two through nine output files when using this format. The default is 5 output files. The number of output files is specified in the **NUM** label in the **EXTRACTFILE** section in the environment parameters file.

If you want to change the format of output files, first stop any products monitoring the output files, and then delete the output files and their management files (if there is any).

The following describes the output destination argument:

#### *-x The-name-of-the-storage-file-in-WRAP1-format*

Specifies the relative or full path name of the **WRAP1**-format file to which system log information is to be output. The permitted value is 1 through 251 bytes of single-byte characters.

If you specify a relative path, make sure that it is relative to the work directory for the command. If you have not specified a work directory for the command in the **WORKDIR** label of the **COMMAND** section in the environment parameters file, specify the path relative to the current directory.

There is a header line of management information at the beginning of this file.

The default file size is 1024 kilobytes. To change the file size, use the **SIZE** label in the **EXTRACTFILE** section of the environment parameters file.

A management file having the name *output-file-name*.ofs is created in the same directory as for the output file. For example, if **SYSLOG** is specified as the output file name, a management file named **SYSLOG**.ofs is created in addition to the **SYSLOG** file. If you delete the output file, you must also delete this management file.

The **-x**, **-x2**, and **-xw** options are mutually exclusive.

#### *-xw The-prefix-for-the-storage-files-in-WRAP2-format*

Specifies the name of **WRAP2**-format file in which system log information is to be stored. The permitted value is 1 through 254 bytes of single-byte characters. For the actual file name, a one-byte number is added at the end of the specified file name.

A number in the range from 1 through **NUM** label value is assigned to the specified file name based on the value specified in the **NUM** label in the **EXTRACTFILE** section in the environment parameters file. For example, if **SYSLOG** is specified, storage files **SYSLOG1** through **SYSLOG5** are created by default.

If you specify a relative path, specify a path relative to the command's working directory. If no working directory is specified for commands in the **WORKDIR** label of the **COMMAND** section in the environment parameters file, specify a path relative to the current directory.

The default file size is 10,240 kilobytes. If you want to change the file size, specify a new size in the **SIZE** label in the **EXTRACTFILE** section in the environment parameters file.

The **-xw**, **-x**, and **-x2** options are mutually exclusive.

-x2

Specifies that system log information is to be output to the file that was specified in the X2PATH label in the EXTRACTFILE section in the environment parameters file.

The -x2, -x, and -xw options are mutually exclusive.

-cnf *environment-parameters-file-name*

Specifies the name of the environment parameters file that is to be referenced by the command. The permitted value is 1-255 bytes of single-byte characters.

If you specify a relative path, make sure that it is relative to the current directory for the command.

If you omit this argument, the system assumes jr3slget.ini, which is the default environment parameters file in the current directory. If there is no default environment parameters file, JP1/IM - Agent assumes the default settings for an environment parameters file.

For details about the environment parameters file and the default settings, see *Environment parameters file for jr3slget command (jr3slget.ini)* in *Chapter 2. Definition Files*.

-help

Specified that the usage of the jr3slget command is to be displayed at the standard output.

-v

Specifies that a message indicating the processing status of the jr3slget command is to be output to the standard output. If you omit this option, no message indicating the processing status of the command will be output.

## SAP users used for establishing connection

To collect system log information, the jr3slget command executes the external management interfaces defined in the SAP system using RFC (communication protocol of SAP AG). Therefore, you must provide in advance the users who are to be used by the jr3slget command for establishing connection in the SAP system. This subsection describes the user types, passwords, and authorizations for the SAP users who are created in the SAP system.

### User types

The following types of SAP users can be used by JP1/IM - Agent:

- Dialog
- System
- Communication
- Service

### Characters permitted for passwords

Define passwords for the SAP users. A password can consist of single-byte numeric characters (from 0 to 9), single-byte alphabetic characters (from a to z, A to Z), and the following single-byte symbols:

!, @, \$, %, &, /, (, ), =, ?, ', `\*, +, ~, #, -, \_, ., :, {, [, ], }, <, >, |

### Required authorizations

You must set the following authorizations (authorization objects) for the users:

- Authorizations required for a user to establish RFC connection with function modules (S\_RFC)
- Authorizations required in order to use external management interfaces (S\_XMI\_PROD)

For the value of each authorization, assign a value shown in the tables below or use the built-in configurations (S\_RFC\_ALL and S\_XMI\_ADMIN) that specify an asterisk (\*) for all items.

**Table 1–60: Authorizations required for a user to establish RFC connection with function modules (S\_RFC)**

| Authorization | Description                        | Value                 |
|---------------|------------------------------------|-----------------------|
| RFC_TYPE      | Type of RFC object to be protected | FUGR (function group) |
| RFC_NAME      | RFC name to be protected           | *                     |
| ACTVT         | Activity                           | 1 6 (execution)       |

**Table 1–61: Authorizations required in order to use external management interfaces (S\_XMI\_PROD)**

| Authorization | Description                                  | Value   |
|---------------|----------------------------------------------|---------|
| EXTCOMPANY    | Company name of the external management tool | HITACHI |
| EXTPRODUCT    | Program name of the external management tool | JP1     |
| INTERFACE     | Interface ID                                 | *       |

## Note

To use the remote monitoring function, you have to specify information (host name, instance name, etc.) regarding the SAP system to be monitored for the following settings: the RFC connection information or target information to be specified as a command argument, and the `CONNECT` section in the environment parameters file.

## Output format and contents

The command extracts the system log information (including parameter record rows) that can be verified by transaction code SM21 in the SAP system.

The following is the default output format for system log information, where `< >` enclose a field ID:

```
<TIME><INSTANCE><USER><PROGRAM><MSGNO><MSGTEXT>
```

If the value of a system log information item is shorter than the predefined field length, the remaining area is padded with single-byte spaces. The following table lists and explains the values that are output:

**Table 1–62: System log information that is output**

| Field ID   | Description                                       | Length (bytes) |
|------------|---------------------------------------------------|----------------|
| <TIME>     | Time the message was recorded ( <i>HH:MM:SS</i> ) | 8              |
| <INSTANCE> | Server that recorded the message                  | 20             |
| <USER>     | User who recorded the message                     | 12             |
| <PROGRAM>  | Program that recorded the message                 | 8              |
| <MSGNO>    | Message number                                    | 3              |
| <MSGTEXT>  | Message text                                      | 255            |

## Return value

|   |                    |
|---|--------------------|
| 0 | Normal termination |
|---|--------------------|

|              |                      |
|--------------|----------------------|
| 1 or greater | Abnormal termination |
|--------------|----------------------|

## Example

This example outputs the system log information for the o246bci\_SD5\_00 SAP instance. The RFC connection information has already been defined in the environment parameters file.

```
jr3slget -server o246bci_SD5_00
```

The output example from this command is as follows:

```
13:58:04o246bci_SD5_00 SAPSYS SAPMSSY8R49Communication error, CPIC return code 027,
SAP return code 456
13:58:04o246bci_SD5_00 SAPSYS SAPMSSY8R64> CPI-C function: CMINIT(SAP)
```

# jr3alget

---

## Function

The `jr3alget` command extracts the CCMS alert information of the SAP system.

## Format

```
jr3alget      [RFC-connection-information]
               [target-information]
               [-lasttime timestamp-file-name]
               [output-destination]
               [-cnf environment-parameters-file-name]
               [-help]
               [-v]
```

## Host that can execute the command

Integrated agent host

## Execution permissions

In Windows:

None

In Linux:

None

## Storage directory

### ■ Integrated agent host

In Windows:

- For a physical host:

*Folder-to-extract-the-archive-file<sup>#</sup>-for-SAP-system-monitoring-for-Windows* \sap\_windows\command\agtm\evtrap\  
#

*Agent-path* \options\sap\_windows\_VVRRSS.zip

In Linux:

- For a physical host:

*Directory-to-extract-the-archive-file<sup>#</sup>-for-SAP-system-monitoring-for-Linux* /sap\_linux/command/  
agtm/evtrap/  
#

/opt/jplima/options/sap\_linux\_VVRRSS.tar.gz

## Arguments

### *RFC-connection-information*

Specifies the information needed to establish RFC connection with the SAP system for command execution.

You can omit specification of this argument if you have specified the RFC connection information in the environment parameters file (CONNECT section). If the RFC connection information is specified in both the environment parameters file and the command, the command specification takes effect. For details about the environment parameters file, see [Environment parameters file for jr3alget command \(jr3alget.ini\)](#) in *Chapter 2. Definition Files*. The following describes the RFC information argument:

**-h** *application-server-host-name*

Specifies as 1-100 single-byte alphanumeric characters the name of the connection-target application server host. You must specify one of the following:

- Host name specified in the `hosts` file
- IP address
- SAP router address

You can verify the application server host name by transaction code SM51.

When you specify this option, you must also specify the `-s` option.

**-s** *system-number*

Specifies the system number for identification by the application server host specified with the `-h` option. You must specify a value in the range 0-99.

When you specify this option, you must also specify the `-h` option.

**-c** *client-name*

Specifies as 1-3 bytes the client name of the user that is to be used for connection. You must specify a value in the range 0-999.

When you specify this option, you must also specify the `-u` option together with the `-p` or `-p2` option.

**-u** *user-name*

Specifies as 1-12 single-byte alphanumeric characters the user name that is to be used for connection.

When you specify this option, you must also specify the `-c` option together with the `-p` or `-p2` option.

For details about the SAP users that can be specified, see [SAP users used for establishing connection](#).

**-p** *password*

Specifies the password for the user specified in the `-u` option. The permitted value is 1-8 single-byte characters.

This option and the `-p2` option are mutually exclusive.

When you specify this option, you must also specify the `-c` and `-u` options.

Specify this option when the SAP system is applying the conventional password rules.

For details about the characters permitted for the password, see [SAP users used for establishing connection](#).

**-p2** *extended-password*

Specifies the extended password for the user specified in the `-u` option. The permitted value is 1-40 single-byte characters. This value is case sensitive.

This option and the `-p` option are mutually exclusive.

When you specify this option, you must also specify the `-c` and `-u` options.

Specify this option when the SAP system is applying the extended password rules.

For details about the characters permitted for the extended password, see [SAP users used for establishing connection](#).

**-l** *language*

Specifies the language for the user specified with the `-u` option. You must specify a double-byte ISO ID or a single-byte language key used in the SAP system. For example:

- To specify Japanese: JA
- To specify a language other than Japanese: EN

If you omit this option, the user's language used in the connection-target system is assumed.

When you specify this option, you must also specify the `-c` option, the `-u` option, and the `-p` or `-p2` option.

#### `-codepage code-page`

Specifies the code page to be used when character encoding is converted in the Unicode version of the SAP system.

The code page must be specified together with a language in the `-l` option.

Specify the combination of language and code page as shown below. If any other combination of language and code page is specified, an encoding error may occur in the information acquired from the SAP system.

**Table 1–63: Combination of language and code page specifications**

| Connection-target SAP system | Connection language | Language (-l) | Code page (-codepage)                                         |
|------------------------------|---------------------|---------------|---------------------------------------------------------------|
| Unicode version              | Japanese            | JA            | 8000                                                          |
|                              | English             | EN            | No need to specify. If you specify a code page, specify 1100. |
| Non-Unicode version          | Japanese            | JA            | No need to specify. If you specify a code page, specify 8000. |
|                              | English             | EN            | No need to specify. If you specify a code page, specify 1100. |

To set the code page to be used to convert character codes at the connection-target SAP system (Unicode version), you can also use the `SAP_CODEPAGE` environment variable provided by the SAP system. If the code page setting is specified in both the `SAP_CODEPAGE` environment variable and in this option, this option takes effect.

If this option is omitted, the connection-target system's default code page is assumed. When you specify this option, you must also specify the `-c` option, the `-u` option, and the `-p` or `-p2` option.

#### *target-information*

Specifies information that identifies the CCMS alert information that is to be extracted.

You can omit specification of this argument if you have specified the target information in the environment parameters file (TARGET section). If target information is specified in both the environment parameters file and the command, the command specification takes effect. For details about the environment parameters file, see [Environment parameters file for jr3alget command \(jr3alget.ini\)](#) in *Chapter 2. Definition Files*.

The following describes the target information argument:

#### `-ms monitor-set-name`

Specifies as 1-60 single-byte alphanumeric characters the monitor set name. The monitor set name is displayed as CCMS monitor set on the Alert Monitor (transaction code RZ20) of the SAP system.

When you specify this option, you must also specify the `-mn` option.

#### `-mn monitor-name`

Specifies as 1-60 single-byte alphanumeric characters the monitor name defined in the monitor set. The monitor name is displayed in the tree of the CCMS monitor set on the Alert Monitor (transaction code RZ20) of the SAP system.

When you specify this option, you must also specify the `-ms` option.

#### `-lasttime timestamp-file-name`

If only the CCMS alert information that was output after the previous command execution is to be extracted, this option specifies the name of the timestamp file used for managing the previous extraction time.

The permitted value is 1-255 single-byte characters.

If you specify a relative path, make sure that it is relative to the work directory for the command. If you have not specified a work directory for the command in the `WORKDIR` label of the `COMMAND` section in the environment parameters file, specify the path relative to the current directory.

If you omit this option, the system assumes the period from 00:00:00 to 23:59:59 on the command execution date.

If the specified timestamp file does not exist the first time the command is executed with this argument specified, a new timestamp file is created. CCMS alert information is not output during such a first-time execution.

#### *output-destination*

Specifies the output destination of the CCMS alert information. When you omit this argument, CCMS alert information separated by linefeed codes is output to the standard output.

There are two different file formats used by JP1/IM - Agent to output CCMS Alert Information as described below.

- `WRAP1`

This file is in wraparound format, which means that data is overwritten when the amount of CCMS Alert Information reaches a specified value. There can be only one output file when using this format.

- `WRAP2`

In this file format, when the amount of CCMS Alert Information reaches a specified value, all data is deleted from the file and then new data is written from the beginning of the file. When the amount of data in the first file reaches a specified value, new data is written in the second file, starting at the top, after all existing data is deleted from the second file. When all of the files are full, new data is again written in the first file, starting at the top, after all existing data is deleted from the first file.

There can be two through nine output files when using this format. The default is 5 output files. The number of output files is specified in the `NUM` label in the `EXTRACTFILE` section in the environment parameters file.

If you want to change the format of output files, first stop any products monitoring the output files, and then delete the output files and their management files (if there is any).

The following describes the output destination argument:

#### *-x The-name-of-the-storage-file-in-WRAP1-format*

Specifies the relative or full path name of the `WRAP1`-format file in which CCMS Alert Information is to be stored. The permitted value is 1 through 251 bytes of single-byte characters.

If you specify a relative path, make sure that it is relative to the work directory for the command. If you have not specified a work directory for the command in the `WORKDIR` label of the `COMMAND` section in the environment parameters file, specify the path relative to the current directory.

There is a header line of management information at the beginning of this file.

The default file size is 1,024 kilobytes. To change the file size, use the `SIZE` label in the `EXTRACTFILE` section of the environment parameters file.

A management file having the name *storage-file-name*.`ofs` is created in the same directory as for the storage file. For example, if `ALERT` is specified as the storage file name, a management file named `ALERT.ofs` is created in addition to the `ALERT` file. If you delete the storage file, you must also delete this management file.

The `-x`, `-x2`, and `-xw` options are mutually exclusive.

#### *-xw The-prefix-for-the-storage-files-in-WRAP2-format*

Specifies the name of `WRAP2`-format file in which CCMS Alert Information is to be stored. The permitted value is 1 through 254 bytes of single-byte characters. For the actual file names, a one-byte number is added at the end of the specified file name.

A number in the range from 1 through the `NUM` label value is assigned to the specified file name based on the value specified in the `NUM` label in the `EXTRACTFILE` section in the environment parameters file. For example, if `ALERT` is specified, storage files `ALERT1` through `ALERT5` are created by default.

If you specify a relative path, specify a path relative to the command's working directory. If no working directory is specified for commands in the `WORKDIR` label of the `COMMAND` section in the environment parameters file, specify a path relative to the current directory.

The default file size is 10,240 kilobytes. If you want to change the file size, specify a new size in the `SIZE` label in the `EXTRACTFILE` section in the environment parameters file.

The `-xw`, `-x`, and `-x2` options are mutually exclusive.

`-x2`

Specifies that CCMS Alert Information is to be output to the file that was specified in the `X2PATH` label in the `EXTRACTFILE` section in the environment parameters file.

The `-x2`, `-x`, and `-xw` options are mutually exclusive.

`-cnf environment-parameters-file-name`

Specifies the name of the environment parameters file that is to be referenced by the command. The permitted value is 1-255 bytes of single-byte characters.

If you specify a relative path, make sure that it is relative to the current directory for the command.

If you omit this argument, the system assumes `jr3alget.ini`, which is the default environment parameters file in the current directory. If there is no default environment parameters file, JP1/IM - Agent assumes the default settings for an environment parameters file.

For details about the environment parameters file and the default settings, see [Environment parameters file for jr3alget command \(jr3alget.ini\)](#) in *Chapter 2. Definition Files*.

`-help`

Specifies that the usage of the `jr3alget` command is to be displayed at the standard output.

`-v`

Specifies that a message indicating the processing status of the `jr3alget` command is to be output to the standard output. If you omit this option, no message indicating the processing status of the command will be output.

## SAP users used for establishing connection

To collect CCMS alert information, the `jr3alget` command executes the external management interfaces defined in the SAP system using RFC (communication protocol of SAP AG). Therefore, you must provide in advance the users who are to be used by the `jr3alget` command for establishing connection in the SAP system. This subsection describes the user types, passwords, and authorizations for the SAP users who are created in the SAP system.

### User types

The following types of SAP users can be used by JP1/IM - Agent:

- Dialog
- System
- Communication
- Service

### Characters permitted for passwords

Define passwords for the SAP users. A password can consist of single-byte numeric characters (from 0 to 9), single-byte alphabetic characters (from a to z, A to Z), and the following single-byte symbols:

!, @, \$, %, &, /, (, ), =, ?, ', `\*, +, ~, #, -, \_, ., :, {, [, ], }, <, >, |

## Required authorizations

You must set the following authorizations (authorization objects) for the users:

- Authorizations required for a user to establish RFC connection with function modules (S\_RFC)
- Authorizations required in order to use external management interfaces (S\_XMI\_PROD)

For the value of each authorization, assign a value shown in the tables below or use the built-in configurations (S\_RFC\_ALL and S\_XMI\_ADMIN) that specify an asterisk (\*) for all items.

**Table 1–64: Authorizations required for a user to establish RFC connection with function modules (S\_RFC)**

| Authorization | Description                        | Value                 |
|---------------|------------------------------------|-----------------------|
| RFC_TYPE      | Type of RFC object to be protected | FUGR (function group) |
| RFC_NAME      | RFC name to be protected           | *                     |
| ACTVT         | Activity                           | 1 6 (execution)       |

**Table 1–65: Authorizations required in order to use external management interfaces (S\_XMI\_PROD)**

| Authorization | Description                                  | Value   |
|---------------|----------------------------------------------|---------|
| EXTCOMPANY    | Company name of the external management tool | HITACHI |
| EXTPRODUCT    | Program name of the external management tool | JP1     |
| INTERFACE     | Interface ID                                 | *       |

## Notes

- Because the CCMS alert information is treated as an SAP system resource and can be referenced from any application server, the connection target can be any application server. Make sure that only one command is executed per SAP system.
- To use the remote monitoring function, you have to specify information (host name, instance name, etc.) regarding the SAP system to be monitored for the following settings: the RFC connection information or target information to be specified as a command argument, and the CONNECT section in the environment parameters file.

## Output format and contents

The following is the default output format for CCMS alert information, where < > enclose a field ID:

<ALERTDATE><ALERTTIME><MTSYSID><MTMCNAME><OBJECTNAME><FIELDNAME><VALUE><SEVERITY><MSG>

If the value of a CCMS alert information item is shorter than the predefined field length, the remaining area is padded with single-byte spaces. The following table lists and explains the values that are output:

**Table 1–66: CCMS alert information that is output**

| Field ID   | Description                    | Source                      | Length (bytes) |
|------------|--------------------------------|-----------------------------|----------------|
| <ALSYSID>  | Name of the SAP system         | Alert ID (AID)<br>(BAPIAID) | 8              |
| <MSEGNAME> | Name of the monitoring segment |                             | 40             |

| Field ID     | Description                                                                                                                                                                                                                                                                                      | Source                                                     | Length (bytes) |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|----------------|
| <ALUNIQNUM>  | Unique ID used by AID                                                                                                                                                                                                                                                                            | ID of the MTE associated with the alert (TID)<br>(BAPITID) | 10             |
| <ALERTDATE>  | Date the alert occurred (YYYYMMDD)                                                                                                                                                                                                                                                               |                                                            | 8              |

| Field ID   | Description                                | Source | Length (bytes) |
|------------|--------------------------------------------|--------|----------------|
| <MSGARG3>  | Character string for message insert word 3 |        | 128            |
| <ARGTYPE3> | Type of message insert word 3              |        | 1              |
| <MSGARG4>  | Character string for message insert word 4 |        | 128            |
| <ARGTYPE4> | Type of message insert word 4              |        | 1              |
| <MSGTEXT>  | Message text                               |        | 128            |
| <MSG>      | Translated message                         |        | 255            |

## Return value

|              |                      |
|--------------|----------------------|
| 0            | Normal termination   |
| 1 or greater | Abnormal termination |

## Example

This example outputs CCMS alert information using SAP CCMS Monitor Templates as the monitor set name and Entire System as the monitor name. The RFC connection information has already been defined in the environment parameters file.

```
jr3alget -ms "SAP CCMS Monitor Templates" -mn "Entire System"
```

The output example from this command is as follows:

```
20030321171911SD5  o246bci_SD5_00  Background  AbortedJobs Job
DBA:CHECKOPT_____@021500/6007 (ID number 02153101)
terminated20030321171911SD5  o246bci_SD5_00  GenericKey  SpaceUsed  95 % > 90 %
15 min. avg. value over threshold value
```

# promtool

---

## Function

This command checks the format of Prometheus server definition files and tests alert rules.

## Format

```
promtool check config Prometheus-configuration-file-name
check rules alert-configuration-file-name
test rules test-file-name ...
```

## Execution permission

None

## Storage directory

In Windows:

*Agent-path*\tools\

In Linux:

/opt/jplima/tools/

## Arguments

check config *Prometheus-configuration-file-name*

Check the format of the Prometheus configuration file for errors.

For details about the Prometheus configuration file, see [Prometheus configuration file \(jpc\\_prometheus\\_server.yml\)](#).

check rules *alert-configuration-file-name*

Check for errors in the format of the alert configuration file.

For details about the alert configuration file, see [Alert configuration file \(jpc\\_alerting\\_rules.yml\)](#).

test rules *test-file-name* ...

Run a test of the alert rule that you wrote in the test file. You can specify up to 10 test files.

## Return values

|              |                                                    |
|--------------|----------------------------------------------------|
| 0            | Format is correct, and alert rule test successful. |
| other than 0 | Format is incorrect, and alert rule test failure.  |

## Alert rule test file contents

### Format

Write in YAML format.

### File

*Any-name*.yml

## Description

| Item name                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Default value |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| rule_files:<br>[ - <file_name> ]                   | Specify a list of rule files to consider for testing.<br>The file name can be specified as a wildcard.                                                                                                                                                                                                                                                                                                                                                                         | --            |
| [ evaluation_interval: <duration>   default = 1m ] | Specify the evaluation interval for the alert rule.                                                                                                                                                                                                                                                                                                                                                                                                                            | 1m            |
| group_eval_order:<br>[ - <group_name> ]            | You can specify the order of group names.<br>The order of the group names is the order in which the rule groups are evaluated (specific evaluation times). The order specified is guaranteed only for the group name described.<br>You don't have to describe every group.<br>You can specify the evaluation order of the rule file described in rule_files:, as shown in the following example.<br><Description example><br>group_eval_order:<br>- test02.yml<br>- test01.yml | --            |
| tests:<br>[ - <test_group> ]                       | Enumerate all tests.                                                                                                                                                                                                                                                                                                                                                                                                                                                           | --            |

## Sample alert configuration file and alert rule test file

### - Examples of "up" metrics

- Example of description of alert configuration file

```
groups:
- name: alerts
  rules:
    - alert: InstanceDown
      expr: up == 0
      for: 5m
      labels:
        severity: page
      annotations:
```

```
summary: "Instance {{ $labels.instance }} down"
description: "{{ $labels.instance }} of job {{ $labels.job }} has
been down for more than 5 minutes."
```

- Example of description of alert rule test file

```
rule_files:
  - jpc_alerting_rules.yml

evaluation_interval: 1m

tests:
  # Test
  - interval: 1m
    # Series data.
    input_series:
      - series: 'up{job="prometheus", instance="localhost:9090"}'
        values: '0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0' # success

    # Unit test for alerting rules.
    alert_rule_test:
      # Unit test 1.
      - eval_time: 5m
        alertname: InstanceDown
        # alertname: AnotherInstanceDown
        exp_alerts:
          # Alert 1.
          - exp_labels:
              severity: page
              instance: localhost:9090
              job: prometheus
            exp_annotations:
              summary: "Instance localhost:9090 down"
              description: "localhost:9090 of job prometheus has b
een down for more than 5 minutes."
```

## - Examples of CPU

- Example of description of alert configuration file

```
groups:
  - name: alerts
    rules:
      - alert: cpu_alert_rule
        expr: sum(rate(windows_cpu_time_total{mode!="idle"}[1m])) < 50
        for: 2m
        labels:
          severity: page
        annotations:
          summary: "CPU alert rule summary"
          description: "CPU alert rule description"
```

- Example of description of alert rule test file

```
rule_files:
  - jpc_alerting_rules.yml

evaluation_interval: 1m
```

```

tests:
  # Test
  - interval: 1m
    # Series data.
    input_series:
      - series: 'windows_cpu_time_total'
        #values: '0+3000x10' # fail
        values: '0+2800x10' # success

    # Unit test for alerting rules.
    alert_rule_test:
      # Unit test 1.
      - eval_time: 7m
        alertname: cpu_alert_rule
        exp_alerts:
          # Alert 1.
          - exp_labels:
              severity: page
            exp_annotations:
              summary: "CPU alert rule summary"
              description: "CPU alert rule description"

```

## - Examples of memory (#1)

- Example of description of alert configuration file

```

groups:
  - name: alerts
    rules:
      - alert: memory_alert_rule
        expr: windows_memory_available_bytes < 1073741824
        for: 3m
        labels:
          severity: page
        annotations:
          summary: "Memory alert rule summary"
          description: "Memory alert rule description"

```

- Example of description of alert rule test file

```

rule_files:
  - jpc_alerting_rules.yml

evaluation_interval: 1m

tests:
  # Test
  - interval: 1m
    # Series data.
    input_series:
      - series: 'windows_memory_available_bytes'
        values: '1073741822 1073741826 1073741823 1073741823 107374182
3 1073741823 1073741828 1073741822' # success
        #values: '1073741822 1073741822 1073741826 1073741823 10737418
23 1073741823 1073741828 1073741822' # fail

    # Unit test for alerting rules.

```

```

alert_rule_test:
  # Unit test 1.
  - eval_time: 5m
    alertname: memory_alert_rule
    exp_alerts:
      # Alert 1.
      - exp_labels:
          severity: page
        exp_annotations:
          summary: "Memory alert rule summary"
          description: "Memory alert rule description"

```

## - Examples of memory (#2)

- Example of description of alert configuration file

```

groups:
  - name: alerts
    rules:
      - alert: memory_alert_rule
        expr: windows_memory_available_bytes < 1073741824
        for: 3m
        labels:
          severity: page
        annotations:
          summary: "Memory alert rule summary"
          description: "Memory alert rule description"

```

- Example of description of alert rule test file

```

rule_files:
  - jpc_alerting_rules.yml

evaluation_interval: 1m

tests:
  # Test
  - interval: 1m
    # Series data.
    input_series:
      - series: 'windows_memory_available_bytes'
        values: '1073741822 1073741826 1073741823 1073741823 107374182
3 1073741823 1073741828 1073741822' # success
        #values: '1073741822 1073741822 1073741826 1073741823 10737418
23 1073741823 1073741828 1073741822' # fail

    # Unit test for alerting rules.
    alert_rule_test:
      # Unit test 1.
      - eval_time: 5m
        alertname: memory_alert_rule
        exp_alerts:
          # Alert 1.
          - exp_labels:
              severity: page
            exp_annotations:
              summary: "Memory alert rule summary"
              description: "Memory alert rule description"

```

## - Examples of interrupt

- Example of description of alert configuration file

```
groups:
- name: alerts
  rules:
    - alert: alerts_rules_increase
      expr: increase(window_cpu_interrupts_total{core="0,0"}[3m]) > 100
      for: 0m
      labels:
        severity: critical
      annotations:
        summary: "Alert test case of increase."
        description: "Use increase function in unit test."

    - alert: alerts_rules_increase_all
      expr: sum(increase(window_cpu_interrupts_total[5m])) > 240
      for: 0m
      labels:
        severity: critical
      annotations:
        summary: "Alert test case of increase."
        description: "Use increase function in unit test."
```

- Example of description of alert rule test file

```
rule_files:
- jpc_alerting_rules.yml

evaluation_interval: 1m

tests:
# Test
- interval: 1m
# Series data.
input_series:
- series: 'window_cpu_interrupts_total{core="0,0"}'
  #values: '0 10 20 30 110 120 130 140 150 160 170' #fail
  values: '0+10x3 111+10x6' #success
- series: 'window_cpu_interrupts_total{core="0,1"}'
  values: '0+10x3 98+13x6'

# Unit test for alerting rules.
alert_rule_test:
# Unit test 1.
- eval_time: 4m
  alertname: alerts_rules_increase
  exp_alerts:
    # Alert 1.
    - exp_labels:
        core: "0,0"
        severity: critical
      exp_annotations:
        summary: "Alert test case of increase."
        description: "Use increase function in unit test."
    - eval_time: 8m
      alertname: alerts_rules_increase_all
```

```
exp_alerts:
  # Alert 1.
  - exp_labels:
      severity: critical
    exp_annotations:
      summary: "Alert test case of increase."
      description: "Use increase function in unit test."
```

## Examples

- Example of performing a format check on a Prometheus configuration file (if the format is correct)

```
# ./promtool check config jpc_prometheus_server.yml
Checking jpc_prometheus_server.yml
  SUCCESS: 1 rule files found

Checking jpc_alerting_rules.yml
  SUCCESS: 1 rules found
```

- Example of performing a format check on a Prometheus configuration file (if the format is incorrect)

```
# ./promtool check config jpc_prometheus_server.yml
Checking jpc_prometheus_server.yml
  FAILED: parsing YAML file jpc_prometheus_server.yml: yaml: line 42: did
not find expected key
```

- Example of performing a format check of the alert configuration file (if the format is correct)

```
# ./promtool check rules jpc_alerting_rules.yml
Checking jpc_alerting_rules.yml
  SUCCESS: 1 rules found
```

- Example of performing a format check of the alert configuration file (if the format is incorrect)

```
# ./promtool check rules jpc_alerting_rules.yml
Checking jpc_alerting_rules.yml
  FAILED:
jpc_alerting_rules.yml: yaml: unmarshal errors:
  line 10: field aannotations not found in type rulefmt.RuleNode
```

- Example of running an alert rule test (if the test is successful)

```
# ./promtool test rules alerts_rules_unit_test.yml
Unit Testing: alerts_rules_unit_test.yml
  SUCCESS
```

- Example of running an alert rule test (if the test fails (Part 1))

```
# ./promtool test rules alerts_rules_unit_test.yml
Unit Testing: alerts_rules_unit_test.yml
  FAILED:
  alertname:InstanceDown, time:10m,
    exp:"[Labels:{alertname=\"InstanceDown\", instance=\"localhost:9090\", job=\"prometheus\", severity=\"page\"} Annotations:{description=\"localhost:9090 of job prometheus has been down for more than 5 minutes.\", summary=\"Instance localhost:9090 down\"}]",
    got:"["
```

If the test file is invalid, an alert that is expected to occur in `exp` and an alert that actually occurs in `got` are output. In the case of the above execution example, it indicates that no alert was actually notified (output result of `got`) for the expectation that one alert is output (output result of `exp`).

- Example of running an alert rule test (if the test fails (Part 2))

```
# ./promtool test rules test_rule_file.yml
Unit Testing:  test_rule_file.yml
FAILED:
  alertname:InstanceDown, time:5m,
    exp:"[Labels:{alertname=\"InstanceDown\", instance=\"localhost:9090\", job=\"prometheus\", severity=\"warn\"} Annotations:{description=\"localhost:9090 of job prometheus has been down for more than 5 minutes.\", summary=\"Instance localhost:9090 down\"}]",
    got:"[Labels:{alertname=\"InstanceDown\", instance=\"localhost:9090\", job=\"prometheus\", severity=\"page\"} Annotations:{description=\"localhost:9090 of job prometheus has been down for more than 5 minutes.\", summary=\"Instance localhost:9090 down\"}]"
```

If the test file is invalid, an alert that is expected to occur in `exp` and an alert that actually occurs in `got` are output. In the above execution example, it is assumed that the value of `severity` is `warn` (output result of `exp`), but the value of `severity` is actually `page` (output result of `got`).

# SpmSetSvcCon (Windows only)

---

## Function

This command sets or cancels dependencies between the JP1/IM-Manager service and the JP1/Base Event service. If only JP1/IM - Manager needs to be deleted from a logical host, this command can also delete only the JP1/IM-Manager service on the logical host.

## Format

```
SpmSetSvcCon {-setdepend {yes|no} | -d -h logical-host-name}
```

## Execution permission

Administrator permissions (If the Windows UAC feature is enabled, the command is executed from the administrator console)

## Storage directory

*Console-path*\bin\

## Arguments

`-setdepend {yes|no}`

Sets the dependencies for a registered service.

- `yes`: Sets the dependencies between the JP1/IM-Manager service and the JP1/Base Event service.
- `no`: Cancels the dependencies between the JP1/IM-Manager service and the JP1/Base Event service.

`-d -h logical-host-name`

Specify this option to delete only JP1/IM - Manager from a logical host. For details about the procedure for deleting only JP1/IM - Manager from a logical host, see *7.7.1(4) Deleting only JP1/IM - Manager and IM databases on a logical host* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

## Return values

|     |                                              |
|-----|----------------------------------------------|
| 0   | Normal termination                           |
| 1   | Argument error                               |
| 2   | Execution permission error                   |
| 3   | The JP1/IM-Manager service is not registered |
| 255 | Other error                                  |

# 2

## Definition Files

This chapter describes the format and syntax of JP1/IM definition files.

## 2.1 List of definition files

The following table lists the JP1/Integrated Management definition files.

Table 2–1: List of definition files

| Product name     |                                        | Definition file name                                                                                           | Description                                                                                                                                                                               |
|------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JP1/Base         |                                        | Configuration definition file                                                                                  | Defines the system hierarchy that is to be managed by JP1/IM. For details about the configuration definition file ( <code>jbs_route.conf</code> ), see the <i>JP1/Base User's Guide</i> . |
|                  |                                        | Environment variable file <sup>#3</sup>                                                                        | Defines environment variables to be used when commands are executed at managed hosts in JP1/IM. For details about the environment variable file, see the <i>JP1/Base User's Guide</i> .   |
|                  |                                        | Host group definition file                                                                                     | Defines a group of managed hosts in JP1/IM. For details about the host group definition file, see the <i>JP1/Base User's Guide</i> .                                                      |
| JP1/IM - Manager | JP1/IM - Manager                       | Common definition settings file (changing the attribute of JP1 events)                                         | Changes the attribute of JP1 events.                                                                                                                                                      |
|                  |                                        | Operation log definition file ( <code>imm_operationlog.conf</code> )                                           | Defines whether to output operation log data, the output destination, log file size, and number of files.                                                                                 |
|                  | Intelligent Integrated Management Base | Intelligent Integrated Management Base definition file ( <code>imdd.properties</code> )                        | Defines system settings for the Intelligent Integrated Management Base.                                                                                                                   |
|                  |                                        | System node definition file ( <code>imdd_systemnode.conf</code> ) <sup>#3</sup>                                | Contains settings to define the hierarchical structure of the system to represent the structure in a sunburst or tree chart, and settings to group collected data into defined hosts.     |
|                  |                                        | Category name definition file for IM management nodes ( <code>imdd_category_name.conf</code> ) <sup>#3</sup>   | Defines IM management node category names for management groups to be displayed in a sunburst or tree chart.                                                                              |
|                  |                                        | Target host definition file for configuration collection ( <code>imdd_target_host.conf</code> ) <sup>#3</sup>  | Defines the hosts from which to collect information regarding monitoring objects of each linked product.                                                                                  |
|                  |                                        | Host name definition file ( <code>imdd_host_name.conf</code> ) <sup>#3</sup>                                   | Defines mapping between aliases and real host names.                                                                                                                                      |
|                  |                                        | IM management node link definition file ( <code>imdd_nodeLink_def.conf</code> ) <sup>#3</sup>                  | Defines relationships between IM management nodes.                                                                                                                                        |
|                  |                                        | Suggestion definition file ( <code>imdd_suggestion.conf</code> ) <sup>#3</sup>                                 | Defines criteria for suggesting response actions and what the actions do, which are used by the suggestion function.                                                                      |
|                  |                                        | Suggestion definition file (user-created) ( <code>imdd_suggestion_any-file-name.conf</code> ) <sup>#3,#4</sup> |                                                                                                                                                                                           |
|                  |                                        | Single sign-on mapping definition file ( <code>imdd_sso_mapping.properties</code> ) <sup>#3</sup>              | Defines the mapping between the name of the JP1 user used in the Intelligent Integrated Management Base and the name of the user registered in the OpenID provider.                       |

| Product name |                 | Definition file name                                                                                 | Description                                                                                                                                                                |
|--------------|-----------------|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              |                 | Auto response action definition file<br>(autoactconf.json) <sup>#3</sup>                             | A file that restores execution conditions in Automatic Response Action and Automatic Response Action definition, which is executed contents are recorded.                  |
|              |                 | Response action state monitoring definition file (responseactionnotice.conf)                         | A file that defines setup for monitoring execute status for automated Response Action.                                                                                     |
|              |                 | User-created definition file list definition file (imdd_user_deffile_list.json) <sup>#3</sup>        | A file that defines a user-created file that can be updated or delete with the functions provided by JP1/IM - Manager.                                                     |
|              |                 | Definition file properties file (imdd_file_properties.json)                                          | This File defines file name, file path, and the operation for importing the definition file when acquiring or updating the definition file.                                |
|              | Central Console | Event-source-host mapping definition file (user_hostmap.conf) <sup>#3</sup>                          | Defines mapping on the event source host.                                                                                                                                  |
|              |                 | Automated action environment definition file (action.conf.update)                                    | Defines an execution environment for automated actions.                                                                                                                    |
|              |                 | Automated action definition file (actdef.conf)                                                       | Defines conditions for executing an automated action and the command to be executed as the action.                                                                         |
|              |                 | Automated action definition file (actdef.conf) (for conversion)                                      | Defines (for conversion) conditions for executing an automated action and the command to be executed as the action.                                                        |
|              |                 | Automatic action notification definition file (actnotice.conf)                                       | Defines the automated action status notification function.                                                                                                                 |
|              |                 | Extended startup process definition file (jp1co_service.conf)                                        | Defines process information for the functions that constitute JP1/IM - Manager.                                                                                            |
|              |                 | IM parameter definition file (jp1co_param_v7.conf)                                                   | Defines whether a JP1 event is to be issued when JP1/IM - Manager processes fail or when JP1/IM - Manager processes are recovered automatically from abnormal termination. |
|              |                 | System profile (.system)                                                                             | Defines environment information for the basic operation of the event console.                                                                                              |
|              |                 | User profile (defaultUser   profile_user-name)                                                       | Defines environment information for how the Event Console window is displayed.                                                                                             |
|              |                 | Communication environment definition file (console.conf.update)                                      | Defines communication processing (timeout period) among JP1/IM - Manager, the viewer, and the jcochstat command.                                                           |
|              |                 | Health check definition file (jcohc.conf) <sup>#3</sup>                                              | Defines whether the health check function is to be enabled.                                                                                                                |
|              |                 | Event guide information file (jco_guide.txt) <sup>#3,#4</sup>                                        | Defines event guide information for JP1 events that occur in the system and create problems.                                                                               |
|              |                 | Event guide information sample file (sample_jco_guide_ja.txt, sample_jco_guide_en.txt) <sup>#3</sup> | Sample files that defines event guide information for JP1 events that occur in the system and create problems.                                                             |
|              |                 | Status event definition file (processupdate.conf)                                                    | Defines whether a JP1 event is to be issued when the action status changes.                                                                                                |

| Product name |  | Definition file name                                                                                          | Description                                                                                                                                                                 |
|--------------|--|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              |  | Correlation event generation system profile (egs_system.conf) <sup>#3</sup>                                   | Defines the start and stop operations for the Event Generation Service.                                                                                                     |
|              |  | Correlation event generation definition file <sup>#3,#4</sup>                                                 | Defines the JP1 event conditions that result in generation of correlation events and the correlation events that are generated when the JP1 event conditions are satisfied. |
|              |  | Correlation event generation environment definition file <sup>#3,#4</sup>                                     | Defines the size and number of correlation event generation history files.                                                                                                  |
|              |  | Definition file for manually registering incidents (incident.conf)                                            | A definition file for linkage with JP1/Service Support. The file defines JP1/Service Support for linkage with JP1/IM - View.                                                |
|              |  | Configuration file for incident inheritance information (incident_info.conf)                                  | A configuration file for linkage with JP1/Service Support. The file defines JP1 events' attributes and character strings to be inherited by incidents.                      |
|              |  | Severity changing definition file (jcochsev.conf) <sup>#3</sup>                                               | Defines conditions for changing the severity of JP1 events and the new severity level.                                                                                      |
|              |  | Command button definition file (cmdbtn.conf) <sup>#3</sup>                                                    | Defines command buttons to be displayed in the Execute Command window.                                                                                                      |
|              |  | File that defines which items are displayed for event conditions (attr_list.conf)                             | Specifies the conversion rules for the automated action and command execution event inheritance function.                                                                   |
|              |  | Configuration file for converting information (event_info_replace.conf)                                       | Specifies the conversion rules for the automated action event inheriting function.                                                                                          |
|              |  | Item file                                                                                                     | Specifies the JP1 event attributes that are to be output during output of event reports.                                                                                    |
|              |  | Environment definition file for event report output (evtreport.conf)                                          | Defines the execution environment of the event report output function.                                                                                                      |
|              |  | Filter file                                                                                                   | Defines filter conditions to be applied during output of event reports.                                                                                                     |
|              |  | System color definition file (systemColor.conf) <sup>#3</sup>                                                 | Defines the color settings used for an event list.                                                                                                                          |
|              |  | Definition file for extended event attributes <sup>#3,#4</sup>                                                | Defines extended attributes of JP1 events.                                                                                                                                  |
|              |  | Definition file for extended event attributes (extended file) <sup>#3,#4</sup>                                | Defines the settings for displaying program-specific extended attributes of JP1 events as item names on the screen and in the output of event reports.                      |
|              |  | Definition file for object types                                                                              | Defines the object types of the extended attributes of JP1 events.                                                                                                          |
|              |  | Common-exclusion-conditions extended definition file <sup>#3,#4</sup>                                         | Defines the event conditions or the applicable period of the extended-mode common exclusion-conditions.                                                                     |
|              |  | Common-exclusion-conditions display item definition file (common_exclude_filter_attr_list.conf) <sup>#3</sup> | Specifies the items to be displayed in the <b>Attribute name</b> display area in the Common Exclusion-Conditions Settings (Extended) window.                                |

| Product name |               | Definition file name                                                                                           | Description                                                                                                                                           |
|--------------|---------------|----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
|              |               | Common-exclusion-conditions auto-input definition file<br>(common_exclude_filter_auto_list.conf) <sup>#3</sup> | Defines JP1 event attributes that are set automatically when the Common Exclusion-Conditions Settings (Extended) window opens.                        |
|              |               | Display item definition file for the repeated event condition<br>(event_storm_attr_list.conf) <sup>#3</sup>    | Specifies the items to be displayed in the <b>Attribute name</b> display area in the Repeated Event Condition Settings window.                        |
|              |               | Auto-input definition file for the repeated event condition<br>(event_storm_auto_list.conf) <sup>#3</sup>      | Defines the attribute of a JP1 event that is set automatically when the Repeated Event Condition Settings window opens.                               |
|              |               | Display item definition file for the severity change definition (chsev_attr_list.conf) <sup>#3</sup>           | A definition file that specifies the items to display in the <b>Attribute name</b> display area of the Severity Change Definition Settings window.    |
|              |               | Auto-input definition file for the severity change definition (chsev_auto_list.conf) <sup>#3</sup>             | Defines the JP1 event attribute that is set automatically when the Severity Change Definition Settings window opens.                                  |
|              |               | Definition file for opening monitor windows <sup>#3,#4</sup>                                                   | Defines settings for opening monitor windows.                                                                                                         |
|              |               | Email environment definition file (jimmail.conf)                                                               | A definition file that sets information necessary to send an email by using JP1/IM - Manager.                                                         |
|              |               | Display message change definition file (jcochmsg.conf) <sup>#3</sup>                                           | Defines the JP1 event conditions and new messages when changing the display of messages using the event display message change function.              |
|              |               | Display item definition file for a display message change definition (chmsg_attr_list.conf) <sup>#3</sup>      | Specifies the items to be displayed in the <b>Attribute name</b> display area of the Display Message Change Definition Settings window.               |
|              |               | Automatic input definition file for a display message change definition (chmsg_auto_list.conf) <sup>#3</sup>   | Specifies the conditions to be automatically set when the Display Message Change Definition Settings window opens.                                    |
|              |               | Environment definition file for events after the display message is changed (chmsgevent.conf)                  | Defines the behavior of the function for issuing an event when a display message is changed.                                                          |
|              | Central Scope | Host information file (jcs_hosts)                                                                              | Defines the host information that is managed by JP1/IM - Manager (Central Scope).                                                                     |
|              |               | Guide information file (jcs_guide.txt) <sup>#1</sup>                                                           | Defines guide information about the JP1 events that trigger a change in monitoring object status.                                                     |
|              |               | Settings file for the maximum number of status change events (evhist_warn_event_xxx.conf) <sup>#2</sup>        | Defines whether a JP1 event is to be issued when the number of status change events for a monitoring object exceeds a maximum value.                  |
|              |               | Settings file for the completed-action linkage function (action_complete_xxx.conf) <sup>#2</sup>               | Defines whether the completed-action linkage function is to be enabled.                                                                               |
|              |               | Definition file for automatic delete mode of status change event                                               | Defines whether the function that automatically deletes the status change events when a JP1 event's status becomes <b>Processed</b> is to be enabled. |
|              |               | Definition file for monitoring object initialization mode                                                      | Defines whether the function that initializes monitoring objects when a specific JP1 event is received is to be enabled.                              |

| Product name |                                            | Definition file name                                                                                                | Description                                                                                                                                                                                                               |
|--------------|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              |                                            | Automatic backup and recovery settings file for the monitoring object database (auto_dbbackup_xxx.conf)#2           | Defines whether the function that protects the monitoring object database from corruption caused by OS shutdown or cluster system switching during monitoring tree update processing is to be enabled.                    |
|              |                                            | Definition file for on memory mode of status change condition                                                       | Specifies whether the memory-resident status change condition function is to be enabled.                                                                                                                                  |
|              |                                            | System profile of Central Scope (jcs_sysprofile_xxx.def)#1                                                          | Common definition information for Central Scope viewer.<br>When you log in to Central Scope, this file is sent to Central Scope viewer.                                                                                   |
|              | IM Configuration Management                | Apply-IM-configuration-method definition file (jplcf_applyconfig.conf)                                              | Defines how to apply the system hierarchy.                                                                                                                                                                                |
|              |                                            | Host input information file (host_input_data.csv)                                                                   | An export file for host input information related to managed hosts of IM Configuration Management.                                                                                                                        |
|              |                                            | Collected host information file (host_collect_data.csv)                                                             | An export file for collected host information related to managed hosts of IM Configuration Management.                                                                                                                    |
|              |                                            | Profile management environment definition file (jplcf_profile_manager.conf)                                         | Defines information about the execution environment for the profile management function.                                                                                                                                  |
|              |                                            | Remote log trap environment definition file (jplcf_remote_logtrap.conf)                                             | Defines the execution environment for the remote-monitoring log file trap function and the remote-monitoring event log trap function.                                                                                     |
|              |                                            | Remote-monitoring log file-trap action definition file                                                              | Defines actions for the remote monitoring log trap function.                                                                                                                                                              |
|              |                                            | Remote-monitoring event log trap action-definition file                                                             | Defines actions for the remote monitoring event log trapping function.                                                                                                                                                    |
|              | IM database                                | Setup information file (jimdbsetupinfo.conf)                                                                        | Specifies setup information, such as the size of the IM database and the directory for storing data for the IM database, when the integrated monitoring database and IM Configuration Management database are set up.     |
|              |                                            | Cluster setup information file (jimdbclustersetupinfo.conf)                                                         | A file that describes the directory to store the size or data of the IM database for a logical host when the integrated monitoring database and IM Configuration Management database are set up in a cluster environment. |
|              | Intelligent Integrated Management Database | Intelligent Integrated Management Database setup information file (jimgnbsetupinfo.conf)                            | File that describes the items required when setting up Intelligent Integrated Management Database.                                                                                                                        |
|              |                                            | Cluster environment Intelligent Integrated Management Database setup information file (jimgnbclustersetupinfo.conf) | A File that describes the items required when setting up a clustered Intelligent Integrated Management Database environment.                                                                                              |
|              |                                            | Intelligent Integrated Management Database configuration file (postgresql.conf)                                     | File that describes the parameter definition for Intelligent Integrated Management Database (PostgreSQL).                                                                                                                 |

| Product name |                                    | Definition file name                                                                                                            | Description                                                                                                                                                                            |

|----------------|-------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JP1/IM - View  | Operation definition file of the IM Configuration Management - View ( <code>jcfview.conf</code> )           | This file specifies IM Configuration Management - View operation.                                                                                                                   |
|                | Communication environment definition file ( <code>view.conf.update</code> )                                 | Defines timeout periods for communication between JP1/IM - View and JP1/IM - Manager (Central Scope).                                                                               |
|                | Communication environment definition file ( <code>tree_view.conf.update</code> )                            | Defines timeout periods for communication between JP1/IM - View and JP1/IM - Manager (Central Scope).                                                                               |
|                | Non-encryption communication host configuration file ( <code>nosslhost.conf</code> )                        | Configures hosts that use non-encrypted communication.                                                                                                                              |
|                | IM-View settings file ( <code>tuning.conf</code> )                                                          | Defines the operation of JP1/IM - View, such as the number of connected-host log entries in the Login window and the operation when the Event Console window is displayed.          |
|                | Web page call definition file ( <code>hitachi_jp1_product-name.html</code> )                                | Used for calling another product's Web page from the Tool Launcher window.                                                                                                          |
|                | Start program definition file ( <code>!JP1_CS_APP0.conf</code> )                                            | Defines the start path for a program that is added to the toolbar in the Monitoring Tree window.                                                                                    |
|                | Toolbar definition file ( <code>!JP1_CS_FTOOL0.conf</code> )                                                | Defines the order of programs that are added to the toolbar in the Monitoring Tree window.                                                                                          |
|                | Icon operation definition file ( <code>!JP1_CS_FTREE0.conf</code> )                                         | Defines the operation of icons that are added to the toolbar in the Monitoring Tree window.                                                                                         |
|                | Configuration file for monitoring tree                                                                      | Defines the configuration of the monitoring tree that is displayed in the Monitoring Tree window.                                                                                   |
|                | Definition file for executing applications                                                                  | Defines the IDs and paths of applications that are executed by the viewer.                                                                                                          |
|                | Definition file for the Tool Launcher window                                                                | Defines the tree that is to be displayed in the Tool Launcher window.                                                                                                               |
|                | System profile of the Central Scope viewer ( <code>system.conf</code> )                                     | Central Scope Viewer common definition information.<br>Defines the Monitoring Tree (Editing) window and the Visual Monitoring (Editing) window.                                     |
|                | Performance report display definition file ( <code>performance.conf</code> )                                | Defines the function for displaying the performance report of the host that issued the event. This file defines the URL of the connection-target instance of JP1/PFM - Web Console. |
| JP1/IM - Agent | Alertmanager configuration file ( <code>jpc_alertmanager.yml</code> ) <sup>#3</sup>                         | A configuration file that defines the operation of Alertmanager.                                                                                                                    |
|                | Prometheus configuration file ( <code>jpc_prometheus_server.yml</code> ) <sup>#3</sup>                      | A configuration file that defines the operation of Prometheus server.                                                                                                               |
|                | Alert configuration file ( <code>jpc_alerting_rules.yml</code> ) <sup>#3</sup>                              | A File that defines the alert-evaluation rules that Prometheus server will Execute.                                                                                                 |
|                | Node exporter discovery configuration file ( <code>jpc_file_sd_config_node.yml</code> ) <sup>#3</sup>       | A File that Setup Node exporter that Prometheus server will scrape.                                                                                                                 |
|                | Process exporter discovery configuration file ( <code>jpc_file_sd_config_process.yml</code> ) <sup>#3</sup> | This file configures the Process exporter to be scraped by the Prometheus server.                                                                                                   |

| Product name | Definition file name                                                                                                                                                | Description                                                                                                                                                                          |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | Windows exporter discovery configuration file<br>(jpc_file_sd_config_windows.yml) <sup>#3</sup>                                                                     | A File that Setup Windows exporter that Prometheus server will scrape.                                                                                                               |
|              | Windows exporter (Hyper-V monitoring) discovery configuration file<br>(jpc_file_sd_config_windows_hyperv.yml) <sup>#3</sup>                                         | This file is used to set Windows exporter (Hyper-V monitoring) scrape by Prometheus server.                                                                                          |
|              | Node exporter for AIX discovery configuration file<br>(jpc_file_sd_config_node_aix.yml) <sup>#3</sup>                                                               | Files that set Node exporter for AIX that Prometheus server will scrape.                                                                                                             |
|              | Blackbox exporter (HTTP/HTTPS monitoring) discovery configuration file<br>(jpc_file_sd_config_blackbox_http.yml) <sup>#3,#5</sup>                                   | A File that Setup Blackbox exporter that Prometheus server will scrape for HTTP/HTTPS monitoring.                                                                                    |
|              | Blackbox exporter (HTTP/HTTPS monitoring) discovery configuration file (user-created)<br>(file_sd_config_blackbox_module-name-start-with-http.yml) <sup>#3,#5</sup> |                                                                                                                                                                                      |
|              | Blackbox exporter (ICMP monitoring) discovery configuration file<br>(jpc_file_sd_config_blackbox_icmp.yml) <sup>#3</sup>                                            | A File that Setup Blackbox exporter that Prometheus server will scrape for ICMP monitoring.                                                                                          |
|              | Blackbox exporter (ICMP monitoring) discovery configuration file (user-created)<br>(file_sd_config_blackbox_module-name-start-with-icmp.yml) <sup>#3,#5</sup>       |                                                                                                                                                                                      |
|              | Yet another cloudwatch exporter discovery configuration file<br>(jpc_file_sd_config_cloudwatch.yml) <sup>#3,#5</sup>                                                | A File that Setup Blackbox exporter that Prometheus server will scrape for ICMP monitoring.<br>A File that Setup Yet another cloudwatch exporter that Prometheus server will scrape. |
|              | Promitor discovery configuration file<br>(jpc_file_sd_config_promitor.yml) <sup>#3</sup>                                                                            | This file configures the Promitor to be scraped by the Prometheus server.                                                                                                            |
|              | OracleDB exporter discovery configuration file<br>(jpc_file_sd_config_oracledb.yml) <sup>#3</sup>                                                                   | Files that set OracleDB exporter that Prometheus server will scrape.                                                                                                                 |
|              | Script exporter discovery configuration file<br>(jpc_file_sd_config_script.yml) <sup>#3</sup>                                                                       | This file configures the Script exporter to be scraped by the Prometheus server.                                                                                                     |
|              | Web exporter discovery configuration file<br>(jpc_file_sd_config_web.yml) <sup>#3</sup>                                                                             | This file configures the Web exporter to be scraped by the Prometheus server.                                                                                                        |
|              | Web exporter discovery configuration file (user-created)<br>(file_sd_config_web_any-name.yml) <sup>#3,#5</sup>                                                      |                                                                                                                                                                                      |
|              | Web scenario file (any-name.spec.ts)                                                                                                                                | This file configures the Web exporter to be scraped by the Prometheus server.<br>This file describes Web scenarios used by Web scenario monitor feature.                             |
|              | VMware exporter discovery configuration file<br>(jpc_file_sd_config_vmware.yml) <sup>#3</sup>                                                                       | This file configures the VMware exporter to be scraped by the Prometheus server.                                                                                                     |
|              | SQL exporter discovery configuration file<br>(jpc_file_sd_config_mssql.yml) <sup>#3</sup>                                                                           | This file configures the SQL exporter to be scraped by the Prometheus server.                                                                                                        |

| Product name | Definition file name                                                                                                     | Description                                                                                                                                 |
|--------------|--------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|              | User-specific discovery configuration file ( <code>user_file_sd_config_any-name.yml</code> ) <sup>#3,#5</sup>            | A File that Setup Prometheus server to scrape. Exporter that you have prepared can also be subject to scrape.                               |
|              | Service definition file ( <code>jpc_program-name_service.xml</code> )                                                    | A WinSW definition file for make programs Windows-service in a Windows environment.                                                         |
|              | Unit definition file ( <code>jpc_program-name.service</code> )                                                           | A definition file for add programs to systemctl Add in a Linux.                                                                             |
|              | Windows exporter configuration file ( <code>jpc_windows_exporter.yml</code> ) <sup>#3</sup>                              | The configuration file that defines the operation of Windows exporter.                                                                      |
|              | Windows exporter (Hyper-V monitoring) configuration file ( <code>jpc_windows_exporter_hyperv.yml</code> ) <sup>#3</sup>  | The configuration file that defines the operation of Windows exporter (Hyper-V monitoring).                                                 |
|              | Process exporter configuration file ( <code>jpc_process_exporter.yml</code> ) <sup>#3</sup>                              | The configuration file that defines the operation of Process exporter.                                                                      |
|              | Blackbox exporter configuration file ( <code>jpc_blackbox_exporter.yml</code> ) <sup>#3</sup>                            | The configuration file that defines the operation of Blackbox exporter.                                                                     |
|              | Yet another cloudwatch exporter configuration file ( <code>jpc_ya_cloudwatch_exporter.yml</code> ) <sup>#3</sup>         | The configuration file that defines the operation of Yet another cloudwatch exporter.                                                       |
|              | Promitor Scraper configuration file ( <code>metrics-declaration.yaml</code> ) <sup>#3</sup>                              | The configuration file that defines the metrics to be acquired by the Promitor Scraper.                                                     |
|              | Promitor Scraper runtime configuration file ( <code>runtime.yaml</code> ) <sup>#3</sup>                                  | The configuration file that defines Promitor Scraper authentication information, ports used for scraping, and other information.            |
|              | Promitor Resource Discovery configuration file ( <code>resource-discovery-declaration.yaml</code> ) <sup>#3</sup>        | The configuration file that defines the resource group to be acquired by Promitor Resource Discovery.                                       |
|              | Promitor Resource Discovery runtime configuration file ( <code>runtime.yaml</code> ) <sup>#3</sup>                       | The configuration file that defines Promitor Resource Discovery authentication information, ports used for scraping, and other information. |
|              | Script exporter configuration file ( <code>jpc_script_exporter.yml</code> ) <sup>#3</sup>                                | The configuration file that determines the behavior of Script exporter.                                                                     |
|              | Web exporter configuration file ( <code>jpc_web_exporter.yml</code> ) <sup>#3</sup>                                      | The configuration file that defines the operation of Web exporter.                                                                          |
|              | Playwright configuration file ( <code>jpc_playwright.config.ts</code> ) <sup>#3</sup>                                    | The configuration file that defines the operation of Playwright.                                                                            |
|              | VMware exporter configuration file ( <code>jpc_vmware_exporter.yml</code> ) <sup>#3</sup>                                | The configuration file that defines the operation of VMware exporter.                                                                       |
|              | SQL exporter configuration file ( <code>jpc_sql_exporter.yml</code> ) <sup>#3</sup>                                      | The configuration file that defines the operation of SQL exporter.                                                                          |
|              | Sample file of Script exporter configuration file for SAP system monitoring ( <code>jpc_script_exporter_sap.yml</code> ) | This is a sample file of a configuration file that defines the operation of the Script Exporter for SAP system monitoring.                  |
|              | Log monitoring common definition file ( <code>jpc_fluentd_common.conf</code> ) <sup>#3</sup>                             | A File for defining Common behavior in fluentd, such as HTTP POST request function and log output function.                                 |

| Product name | Definition file name                                                                                             | Description                                                                                                                                                                                                                                               |
|--------------|------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | Log monitoring target definition file (jpc_fluentd_common_list.conf)#3                                           | A File that specifies what to monitor for logging. Specifies File of monitoring definition file, which is text-formatted log file, or Windows event-monitoring definition file. The logging monitoring of the specified definition File is set to Enable. |
|              | Monitoring text-formatted log file definition file (fluentd_@trapname@_tail.conf.template)#3,#5                  | A Definition File for monitoring text-formatted log File.                                                                                                                                                                                                 |
|              | Windows event log monitoring definition file (fluentd_@trapname@_wevt.conf.template)#3,#5                        | A Definition File for monitoring Windows event logs.                                                                                                                                                                                                      |
|              | Sample file of system log information monitoring definition file for SAP system (fluentd_sap_syslog_tail.conf)   | Sample file of the definition file for monitoring system log information of SAP system.                                                                                                                                                                   |
|              | Sample file of CCMS alert information monitoring definition file for SAP system (fluentd_sap_alertlog_tail.conf) | Sample file of the definition file used to monitor CCMS alerting for SAP system.                                                                                                                                                                          |
|              | Environment parameters file for jr3slget command (jr3slget.ini)                                                  | This file is used to set the output destination file name of the system log information of SAP system.                                                                                                                                                    |
|              | Sample file of environment parameters file for jr3slget command (jr3slget.ini.sample)                            | This file is used to set the output destination file name of the system log information of SAP system.                                                                                                                                                    |
|              | Environment parameters file for jr3alget command (jr3alget.ini)                                                  | This file is used to set the output-destination filename of CCMS alert information of SAP system.                                                                                                                                                         |
|              | Sample file of environment parameters file for jr3alget command (jr3alget.ini.sample)                            | This is a sample file of a file that sets the output destination file name of the CCMS alert information of the SAP system.                                                                                                                               |
|              | Log metrics definition file (fluentd_@name@_logmetrics.conf)#3#5                                                 | The Fluentd metric definition file used to read logs output by the application being monitored and convert them into log metrics.                                                                                                                         |
|              | Property label definition file (property_labels.conf)                                                            | The definition file used to convert IM management node property values into separate values.                                                                                                                                                              |
|              | imagent common configuration file (jpc_imagentcommon.json)                                                       | A configuration file defines Common operation of JP1/IM agent control base.                                                                                                                                                                               |
|              | imagent configuration file (jpc_imagent.json)                                                                    | A configuration file defines imagent operation of JP1/IM agent control base.                                                                                                                                                                              |
|              | imagentproxy configuration file (jpc_imagentproxy.json)                                                          | A configuration file defines imagentproxy operation of JP1/IM agent control base.                                                                                                                                                                         |
|              | imagentaction configuration file (jpc_imagentaction.json)                                                        | A configuration file defines imagentaction operation of JP1/IM agent control base.                                                                                                                                                                        |
|              | User-created definition file list definition file (jpc_user_deffile_list.json)#3                                 | A File that defines a user-created File that can be updated and delete with JP1/IM - Manager supplied REST API.                                                                                                                                           |
|              | Definition file property file (jpc_file_properties.json)                                                         | A File describes File name, File path, and File import operations for the definition File that are                                                                                                                                                        |

| Product name | Definition file name                                                                 | Description                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
|              |                                                                                      | to be manipulated by the acquisition or update functions of the definition File.                                                                     |
|              | Environment variable file (any file name) <sup>#3,#5</sup>                           | A File that defines an environment-variable for Execute commands on JP1/IM managed hosts.                                                            |
|              | Configuration file of the logical host new setup command (any-file-name)             | This is configuration file specified in the argument of the new setup command ( <code>jimalhsetup</code> command) for the logical host.              |
|              | Configuration file of the logical host version upgrade setup command (any-file-name) | This is configuration file specified in the argument of the version upgrade setup command ( <code>jimalhupdate</code> command) for the logical host. |

#1: The file name of the guide information file used in the system profile of Central Scope, and UNIX version of JP1/IM - Manager depend on the language used by the JP1/IM - Manager. The *xxx* part of the guide information file is explained later in the section describing details of each file.

#2: There are two settings files for the maximum number of status change events, two settings files for the completed-action linkage function, and two automatic backup and recovery settings files for the monitoring object database. Either `on` or `off` is set in *xxx*.

#3: A definition File that you can update using integrated operation viewer (for downloading and uploading a definition File) or REST API (for acquiring and updating a definition File). The following File can also be updated:

- File for Blackbox exporter  
CA certificate File, client certificate File, client certificate key File, Password File

#4: Definition File that can be specified in *User-created definition file list definition file (imdd\_user\_deffile\_list.json)*.

#5: Definition File that can be specified in *User-created definition file list definition file (jpc\_user\_deffile\_list.json)*. You can also specify the following File:

- File for Blackbox exporter  
CA certificate File, client certificate File, client certificate key File, Password File

## 2.2 Format of definition file

---

### ◆ Format of definition file explanations

This section describes the format of the definition file. Note that some of the items shown below might be omitted in some definition file explanations. Do not use any environment-dependent character in definition files or definition file names. Such a character might cause character corruption.

#### **Format**

Describes the format of the definition file.

#### **File**

Shows the name of the definition file.

#### **Storage directory**

Describes the definition file's storage location.

#### **Description**

Describes the use of the definition file.

#### **When the definitions are applied**

Describes when the definition file's contents are applied.

#### **Information that is specified**

Describes the information that is specified in the definition file.

#### **Example definition**

Provides an example of the definition file.

### ◆ Definition files for displaying user-defined event attributes

You can extend the functions for linking JP1/IM to other applications by customizing JP1/IM definition files.

#### **Customizing JP1/IM definition files**

Extending functions enables you to do the following:

- Display user-defined event attributes
- Display the monitor window from JP1 events displayed in JP1/IM - View
- Add new menus to the Tool Launcher window

*Note:*

If you use UTF-8 as the encoding to save a customized definition file, save the file without attaching a BOM (byte order mark).

For details about the functions, see *4.14 Displaying user-defined event attributes* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Overview of definition files

In a definition file, blocks that specify definitions are related to each other. Moreover, the definition files are related to each other. The following figure shows these relationships.

Figure 2–1: Relationships between definition blocks and definition files

Naming rules for definition files

The following shows the naming rules for definition files.

Table 2–2: Naming rules for definition files

| Definition file                               | Naming rule                                   |
|-----------------------------------------------|-----------------------------------------------|
| Definition file for extended event attributes | <i>company-name_product-name_attr_en.conf</i> |
| Definition file for object types              | <i>company-name_product-name_obj.en</i>       |
| Definition file for executing applications    | <i>company-name_product-name_app.conf</i>     |
| Definition file for opening monitor windows   | <i>company-name_product-name_mon.conf</i>     |
| Definition file for the Tool Launcher window  | <i>company-name_product-name_tree.conf</i>    |

Note that *product-name* may also be specified as *series-name\_product-name*. We recommend that for JP1 event issuance you use as the file name the value specified in `PRODUCT_NAME`, with the forward slash (/) replaced by the underscore (\_). Because `hitachi` is used as the default file name, use a name other than `hitachi` for *company-name*.

## Storage locations for definition files

The following shows the storage location for each definition file.

Table 2–3: Storage locations for definition files

| Definition file                               | Storage location                            |
|-----------------------------------------------|---------------------------------------------|
| Definition file for extended event attributes | Machine where JP1/IM - Manager is installed |
| Definition file for opening monitor windows   | Machine where JP1/IM - Manager is installed |
| Definition file for object types              | Machine where JP1/IM - Manager is installed |
| Definition file for executing applications    | Machine where JP1/IM - View is installed    |
| Definition file for the Tool Launcher window  | Machine where JP1/IM - View is installed    |

## Structures of definition files

This section provides information that is common to the JP1/IM definition files that can be customized in order to link with the Event Console window and Tool Launcher window.

The information provided in this section is applicable to the following three definition files:

- Definition file for extended event attributes
- Definition file for executing applications
- Definition file for the Tool Launcher window

The definition file for object types and the definition file for opening monitor windows have different structures.

## Components of definition files

The principal components of a definition file are the statement, blocks, and comments. A definition file begins with the statement that represents the attributes of the entire file (definition information header), followed by blocks that describe the details of the definition and any comments.

The following describes these components of a definition file.

## Statement

### *Structure of a statement*

A statement consists of multiple components that form a single meaning. A statement always begins at the beginning of a line and ends with a semicolon (;), followed by a linefeed code.

### *Types of statements*

Statements are classified as in-file statements and in-block statements.

#### *In-file statements*

An in-file statement indicates attributes of the definition file. There are two types of in-file statements: statements for the definition information header, and statements for block control. Each statement in a file is prefixed with @.

#### *In-block statements*

An in-block statement indicates attributes of a block. All statements that can be specified between the start-of-block statement (@define-block) and the end-of-block statement (@define-block-end) are in-block statements, except for comments. The in-block statements that can be specified depend on the block. In-block statements are not prefixed (i.e., there is no @).

## Block

### *Structure of a block*

A block consists of a set of statements. The set of statements includes a statement that declares the start of the block (@define-block), statements within the block that describe the actual definitions, comments, and a statement that declares the end of the block (@define-block-end).

Nested blocks are not allowed in a definition file.

### *Block type*

A block's type is specified in the type= parameter of the start-of-block statement (@define-block). For details about the types of blocks, see [@define-block statement](#).

### *Block priority*

A block contains a key item that must be unique within the definition. If the definition contains multiple key items, one of the blocks is selected according to a priority ranking. The block priorities are as follows:

1. Block in the last file when file names are sorted in ascending order
2. Last block specified in the file

In other words, when definition files are linked into a single file in ascending order of the file names, the last block in the linked file has priority.

## Comment

A comment is a line beginning with a hash mark (#) or a line consisting of only spaces, tabs, or a linefeed code. Comments do not contain definition information.

A comment is processed as a single statement. Because comments are evaluated by line, there is no need to delineate comments with a semicolon (;). If a comment ends with a semicolon (;), the semicolon is treated as part of the comment.

## Rules for generating common Statements

The two types of in-file statements are statements for the definition information header and statements for block control.

The following table lists and describes the in-file statements.

Table 2–4: List of in-file statements

| Statement name    | Description                                             | Type                                  |
|-------------------|---------------------------------------------------------|---------------------------------------|
| @file             | Declares the definition version.                        | For the definition information header |
| @product          | Declares program product information in the definition. | For the definition information header |
| @define-block     | Declares the beginning of a block.                      | For block control                     |
| @define-block-end | Declares the end of a block.                            | For block control                     |

In these statements, a statement for the definition information header defines attributes that are common to the entire definition file. The available statements for the definition information header depend on the definition file. The parameters for the statements for the definition information header also depend on the definition file.

A statement for block control is used to declare a block unit that is defined in the definition file. The rules for generating statements for block control are common to all definition files. These rules are described below.

For the rules for generating statements for the definition information header, see the descriptions of the individual definition files.

#### @define-block statement

##### Syntax

```
@define-block type="block-type";
```

##### Function

Declares the beginning of a block. Statements from this statement to the @define-block-end statement are treated as a single definition block.

##### Parameter

type="block-type"

Specifies the type of definition block. The following lists the block types that can be specified.

Table 2–5: List of block types

| Block name                              | Value in the parameter      |
|-----------------------------------------|-----------------------------|
| Event attribute definition block        | "event-attr-def"            |
| Event attribute group definition block  | "event-attr-group-def"      |
| Event display sequence definition block | "event-attr-order-def"      |
| Application execution definition block  | "application-execution-def" |
| Menu tree definition block              | "function-tree-def"         |

If an invalid block type is specified, the entire block is ignored and a warning is displayed, but file analysis processing continues.

##### Note:

Nested definition blocks are not allowed.

##### Example definition

See the description of the @define-block-end statement.

## @define-block-end statement

### Syntax

```
@define-block-end;
```

### Function

Declares the end of a definition block that begins with @define-block.

### Note:

If there is no corresponding @define-block statement, file analysis processing is canceled.

### Example definition

This example includes @define-block and @define-block-end statements:

```
@define-block type="event-attr-def";
block lang="English", platform="base", extended="false";
attr name="E.SEVERITY", title="Severity";
attr name="B.TIME", title="Registered time";
attr name="B.SOURCESERVER", title="Registration host";
attr name="E.USER_NAME", title="User name";
@define-block-end;
```

## ◆ Details of statements in definition files

This subsection lists the types and structures of and the values that can be specified in the statements that can be specified in some of the JP1/IM definition files.

### Note:

The information provided in this subsection is applicable only to the following three definition files:

- Definition file for extended event attributes
- Definition file for executing applications
- Definition file for the Tool Launcher window

## Types of statements

Table 2–6: Types of statements

| Statement category  | Statement types                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Structures of statements

Table 2–7: Structures of statements

| Statement type                                                        | Specification format                                                                                        |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Start-of-block statement                                              | @define-block type= <i>block-type</i>                                                                       |
| End-of-block statement                                                | @define-block-end                                                                                           |
| File attribute statement                                              | @file type= <i>definition-file-type</i> [, version= <i>definition-format-version</i> ]                      |
| Product statement                                                     | @product name= <i>product-name</i>                                                                          |
| Definition statement for function menu command options                | arguments= <i>command-arguments</i>                                                                         |
| Event attribute definition statement                                  | attr name= <i>attribute-name</i> , title= <i>display-item-name</i> [, type= <i>attribute-display-type</i> ] |
| Block attribute definition statement                                  | block lang= <i>language-type</i>  platform= <i>platform-type</i>  version= <i>version-in-use</i>            |
| Definition file for function menu execution definition identifiers    | execute_id= <i>application-execution-definition-identifier</i>                                              |
| Application description definition statement                          | description= <i>description-of-application-execution</i>                                                    |
| Group definition statement                                            | group name= <i>group-name</i> , attrs= <i>list-of-attribute-names</i>                                       |
| Function menu display icon definition statement                       | icon= <i>display-icon-file-name</i>                                                                         |
| Definition statement for application execution definition identifiers | id= <i>application-execution-definition-identifier</i>                                                      |
| Function menu identifier definition statement                         | id= <i>function-menu-identifier</i>                                                                         |
| Function menu display name definition statement                       | name= <i>display-name</i>                                                                                   |
| Sequence definition statement                                         | order id= <i>event-ID-definition-character-string</i> , attrs= <i>list-of-attribute-names</i>               |
| Function menu parent identifier definition statement                  | parent_id= <i>parent-function-menu-identifier</i>                                                           |
| Application path definition statement                                 | path= <i>command-path</i>                                                                                   |

## Rules for generating specification components in the statements

The table below lists the values that can be specified in the specification components of the statements.

Table 2–8: Values that can be specified in the specification components of the statements

| Specification components | Specifiable values     |
|--------------------------|------------------------|
| Hexadecimal characters   | From 0 to 9 and A to F |
| EUCJIS                   | EUCJIS                 |
| GB18030                  | GB18030                |
| JIS                      | JIS                    |

| Specification components                              | Specifiable values                                                                                                                                                                                       |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Shift-JIS                                             | SJIS                                                                                                                                                                                                     |
| UTF-8                                                 | UTF-8                                                                                                                                                                                                    |
| Description of application execution                  | User-defined character string of from 1 to 50 bytes                                                                                                                                                      |
| Application execution definition                      | <i>application-execution-definition</i>                                                                                                                                                                  |
| Application execution definition block                | <i>application-execution-def</i>                                                                                                                                                                         |
| Application execution definition identifier           | From 1 to 32 alphanumeric characters                                                                                                                                                                     |
| Event ID                                              | From 1 to 8 bytes of hexadecimal characters                                                                                                                                                              |
| Event ID definition character string                  | <i>event-ID   event-ID-definition-character-string enumeration-separator event-ID</i>                                                                                                                    |
| Event object type definition block                    | <i>event-object-def</i>                                                                                                                                                                                  |
| Event extended attribute definition                   | <i>extended-attributes-definition</i>                                                                                                                                                                    |
| Event attribute group definition block                | <i>event-attr-group-def</i>                                                                                                                                                                              |
| Event attribute definition block                      | <i>event-attr-def</i>                                                                                                                                                                                    |
| Event display sequence definition block               | <i>event-attr-order-def</i>                                                                                                                                                                              |
| Interface name                                        | From 1 to 32 alphanumeric characters                                                                                                                                                                     |
| Group name                                            | From 1 to 32 alphanumeric characters                                                                                                                                                                     |
| Command path                                          | File name                                                                                                                                                                                                |

## ◆ About definition of common placeholders for descriptive items in yaml file

The following is a general placeholder definition used in the description item of the .yaml file.

| Placeholder  | Definition                                                                                                                                                                                  |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <boolean>    | Indicates a Boolean value that can have either "true" or "false" values.                                                                                                                    |
| <duration>   | Indicates the duration that matches the following regular expressions: <code>((([0-9]+)y)?((([0-9]+)w)?((([0-9]+)d)?((([0-9]+)h)?((([0-9]+)m)?((([0-9]+)s)?((([0-9]+)ms)? 0)))))))))</code> |
| <filename>   | Indicates a valid path in the current working directory.                                                                                                                                    |
| <host>       | Indicates a valid string consisting of a host name or internet address and an optional port number.                                                                                         |
| <int>        | Indicates an integer value.                                                                                                                                                                 |
| <labelname>  | Indicates a string that matches the following regular expression: <code>[a-zA-Z_][a-zA-Z0-9_]*</code>                                                                                       |
| <labelvalue> | Indicates a Unicode string.                                                                                                                                                                 |
| <path>       | Indicates the path of a valid URL.                                                                                                                                                          |
| <scheme>     | Indicates a string that can use either "http" or "https" values.                                                                                                                            |
| <secret>     | Indicates a normal string that should be kept secret, such as a password.                                                                                                                   |
| <string>     | Indicates a regular string.                                                                                                                                                                 |

## ◆ Note on PromQL expression

- Performance data obtained by PromQL statements described in metric definition files and alert configuration files must have the following labels set for each type of SID in the configuration information (for CloudWatchSIDs other than EC2, for each AWS namespace).

For details about SID types of configuration information, see *3.15.6(1)(a) Type of SID of the target configuration and its available functions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Table 2–9: Label that must be set in the performance data retrieved by the PromQL statement

| Configuration information SID type | AWS namespace | Label that must be set in trend data (obtained with PromQL specified in promql in the metric definition file) | Label that must be set to alert (obtained with PromQL specified in expr in alert configuration file) |
|------------------------------------|---------------|---------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| Agent SID                          | --            | <ul style="list-style-type: none"> <li>instance</li> <li>job</li> <li>jp1_pc_nodelabel</li> </ul>             | <ul style="list-style-type: none"> <li>instance</li> <li>job</li> <li>jp1_pc_nodelabel</li> </ul>    |

| Configuration information SID type | AWS namespace | Label that must be set in trend data (obtained with PromQL specified in promql in the metric definition file) | Label that must be set to alert (obtained with PromQL specified in expr in alert configuration file)                                                                                          |
|------------------------------------|---------------|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    |               | <ul style="list-style-type: none"> <li>• jpl_pc_prome_hostname</li> </ul>                                     | <ul style="list-style-type: none"> <li>• jpl_pc_exporter</li> </ul>                                                                                                                           |
| Remote Agent SID                   |               |                                                                                                               | <ul style="list-style-type: none"> <li>• instance</li> <li>• job</li> <li>• jpl_pc_nodelabel</li> <li>• jpl_pc_exporter</li> <li>• jpl_pc_remote_monitor_instance</li> </ul>                  |
| CloudWatchSID for EC2              | AWS/EC2       |                                                                                                               | In addition to the common label# of CloudWatchSID, the following label is required. <ul style="list-style-type: none"> <li>• dimension_InstanceId</li> </ul>                                  |
| CloudWatchSID other than EC2       | AWS/DynamoDB  |                                                                                                               | In addition to the common label# of CloudWatchSID, the following label is required. <ul style="list-style-type: none"> <li>• dimension_TableName</li> </ul>                                   |
|                                    | AWS/Lambda    |                                                                                                               | In addition to the common label# of CloudWatchSID, the following label is required. <ul style="list-style-type: none"> <li>• dimension_FunctionName</li> </ul>                                |
|                                    | AWS/S3        |                                                                                                               | In addition to the common label# of CloudWatchSID, the following label is required. <ul style="list-style-type: none"> <li>• dimension_BucketName</li> <li>• dimension_StorageType</li> </ul> |
|                                    | AWS/SQS       |                                                                                                               | In addition to the common label# of CloudWatchSID, the following label is required. <ul style="list-style-type: none"> <li>• dimension_QueueName</li> </ul>                                   |
|                                    | AWS/States    |                                                                                                               | In addition to the common label# of CloudWatchSID, the following label is required. <ul style="list-style-type: none"> <li>• dimension_APIName</li> </ul>                                     |
| SIDs to monitor logs               | --            | <ul style="list-style-type: none"> <li>• instance</li> <li>• jpl_pc_nodelabel</li> </ul>                      | --                                                                                                                                                                                            |

#### (Legend)

--: N/A

#

The CloudWatchSID common label indicates the following labels:

- instance
- job
- jpl\_pc\_nodelabel
- jpl\_pc\_exporter
- account\_id
- region
- jpl\_pc\_remote\_monitor\_instance

- When narrowing down performance data using without clauses, by clauses, etc. in PromQL statements, perform the narrowing down so that the labels described in *Table 2-9 Label that must be set in the performance data retrieved by the PromQL statement* are not deleted.
- If an invalid PromQL statement is set in the promql of the metric definition file, the correct trend data will not be returned by the return trend data function.
- If an incorrect PromQL statement is set in expr in the alert configuration file, JP1 events may not be issued, extended attribute values may be blank, or JP1 events may not be associated with the correct IM management node.`jpc_file_sd_config_node.yml`

## 2.3 JP1/IM - Manager definition files (JP1/IM - Manager)

---

### ◆ Common definition settings file (changing the attribute of JP1 events)

#### Format

```
[JP1_DEFAULT\JP1CONFIG]
"ATTR_EVENT_LOGTRAP_SOURCEHOST"=dword:{00000000 | 00000001}
```

#### File

Use any file.

`jplim_jp1_event_attributes.conf.model` (model file for the common definition settings file (changing the attribute of JP1 events))

#### Storage directory

The storage directory of the model file for the common definition settings file (changing the attribute of JP1 events) is shown below. Copy the model file to create a new file, and give it any file name.

In Windows

*Manager-path*\conf

In UNIX

/etc/opt/jplimm/conf

#### Description

This file sets information about the source attribute of an event log trap as common definition information.

#### When the definitions are applied

When the `jbssetcnf` command is executed, information about the common definition settings file (changing the attribute of JP1 events) is registered as common definition information. Thereafter, when JP1/IM - Manager is restarted, the setting for the common definition information takes effect. If the common definition is changed, JP1/IM - Manager must be restarted.

#### Information that is specified

The following rules apply to the common definition settings file (changing the attribute of JP1 events):

- If # (0x23) is specified at the beginning of a line, the line is treated as a comment line.
- Do not enter a space or a tab before or after an equal sign (=) or a comma (, ), at the beginning of a line, or at the end of a line. If you do so, an error occurs when the `jbssetcnf` command is executed.
- A line containing only a linefeed is invalid.

```
[JP1_DEFAULT\JP1CONFIG]
```

Do not change this line.

```
"ATTR_EVENT_LOGTRAP_SOURCEHOST"=dword:{00000000 | 00000001}
```

Determines the JP1/Base event log trap to be monitored by JP1/IM - Manager, and the attribute to be mapped to the event source host name attribute of a JP1 event for a remote-monitoring event log trap.

Specify either 00000000 or 00000001. The default value is 00000000.

If 00000000 is specified, a computer name is mapped to the event source host name of the JP1 event (event ID = 3A71).

If 00000001 is specified, the event server name is mapped to the event source host name of the JP1 event (3A71).

In addition, the attribute of the event source host name is added to the JP1 event (3A71) for the remote-monitoring event log trap, and the monitored host name is displayed as the source host name.

For details about the attributes to be mapped to the event source host name of the JP1 event (3A71) for JP1/Base event log traps, see *14.3.10(2)(b) Changing JP1 event attributes (Setting for JP1/IM - Manager)* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

For details about the JP1 event (3A71) for the remote-monitoring event log trap, see *3.2.2(97) Details of event ID: 00003A71, or the event ID specified in the filter block of the remote-monitoring event log trap action-definition file*.

## ◆ Operation log definition file (imm\_operationlog.conf)

### Format

```
[logical-host-name\JP1IMM\OPERATION]
"ENABLE"=dword:hexadecimal-number
"LOGFILEDIR"="output-destination"
"LOGSIZE"=dword:hexadecimal-number
"LOGFILENUM"=dword:hexadecimal-number
```

### Files

imm\_operationlog.conf

imm\_operationlog.conf.model (model file for the operation log definition file)

### Storage directory

In Windows

*Manager-path*\conf

In UNIX

/etc/opt/jplimm/conf

### Description

This file specifies the common definition contents used by the operation log output function. Specify whether to output data to the operation log, the output destination and size of the operation log file, and the maximum number of log files that can be saved.

### When the definitions are applied

When the `jbssetcnf` command is executed, the settings in the operation log definition file (`imm_operationlog.conf`) are registered in the common definition information. After that, the settings in the common definition information take effect when JP1/IM - Manager is restarted. If you change the common definition, you must restart JP1/IM - Manager.

## Information that is specified

[*logical-host-name*\JP1IMM\OPERATION]

This entry indicates the key name of JP1/IM - Manager environment settings.

For the physical host, specify JP1\_DEFAULT for *logical-host-name*. For a logical host, specify its name for *logical-host-name*.

"ENABLE"=dword:*hexadecimal-number*

Specify (using a hexadecimal number) whether to enable operation log output. The system assumes the initial value if this item is not defined or if you specify a value other than the following:

- Initial value: 0x00000000
- To disable operation log output, specify 0x00000000.
- To enable operation log output, specify 0x00000001.

"LOGFILEDIR"="output-destination"

Specify (in absolute path format) the output destination of the operation log file (*imm\_operation.log*). The maximum length of the output destination is 217 bytes. Specify an existing write-enabled directory for the output destination. We recommend that for the operation log of a logical host, specify an output destination on the shared disk.

- Initial value  
In Windows: *Manager-path*\log\operationlog  
In UNIX: /var/opt/jplimm/log/operationlog
- Output destination example for a logical host:  
In Windows: *shared-folder*\JP1IMM\log\operationlog  
In UNIX: *shared-directory*/jplimm/log/operationlog

Network paths cannot be specified as the output destination.

If the execution environment is a Windows environment, the following character strings cannot be specified for the output destination:

- Character strings that contain colons (:), question marks (?), double quotation marks ("), left angle brackets (<), right angle brackets (>), or vertical bars (|)
- Any of the following character strings (not case sensitive):  
CON, PRN, AUX, NUL, COM1, COM2, COM3, COM4, COM5, COM6, COM7, COM8, COM9, LPT1, LPT2, LPT3, LPT4, LPT5, LPT6, LPT7, LPT8, or LPT9

"LOGSIZE"=dword:*hexadecimal-number*

Specify (by using a hexadecimal number in megabytes) the size of the operation log file (*imm\_operation.log*) by using a hexadecimal number. The system assumes the initial value if this item is not defined or if you specify a value outside the specifiable range.

- Initial value: 0x00000005 (5 MB)
- Specifiable range: 0x00000001 to 0x00000800 (1 MB to 2,048 MB)

"LOGFILENUM"=dword:*hexadecimal-number*

Specify (using a hexadecimal number) the maximum number of operation log files (*imm\_operation.log*) that can be saved. The system assumes the initial value if this item is not defined or if you specify a value outside the specifiable range.

- Initial value: 0x0000000A (10 files)
- Specifiable range: 0x00000001 to 0x00000010 (1 to 16 files)

## Example definition

The following shows an example of the operation log definition file for setting the log file size to 5 MB and for setting the maximum number of files that can be saved to 10. Note that the definition example shown below applies when JP1/IM - Manager is installed on a physical host whose OS is UNIX.

```
[JP1_DEFAULT\JP1IMM\OPERATION]
"ENABLE"=dword:00000001
"LOGFILEDIR"="/var/opt/jplimm/log/operationlog"
"LOGSIZE"=dword:00000005
"LOGFILENUM"=dword:0000000A
```

## 2.4 JP1/IM - Manager definition files (Intelligent Integrated Management Base)

### ◆ Intelligent Integrated Management Base definition file (imdd.properties)

#### Format

```
server.port=port-number
jpl.imdd.proxy.server[n].host=host-name-of-proxy-server[n]
jpl.imdd.proxy.server[n].port=port-number-of-proxy-server[n]
jpl.imdd.proxy.server[n].user=authentication-user-ID-of-proxy-server[n]

## Files

imdd.properties

imdd.properties.model (model file for the Intelligent Integrated Management Base definition file)

## Storage directory

In Windows

For a physical host:

*Manager-path*\conf\imdd\

For a logical host:

*shared-folder*\jplimm\conf\imdd\

In UNIX

For a physical host:

/etc/opt/jplimm/conf/imdd/

For a logical host:

*shared-folder*/jplimm/conf/imdd/

## Description

This file defines system settings for the Intelligent Integrated Management Base.

## When the definitions are applied

The specified definitions take effect when JP1/IM - Manager starts.

## Information that is specified

The following rules apply to the Intelligent Integrated Management Base definition file:

- If # (0x23) is specified at the beginning of a line, the line is treated as a comment line.
- Property names are case sensitive.
- The definition file must be saved in UTF-8 without BOM (byte order mark).
- If an invalid property is found, the system ignores the line to continue.
- We cannot guarantee the behavior when a property is set to an unacceptable value.

`server.port=port-number`

Specifies a port number on which the Intelligent Integrated Management Base will receive HTTP connections. The specified port number must be unique across the system and across the host that is created during the setup. Acceptable values are from 5001 to 65535. The default value is 20703.

`jp1.imdd.proxy.server[n].host=host-name-of-proxy-server[n]`

Specifies the host name of proxy server [n].

The specified host name of the proxy server must be able to be resolved. If an invalid host name is specified, product plug-ins fail to execute APIs.

Use ASCII characters to specify it.

If you specify this property multiple times, use serial numbers starting from 0 for [n].

`jp1.imdd.proxy.server[n].port=port-number-of-proxy-server[n]`

Specifies the port number of proxy server [n].

Possible values are 1 to 65535. If the specified value is beyond the range of the possible values, the KAJY52016-W message is output and the proxy server [n] setting is disabled.

If you specify this property multiple times, use serial numbers starting from 0 for [n].

`jp1.imdd.proxy.server[n].user=authentication-user-ID-of-proxy-server[n]`

Specifies the user ID of the authentication user for proxy server [n].

If you use proxy server authentication, you must specify this option and configure authentication information for the proxy server. For details about the authentication information settings for the proxy server, see [jddsetproxyuser](#) in *Chapter 1. Commands*.

If you specify this property multiple times, use serial numbers starting from 0 for [n].

If you do not use proxy server authentication, you can omit this option.

`jp1.imdd.proxy.target[n].host=target-host[n]-of-REST-API-that-uses-proxy-server`

Specifies the host for target [n] that is a target of REST API which uses the proxy server. The host name of target [n] must have the host section in the URL of the REST API.

For example, if the REST API has the `http://hitachi.co.jp/api/v1/restApi` value, specify `hitachi.co.jp`.

Use ASCII characters to specify it.

If you specify this property multiple times, use serial numbers starting from 0 for [n].

`jp1.imdd.proxy.target[n].serverHost=target-host-name[n]-of-destination-proxy-server`

Specifies the host name of proxy server [n] working as the destination.

If the specified value is not configured for proxy server [n] or is invalid, the KAJY52018-W message is output and the settings for target host [n] are disabled.

Use ASCII characters to specify it.

If you specify this property multiple times, use serial numbers starting from 0 for [n].

`jp1.imdd.gui.settings.contentView.<custom UI Id>.title=title-displayed-on-custom-UI-tab`

Specifies the title displayed on the custom UI tab when the custom UI display function is used.

The title must be a string with 255 or fewer characters that contains neither control nor machine-dependent characters.

If you use multi-byte characters, convert them into Unicode format (which is expressed as `\udddd`). In this case, the number of characters is counted as the number of them converted into Unicode.

You must specify this option for every `<custom UI Id>`.

`jpl.imdd.gui.settings.contentView.<custom UI Id>.url=path-to-html-file-displayed-in-user-defined-window-display-area`

Specifies the path to the html file displayed in **User-defined window display area** in relative path format to `public` when the custom UI display function is used. The html file is located in the following location:

In Windows

`Manager-path\public\customUI\`

In UNIX

`/opt/jplimm/public/customUI/`

Specify the path to the html file as a string with 255 or fewer characters that contains neither control nor machine-dependent characters. Use a forward slash (/) as a delimiter.

If you use multi-byte characters, convert them into Unicode format (which is expressed as `\udddd`). In this case, the number of characters is counted as the number of them converted into Unicode. You do not have to enclose a space character ( ) with double quotation marks (").

You must specify this option for every `<custom UI Id>`.

`jpl.imdd.gui.settings.contentView.<custom UI Id>.sid=tree-SID-of-IM-management-node-on-which-user-defined-windows-are-displayed`

Specifies the tree SID of the IM management node on which user-defined windows are displayed when the custom UI display function is used.

The tree SID of the IM management node you specify must have 1,048,576 or less characters. The characters allowed conform to the specifications of the tree SID specified.

You can use regular expressions when specifying the tree SID of an IM management node. The regular expressions work if they match perfectly. The condition will be true if the specified regular expression matches perfectly with the whole string of the tree SID of the IM management node after comparing the expression with the string. When regular expressions are used, it may take time for searching if `.*`, which matches any string, is used many times. If you want to use `.*`, do so only when it is really necessary.

Note that the system does not check whether the specified tree SID exists.

You must specify either `sid` or `target` for every `<custom UI Id>`.

`jpl.imdd.gui.settings.contentView.<custom UI Id>.target=SID-of-IM-management-node-on-which-user-defined-windows-are-displayed`

Specifies the tree SID of the IM management node on which user-defined windows are displayed when the custom UI display function is used.

The tree SID of the IM management node you specify must have 1,048,576 or less characters. The characters allowed conform to the specifications of the tree SID specified. You can use regular expressions when specifying the SID of an IM management node. The regular expressions work if they match perfectly. The condition will be true if the specified regular expression matches perfectly with the whole string of the SID of the IM management node after comparing the expression with the string. When regular expressions are used, it may take time for searching if `.*`, which matches any string, is used many times. If you want to use `.*`, do so only when it is really necessary.

Note that the system does not check whether the specified tree SID exists.

You must specify either `sid` or `target` for every `<custom UI Id>`.

`jpl.im.db.DEFAULT.portNo=port-number-used-by-IM-database`

Specifies the port number used by the IM database.

For a physical host, use the value specified for the `IMDBPORT` option in the setup information file that is used during setup of the integrated monitoring database. If the `IMDBPORT` option is set to its default, you do not have to specify the `jpl.im.db.DEFAULT.portNo` value.

For details about the setup information file, see [Setup information file \(jimdbsetupinfo.conf\)](#).

For a logical host, use the value specified for the `IMDBPORT` option in the cluster setup information file that is used during setup of the integrated monitoring database.

For details about the cluster setup information file, see [Cluster setup information file \(jimdbclustersetupinfo.conf\)](#).

`jp1.im.db.DEFAULT.logicalHostNum=number-used-by-IM-database-for-logical-host-to-identify-logical-host`

Specifies the number used by the IM database for a logical host to identify the host.

Specify the value used for the `LOGICALHOSTNUMBER` option in the cluster setup information file that is used during setup of the integrated monitoring database.

If a logical host is specified for `jp1.im.db.DEFAULT.portNo`, specify this option.

For details about the cluster setup information file, see [Cluster setup information file \(jimdbclustersetupinfo.conf\)](#).

`jp1.imdd.gui.settings.linkedUnit.impact.unknownDisplay=whether-to-show/hide-impact-unknown-icon`

Specifies whether to show an icon indicating that it is unknown whether there is any impact on following root jobnets ( ? icon) in the **Job flow** tab and the Linked unit dialog box.

Specify either `true` or `false`. Use `true` if you want to show the icon, or `false` if not. The default value is `true`.

`jp1.imdd.event.stormCompatible=Compatible-setting-of-the-repeated-event-viewing-suppression-function`

In version 12-00, repeated-event display is not suppressed even if the `-storm` option of the `jcoimdef` command is set to `ON`. Therefore, if you upgraded from version 12-00, to use the repeated event viewing suppression function, the compatible setting of the Repeated event viewing suppression function must be disabled (`false`).

If you new install a version 12-10 or later, the compatible setting of the repeated event viewing suppression Function is setting to Disabled (`false`) beforehand.

Specify either `true` or `false`.

If you set it to `true`, display of repeated events is not suppressed just like in 12-00. If you set it to `false`, display of repeated events is suppressed.

The default value is `true`.

The repeated-event display suppression function is enabled when suppression of repeated event monitoring in the `-storm` option of the `jcoimdef` command is set to `ON` and the `jp1.imdd.event.stormCompatible` option is set to `false`.

The repeated-event display suppression function is disabled when suppression of repeated event monitoring in the `-storm` option of the `jcoimdef` command is set to `OFF`, regardless of the `jp1.imdd.event.stormCompatible` option.

`jp1.imdd.gui.settings.eventSearchCount=number-of-searches-in-event-acquisition`

Specifies the number of searches during event acquisition that is performed by the integrated operation viewer to show the event list.

In event acquisition, the system searches for events mapped with the selected IM management node. Depending on the pages to be displayed, the search start position, search direction, and 100 events to be searched for are determined. If 100 events cannot be obtained due to an event receiver filter, the search is repeated for the next 100 events.

You specify the upper limit for the number of these repeated event searches. If the number of searches reaches the specified value, the search operation is interrupted and the events obtained before the interruption are displayed in the event list.

Possible values are 0 to 120000 (times). The number of times is unlimited if you specify 0 for it. The default is 10. If a value beyond the possible values is specified, the default value is assumed for operation.

`jp1.imdd.authBasic=whether-to-enable/disable-Basic-authentication`

In any REST API of the Intelligent Integrated Management Base, you can use an authentication method with login information added to the REST API (Basic authentication). This option specifies whether to enable the Basic authentication.

Specify either `true` or `false`.

The Basic authentication is enabled if the option is set to `true`.

The default is `false`.

For details about the REST API, see [5. API](#).

`jp1.imdd.jp1LoginForm=true|false`

Specifies whether the login form for JP1/Base authentication is displayed as the login window of the Intelligent Integrated Management Base.

When no OpenID provider is defined, the option assumes `true` for operation if it is set to `false`.

Furthermore, if it is set to `false` and only one OpenID provider is defined, the authentication URL of the OpenID provider is called directly without the use of the authentication window of the Intelligent Integrated Management Base.

Specify either `true` or `false`.

The JP1/Base authentication login form is enabled if the option is set to `true`.

The default is `true`.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.client-name=alias-name-of-the-client`

Specifies the alias name of the Intelligent Integrated Management Base client registered in the OpenID provider.

The alias name of the client is used as the name of the button on the login window of the Intelligent Integrated Management Base.

Specify a unique name with which the OpenID provider can be identified for `<key-name-of-the-OpenID-provider>`.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.client-id=client-ID-configured-in-the-OpenID-provider`

Specifies the ID of the Intelligent Integrated Management Base client registered in the OpenID provider.

Specify a unique name with which the OpenID provider can be identified for `<key-name-of-the-OpenID-provider>`.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.client-authentication-method=basic|post`

Specifies the authentication method used on the server that authorizes the Intelligent Integrated Management Base client registered in the OpenID provider.

Specify either `basic` or `post`.

The default is `basic`.

Specify a unique name with which the OpenID provider can be identified for `<key-name-of-the-OpenID-provider>`.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.authorization-grant-type=authorization_code`

Specifies the type of authorization granted to the Intelligent Integrated Management Base client registered in the OpenID provider.

Specify `authorization_code`.

Specify a unique name with which the OpenID provider can be identified for `<key-name-of-the-OpenID-provider>`.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.redirect-uri=URI-of-the-redirection-URL`

Specifies the URI of the redirection URL registered in the OpenID provider in the following format:

```
<Intelligent-Integrated-Management-Base-login-URI>/oauth2/code/<OpenID-provider>
```

Example:

```
https://IMHOST:20703/login/oauth2/code/okta
```

Specify a unique name with which the OpenID provider can be identified for *<key-name-of-the-OpenID-provider>*. The permitted characters are a URL-formatted string. If the characters are specified in any other format, the KAJY52019-W message is output to disable the OpenID provider settings and the startup of the JP1/IM3-Manager service continues.

The authentication request is stored in the WWW browser and in the session of the Intelligent Integrated Management Base. Cookie data is managed on a domain basis. Therefore, make sure that the Intelligent Integrated Management server host name for the Intelligent Integrated Management Base login URI matches that for the URI of the redirection URL, and make sure that during authentication processing, the cookies are not removed or overwritten.

Also, if the Intelligent Integrated Management server host name for the Intelligent Integrated Management Base login URI and that for the URI of the redirection URL do not match, the KAJY52028-E message is output as a return value to the integrated operation viewer or REST API upon login by OpenID authentication.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.scope=scope-used-for-the-client`

Specifies the scope used for the Intelligent Integrated Management Base client registered in the OpenID provider. To specify multiple scopes, separate them with a comma ( , ).

Specify a unique name with which the OpenID provider can be identified for *<key-name-of-the-OpenID-provider>*. The permitted characters are ASCII characters (0x21, 0x23 to 0x5B, and 0x5D to 0x7E). If any characters that are not permitted are specified, the KAJY52019-W message is output to disable the OpenID provider settings and the startup of the JP1/IM3-Manager service continues.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.authorization-uri=URI-of-the-authorization-URL`

Specifies the URI of the authorization URL.

Specify a unique name with which the OpenID provider can be identified for *<key-name-of-the-OpenID-provider>*. If a value that is not in the URL format is specified, the KAJY52019-W message is output to disable the OpenID provider settings and the startup of the JP1/IM3-Manager service continues.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.token-uri=URI-of-the-URL-from-which-the-token-is-obtained`

Specifies the URI of the URL from which the token is obtained.

If a value that is not in the URL format is specified, the KAJY52019-W message is output to disable the OpenID provider settings and the startup of the JP1/IM3-Manager service continues.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.user-info-uri=URI-of-the-user-information-URL`

Specifies the URI of the user information URL.

Specify a unique name with which the OpenID provider can be identified for *<key-name-of-the-OpenID-provider>*. If a value that is not in the URL format is specified, the KAJY52019-W message is output to disable the OpenID provider settings and the startup of the JP1/IM3-Manager service continues.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.userNameAttribute=attribute-name`

Specifies the name of the attribute used to access the name of the user based on the user information response.

Specify a unique name with which the OpenID provider can be identified for *<key-name-of-the-OpenID-provider>*.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.jwk-set-uri=URI-of-the-JSON-Web-Key-(JWK)-Set-URL`

Specifies the URI of the JSON Web Key (JWK) Set URL.

Specify a unique name with which the OpenID provider can be identified for *<key-name-of-the-OpenID-provider>*. If a value that is not in the URL format is specified, the KAJY52019-W message is output to disable the OpenID provider settings and the startup of the JP1/IM3-Manager service continues.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.issuer-uri=Issuer-Identifier-of-the-OpenID-provider`

Specifies the Issuer Identifier of the OpenID provider.

Specify a unique name with which the OpenID provider can be identified for *<key-name-of-the-OpenID-provider>*. If a value that is not in the URL format is specified, the KAJY52019-W message is output to disable the OpenID provider settings and the startup of the JP1/IM3-Manager service continues.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.logout-uri=logout-URI-of-the-OpenID-provider`

Specifies the logout URL of the OpenID provider.

Specify a unique name with which the OpenID provider can be identified for *<key-name-of-the-OpenID-provider>*.

If a value that is not in the URL format is specified, the KAJY52019-W message is output to disable the OpenID provider settings and the startup of the JP1/IM3-Manager service continues.

`jp1.imdd.oidc.<key-name-of-the-OpenID-provider>.introspect-uri=token-information-acquisition-URI-of-the-OpenID-provider`

Specifies the token information acquisition URL of the OpenID provider.

Specify a unique name with which the OpenID provider can be identified for *<key-name-of-the-OpenID-provider>*.

If a value that is not in the URL format is specified, the KAJY52019-W message is output to disable the OpenID provider settings and the startup of the JP1/IM3-Manager service continues.

`jp1.imdd.simt.updateMode=reconfigure|change`

Specifies the default method for application when the `jddupdatetree` command is executed.

Specify either `reconfigure` or `change`.

If you specify `reconfigure`, the application is performed in the new and rebuilding mode, which is the same as version 12-10 or earlier. If you specify `change`, the application is performed in the configuration change mode.

The default value is `change`.

If this option is not defined, it assumes `reconfigure`. If an invalid value is specified, the option uses the default value, `change`.

`jp1.imdd.trenddata.deleteInterval=Interval-for-deleting-trend-data-or-JP1/IM-agent-information`

Set the interval for trend data deletions or trend data deletions by JP1/IM agent information deletion.

For the interval, specify the period from when you delete trend data and restart the trend data management service until the next trend data deletion or the start of trend data deletion due to JP1/IM agent information deletion. The interval range is 1 to 172,800 (seconds).

If the value that is specified is outside the permitted value range or there is no definition, the default value (1 second) is assumed.

For details on the values to be set, see 1. of *Notes on Delete trend data* in 2.7.2(3)(g) *Deleting Trend Data Manually (Specify integrated agent, user-defined Prometheus, and user-defined Fluentd host names and Delete)* in JP1/Integrated Management 3 - Manager Overview and System Design Guide.

`jp1.imdd.http.adminAllowUserDashboard = enable/disable-the-dashboard-get/list-collection/deletion-function-for-administrators`

Sets whether to enable the dashboard-get/list collection/deletion function for administrators. For details about the Admin dashboard-get/list collection/deletion feature, see 3.2.4 *Dashboard Import / Export Function and Expanded Delete Function* in JP1/Integrated Management 3 - Manager Overview and System Design Guide.

Specify either `true` or `false`.

When `true` is set, the dashboard-get/list collection/deletion function for administrators is enabled.

The default when a new installation is performed is `true`. If a character other than `true` or `false` is specified, and this property is not specified, `false` is assumed.

Defaults to `false`.

## Notes

When the Intelligent Integrated Management Base service starts, if this definition file does not exist or an attempt to read the file fails, the following behavior occurs.

For a physical host:

The KAJY00015-W message is output to the integrated trace log, the default value is tentatively set for the property, and the service starts.

For a logical host:

The KAJY00021-E message is output to the integrated trace log, and the Intelligent Integrated Management Base service ends.

## Files

imdd\_systemnode.conf

`imdd_systemnode.conf.model` (model file for the system node definition file)

## Storage directory

In Windows

For a physical host:

`Manager-path\conf\imdd\`

For a logical host:

`shared-folder\jplimm\conf\imdd\`

In UNIX

For a physical host:

`/etc/opt/jplimm/conf/imdd/`

For a logical host:

`shared-directory/jplimm/conf/imdd/`

## Description

This setting file defines the hierarchical structure of the system to represent it in a sunburst or tree chart, and sorts collected data into different groups of defined hosts or other object root nodes.

It defines in what system each host or other object root node in the configuration information collected by the Intelligent Integrated Management Base is located.

Displayed items include hosts and other object root nodes in the agent configuration or remote monitoring configuration of JP1/IM - Manager and any node contained in the configuration information collected from other products. If the AJS manager or PFM manager is included in the linking host of JP1/IM - Manager (Intelligent Integrated Management Base), child AJS agents and PFM monitoring agents are also displayed in the tree.

The list of hosts and other object root nodes is obtained when the `jddcreatetree` command is executed, and the hosts and other object root nodes are allocated under the system according to the system node definition file (`imdd_systemnode.conf`) to create the hierarchical structure. Therefore, even a host or other object root node defined in the system node definition file (`imdd_systemnode.conf`) is not displayed in the tree if it is not found in the configurations of JP1/IM, JP1/AJS, or JP1/PFM.

If one node is used in more than one system or subsystem, the host must be defined to be included in one of those systems. One node cannot be managed by more than one system.

## When the definitions are applied

The settings in the system node definition file are applied to the Intelligent Integrated Management Base when the `jddcreatetree` and `jddupdatetree` commands are completed successfully.

For details about the `jddcreatetree` and `jddupdatetree` commands, see [jddcreatetree](#) and [jddupdatetree](#) in *Chapter 1. Commands*.

## Information that is specified

The system node definition file must be saved in UTF-8 without BOM (byte order mark). If you specify a backslash (\) as part of a character string, immediately before \, specify \ as an escape character.

"version": "2"

Specifies the version of the system node definition file. Set this to 2. This option is mandatory.

"id": "nth-system-name-(ID)"

Specifies a system ID to be set in the SID (a unique ID representing a component of a linked product) with alphanumeric characters. `id` can be up to 255 characters in length. The total maximum number of systems and system components that you can specify is 1,000. This option is mandatory.

- For a system:

The value must be unique across systems directly under `allSystem`.

- For a subsystem:

The value must be unique across subsystems directly under `children`.

To merge the system node definition files due to system consolidation, check for the uniqueness of the identifiers and change the `id` values if necessary.

"displayName": "system-name-to-be-displayed"

Specifies the name of the system that will appear in a sunburst or tree chart.

The name can be up to 255 characters in length and must not include any control characters or machine-dependent characters. The value of `displayName` does not have to be unique in the system node definition file. It can be used multiple times.

"jplResourcesGroup": "JPL-resource-group"

Specifies a JP1 resource group to indicate an area to be monitored by the system. This field is not required unless you want to use JP1 resource groups to control access.

The value of `jplResourcesGroup` can be up to 64 characters in length and can include alphanumeric characters and the following symbols: exclamation mark (!), at mark (@), hash mark (#), dollar sign (\$), percent sign (%), ampersand (&), underscore (\_), hyphen (-), asterisk (\*), single quotation mark ('), caret (^), left curly bracket ({), right curly bracket (}), left parenthesis ( ( ), right parenthesis ( ) ), period ( . ), backslash (\), grave accent mark (`), and tilde (~).

"hostName": [ { "host-name-string": "type" } . . . ]

Specifies a list of hosts in the IM configuration and hosts that belong to the system, such as registration agents for linked products, with a combination of a host name string and type as follows.

| Host name string                                     | Type (6 or less characters) |
|------------------------------------------------------|-----------------------------|
| Specify a host name directly                         | "" (Empty string)           |
| Specify hosts using regular expressions <sup>#</sup> | regexp                      |

<sup>#</sup> For the regular expression, use an extended regular expression. The regular expressions work if they match perfectly. The condition will be true if the specified regular expression matches perfectly with the whole string of the host name after comparing the expression with the string. For details about regular expressions, see *Appendix G. Regular Expressions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

The host name can be up to 255 characters in length and can include alphanumeric characters and the following symbols: exclamation mark (!), dollar sign (\$), left parenthesis ( ( ), right parenthesis ( ) ), asterisk (\*), plus sign (+), comma ( , ), hyphen (-), period ( . ), forward slash (/), colon ( : ), left angle bracket (<), equal sign (=), left square bracket ([), backslash (\), right square bracket (]), caret (^), left curly bracket ({), vertical bar (|), and right curly bracket (}).

Example:

```
"hostName": [ { "host1": "" }, { ".+[1-5]": "regexp" } ]
```

The list of hosts specified in `hostName` is used to group data. The grouping proceeds from the top to the bottom of the list and handles host names case-insensitively. If a subsystem is not defined and `type` and `name` are not specified by `children`, this option cannot be omitted.

If duplicate host names are found, the second and further occurrences of the host name are ignored.

#### "objectRoot"

Specifies the object root node type, object root node string, and type of an object root node that belongs to a system or subsystem.

#### "type": "*object-root-node-type*"

Specifies the type of the object root node name specified as `name`.

The specified object root node type is not case sensitive. For details about values that can be specified for `type`, see the manual for each product. You can specify only the value of `HOST` when JP1/AJS or JP1/PPM is linked.

If a subsystem is not defined by `children` and `hostName` is not specified, this option cannot be omitted.

You can specify single-byte alphanumeric characters and symbols including hyphen (-), period (.), colon (:), and tilde (~) as `type`.

#### "name": [{"*object-root-node-string*": "*type*" } . . . ]

Specifies the object root node string and type of an object root node that belongs to the system or a subsystem as follows.

| Object root node string                              | Type              |
|------------------------------------------------------|-------------------|
| Specify an object root node string directly          | "" (Empty string) |
| Specify hosts using regular expressions <sup>#</sup> | regexp            |

<sup>#</sup> For the regular expression, use an extended regular expression. The regular expressions work if they match perfectly. The condition will be true if the specified regular expression matches perfectly with the whole string of the object root node name after comparing the expression with the string. For details about regular expressions, see *Appendix G. Regular Expressions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Example 1:

```
"name": {"switch1": ""}
```

Example 2:

```
"name": { ".+[1-5]+": "regexp" }
```

The list of object root nodes specified in `name` is used to group data. The grouping proceeds from the top to the bottom of the list and handles object root nodes case-insensitively. If the object root node name specified for `name` and the object root node type specified for `type` are duplicated, the second and subsequent object root node names are ignored.

If a subsystem is not defined by `children` and `hostName` is not specified, this option cannot be omitted.

#### "children"

Specifies a list of subsystems that are directly under the system with the values of the fields from `id` to `children` to define a hierarchical structure. A hierarchical structure can have up to 10 levels including the top system. The `children` field is not required unless the system has subsystems directly under itself.

For details about hierarchical structures that can be represented in a sunburst or tree chart in the integrated operation viewer, see the section describing the hierarchical structure of a sunburst or tree chart in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## Example definition 1

### Definition of the example configuration

To define a structure that includes systems, subsystems, and their hosts described in the following figure:

### Example configuration

```
{
  "meta":{
    "version":"2"
  },
  "allSystem":[
    {
      "id":"systemA",
      "displayName":"System A",
      "jplResourcesGroup":"SYSTEM_A",
      "hostName":[{"HOST-A0":""}],
      "children":[
```

```

{
  "id": "subA1",
  "displayName": "System A-1",
  "jplResourcesGroup": "SYSTEM_A",
  "hostName": [{"HOST-A10": ""}, {"HOST-A11": ""}]
},
{
  "id": "subA2",
  "displayName": "System A-2",
  "jplResourcesGroup": "SYSTEM_A",
  "children": [
    {
      "id": "subA21",
      "displayName": "System A-2-1",
      "jplResourcesGroup": "SYSTEM_A",
      "hostName": [{"^HOST-A21.*": "regex"}, {"HOST-A10-1": ""}]
    },
    {
      "id": "subA22",
      "displayName": "System A-2-2",
      "jplResourcesGroup": "SYSTEM_A",
      "hostName": [{"HOST-A22": ""}]
    }
  ]
}
],
{
  "id": "systemB",
  "displayName": "System B",
  "jplResourcesGroup": "SYSTEM_B",
  "hostName": [{"HOST-B10": ""}, {"HOST-B11": ""}]
}
]
}

```

## Example definition 2

*Definition of a configuration where one host and root object node are used in more than one system or subsystem*

As one host cannot be managed by more than one system, the host must be defined to be included in either System A or System B.

*Example configuration*

```

{
  "meta": {
    "version": "1"
  },
  "allSystem": [
    {
      "id": "systemA",
      "displayName": "System A",
      "hostName": [{"HOST1": ""}, {"HOST-A": ""}]
    },
    {
      "id": "systemB",

```

```

        "displayName":"System B",
        "hostName":[ {"HOST1":""}, {"HOST-B":""} ]
    }
]
}

```

*Example definition to include the host in System A*

```

{
  "meta":{
    "version":"1"
  },
  "allSystem":[
    {
      "id":"systemA",
      "displayName":"System A",
      "hostName":[ {"HOST1":""}, {"HOST-A":""} ]
    },
    {
      "id":"systemB",
      "displayName":"System B",
      "hostName":[ {"HOST-B":""} ]
    }
  ]
}

```

*Example definition to include the host in System B*

```

{
  "meta":{
    "version":"1"
  },
  "allSystem":[
    {
      "id":"systemA",
      "displayName":"System A",
      "hostName":[ {"HOST-A":""} ]
    },
    {
      "id":"systemB",
      "displayName":"System B",
      "hostName":[ {"HOST1":""}, {"HOST-B":""} ]
    }
  ]
}

```

## ◆ Category name definition file for IM management nodes (imdd\_category\_name.conf)

### Format

```
{
  "meta":{
    "version":"1"
  },
  "categoryData":[
    {"categoryId":"category-ID", "categoryName":"category-name"},
    ...
  ]
}
```

### Files

imdd\_category\_name.conf

imdd\_category\_name.conf.model (model file for the category name definition file for IM management nodes)

### Storage directory

In Windows

For a physical host:

*Manager-path*\conf\imdd\

For a logical host:

*shared-folder*\jplimm\conf\imdd\

In UNIX

For a physical host:

/etc/opt/jplimm/conf/imdd/

For a logical host:

*shared-directory*/jplimm/conf/imdd/

### Description

This file defines the category names and orders of IM management nodes in management groups to display a sunburst or tree chart of data that is collected by the Intelligent Integrated Management Base. The IM management node categories are displayed in the order they are defined.

### When the definitions are applied

The settings in the category name definition file for IM management nodes are applied to the Intelligent Integrated Management Base when the `jddcreatetree` or `jddupdatetree` command is completed successfully.

For details about the `jddcreatetree` and `jddupdatetree` commands, see [jddcreatetree](#) and [jddupdatetree](#) in *Chapter 1. Commands*.

### Information that is specified

The category name definition file for IM management nodes must be saved in UTF-8 without BOM (byte order mark).

"version": "1"

Specifies the version of the category name definition file for IM management nodes. Set this to 1.

"categoryId": "*category-ID*"

The specified default value. Do not edit the value.

"categoryName": "*category-name*"

Specifies a category name of the management group that will appear in a sunburst or tree chart. The value of categoryName can be up to 255 characters in length and must not include any control characters or machine-dependent characters.

## Example definition

*Example of the definition for changing the order of the underlined categories*

*Before the change*

```
{
  "meta": {
    "version": "1"
  },
  "categoryData": [
    {"categoryId": "job", "categoryName": "Job"},
    {"categoryId": "serviceResponse", "categoryName": "Service Response"},
    {"categoryId": "enterprise", "categoryName": "Enterprise"},
    {"categoryId": "transactionProcessing", "categoryName": "Transaction Proces
sing"},
    {"categoryId": "applicationServer", "categoryName": "Application Server"},
    {"categoryId": "database", "categoryName": "Database"},
    {"categoryId": "platform", "categoryName": "Platform"},
    {"categoryId": "virtualMachine", "categoryName": "Virtual Machine"},
    {"categoryId": "managementApplications", "categoryName": "Management Applic
ations"},
    {"categoryId": "otherApplications", "categoryName": "Other Applications"}
  ]
}
```

*After the change*

```
{
  "meta": {
    "version": "1"
  },
  "categoryData": [
    {"categoryId": "job", "categoryName": "Job"},
    {"categoryId": "serviceResponse", "categoryName": "Service Response"},
    {"categoryId": "enterprise", "categoryName": "Enterprise"},
    {"categoryId": "platform", "categoryName": "Platform"},
    {"categoryId": "database", "categoryName": "Database"},
    {"categoryId": "virtualMachine", "categoryName": "Virtual Machine"},
    {"categoryId": "managementApplications", "categoryName": "Management Applic
ations"},
    {"categoryId": "transactionProcessing", "categoryName": "Transaction Proces
sing"},
    {"categoryId": "applicationServer", "categoryName": "Application Server"},
    {"categoryId": "otherApplications", "categoryName": "Other Applications"}
  ]
}
```

```
]
}
```

## ◆ Target host definition file for configuration collection (imdd\_target\_host.conf)

### Format

```
{
  "meta":{
    "version":"1"
  },
  "target":[
    {
      "product":"product-name",
      "hostName":["host-name-1", "host-name-2", ...]
    },
    ...
  ]
}
```

### Files

imdd\_target\_host.conf

imdd\_target\_host.conf.model (model file for the target host definition file for configuration collection)

### Storage directory

In Windows

For a physical host:

*Manager-path*\conf\imdd\

For a logical host:

*shared-folder*\jplimm\conf\imdd\

In UNIX

For a physical host:

/etc/opt/jplimm/conf/imdd/

For a logical host:

*shared-directory*/jplimm/conf/imdd/

### Description

When the Intelligent Integrated Management Base collects configuration data of the monitoring objects of the linked products, the hosts from which to collect data are set for each linked product based on this file.

It is not used to manage JP1/IM - Agent and JP1/Base.

## When the definitions are applied

The settings in the target host definition file for configuration collection are applied to the Intelligent Integrated Management Base when the `jddcreatetree` and `jddupdatetree` commands are completed successfully.

For details about the `jddcreatetree` and `jddupdatetree` commands, see [jddcreatetree](#) and [jddupdatetree](#) in *Chapter 1. Commands*.

## Information that is specified

The target host definition file for configuration collection must be saved in UTF-8 without BOM (byte order mark). If you specify a backslash (\) as part of a character string, immediately before \, specify \ as an escape character.

`"version": "1"`

Specifies the version of the target host definition file for configuration collection. Set this to 1.

`"product": "product-name"`

Specifies an alphanumeric string to represent a product name to be linked. The maximum length is 255 characters. If a target host for configuration collection is specified, this option cannot be omitted.

- AJS3

Specifies that JP1/AJS is linked.

- PFM

Specifies that JP1/PFM is linked.

For products other than the above, set them according to the construction procedure provided by the collaboration source.

`"hostName": ["host-name-1", "host-name-2", . . .]`

Lists the names of hosts from which you want to collect configuration data with a string up to 255 characters.

Acceptable characters are alphanumeric characters and the following symbols: exclamation mark (!), dollar sign (\$), left parenthesis ( ( ), right parenthesis ( ) ), asterisk (\*), plus sign (+), comma ( , ), hyphen ( - ), period ( . ), forward slash ( / ), colon ( : ), left angle bracket ( < ), equal sign ( = ), left square bracket ( [ ), backslash ( \ ), right square bracket ( ] ), caret ( ^ ), left curly bracket ( { ), vertical bar ( | ), and right curly bracket ( } ).

Specify physical host names or logical host names that are registered with the IM configuration. You cannot specify hosts with the same name within linked products. If a target host for configuration collection is specified, this option cannot be omitted.

Register the specified host name to the integrated manager's `hosts` file and DNS so as to enable name resolution on the integrated manager host. Configuration in the `jp1hosts` file and the `jp1hosts2` file are not referred.

## Example definition

*Example to link with JP1/AJS and JP1/PFM*

```
{
  "meta": {
    "version": "1"
  },
  "target": [
    {
      "product": "AJS3",
      "hostName": ["host-01", "host-02", "host-03"]
    },
    {
      "product": "PFM",
```

```

        "hostName": ["host-01", "host-04"]
    }
]
}

```

## ◆ Host name definition file (imdd\_host\_name.conf)

### Format

```

{
  "meta":{
    "version":"1"
  },
  "hostNameDef":[
    {
      "sourceHostName":["host-name-1-in-configuration-information","host-name-2-in-configuration-information"],
      "hostName":"host-name-in-tree",
      "label":"display-name-on-screen"
    },
    ...
  ]
}

```

### Files

imdd\_host\_name.conf

imdd\_host\_name.conf.model (model file for the host name definition file)

### Storage directory

#### In Windows

For a physical host:

*Manager-path*\conf\imdd\

For a logical host:

*shared-folder*\jplimm\conf\imdd\

#### In UNIX

For a physical host:

/etc/opt/jplimm/conf/imdd/

For a logical host:

*shared-directory*/jplimm/conf/imdd/

### Description

A structure of IM management nodes can include products that can have aliases for host names. In such a case, this file is used for mapping between aliases and real host names. If aliases are mapped to their real host name, the real host name is used as a host name in a tree chart. This allows the tree chart to group aliases into the same host even when different management tools use different aliases.

You also use this definition file when you change the host name displayed in the integrated operation viewer.

## When the definitions are applied

The settings in the host name definition file are applied to the Intelligent Integrated Management Base when the `jddcreatetree` and `jddupdatetree` commands are completed successfully.

For details about the `jddcreatetree` and `jddupdatetree` commands, see [jddcreatetree](#) and [jddupdatetree](#) in *Chapter 1. Commands*.

## Information that is specified

The host name definition file must be saved in UTF-8 without BOM (byte order mark). If you specify a backslash (\) as part of a character string, immediately before \, specify \ as an escape character.

`"version": "1"`

Specifies the version of the target host name definition file for configuration collection. Set this to 1.

`"hostNameDef"`

Either `sourceHostName` or `label` must be specified. Specifying `hostName` is required.

`"sourceHostName": [ "host-name-1-in-configuration-information", "host-name-2-in-configuration-information" ]`

List the host names that you want to represent a particular host. You can specify up to 10 host names. Each host name can be up to 255 characters in length.

Acceptable characters are alphanumeric characters and the following symbols: exclamation mark (!), dollar sign (\$), left parenthesis ( ( ), right parenthesis ( ) ), asterisk (\*), plus sign (+), comma ( , ), hyphen (-), period ( . ), forward slash (/), colon ( : ), left angle bracket ( < ), equal sign (=), left square bracket ( [ ), backslash (\), right square bracket ( ] ), caret (^), left curly bracket ( { ), vertical bar ( | ), and right curly bracket ( } ).

`"hostName": "host-name-in-tree"`

Specify a host name in the tree data. The host name can be up to 255 characters in length.

Acceptable characters are alphanumeric characters and the following symbols: exclamation mark (!), dollar sign (\$), left parenthesis ( ( ), right parenthesis ( ) ), asterisk (\*), plus sign (+), comma ( , ), hyphen (-), period ( . ), forward slash (/), colon ( : ), left angle bracket ( < ), equal sign (=), left square bracket ( [ ), backslash (\), right square bracket ( ] ), caret (^), left curly bracket ( { ), vertical bar ( | ), and right curly bracket ( } ).

`"label": "display-name-on-screen"`

Specify a label name to be displayed on the screen. Specify it as a string no more than 255 characters, without any control and machine-dependent characters.

## Host names displayed on the screen

Host names displayed on the screen are determined by the priorities as shown in the table below.

| Priority | Matched with the value of <code>hostName</code> ? | Is <code>label</code> specified? | Is <code>label</code> specified for the value value of the host configuration information SID? | Host name displayed on the screen                                                                       |
|----------|---------------------------------------------------|----------------------------------|------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| High     | Match                                             | Yes                              | --                                                                                             | The value of <code>label</code>                                                                         |
| ↑        | Match                                             | No                               | --                                                                                             | The value of <code>hostName</code>                                                                      |
| ↓        | Unmatch                                           | --                               | Yes                                                                                            | The value of <code>label</code> specified for the value value of the host configuration information SID |

| Priority | Matched with the value of <code>hostName</code> ? | Is label specified? | Is label specified for the value value of the host configuration information SID? | Host name displayed on the screen                                                                   |
|----------|---------------------------------------------------|---------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Low      | Unmatch                                           | --                  | No                                                                                | The host name specified for the configuration information SID (XXXXXX in <code>_HOST_XXXXX</code> ) |

Legend: --: Not applicable

You can see the configuration information SID and its `value` value in the Integrated Operation Viewer window or by using the REST API provided by JP1/IM - Manager. For details about SID, see [7.1 SID](#), and for details about the REST API, see [5. API](#).

## Example definition

*Example 1: Display `hostX` as Host X on the screen*

```
{
  "meta": {
    "version": "1"
  },
  "hostNameDef": [
    {
      "hostName": "hostX",
      "label": "Host X"
    }
  ]
}
```

*Example 2: Display `hostX` as Host X on the screen when hosts defined as alias `hostA` and alias `hostB` are represented as `hostX`*

```
{
  "meta": {
    "version": "1"
  },
  "hostNameDef": [
    {
      "sourceHostName": ["hostA", "hostB"],
      "hostName": "hostX",
      "label": "Host X"
    }
  ]
}
```

## ◆ IM management node link definition file (`imdd_nodeLink_def.conf`)

### Format

```
{
  "meta": {
    "version": "1"
  }
}
```

```

    },
    "links": [
      {

## Files

imdd\_nodeLink\_def.conf

imdd\_nodeLink\_def.conf.model (model file for the IM management node link definition file)

## Storage directory

In Windows

For a physical host:

*Manager-path*\conf\imdd\

For a logical host:

*shared-folder*\jplimm\conf\imdd\

In UNIX

For a physical host:

/etc/opt/jplimm/conf/imdd/

For a logical host:

*shared-directory*/jplimm/conf/imdd/

## Description

This file defines relationships between IM management nodes. You can use this definition file to define new relationships between IM management nodes. If you define the same relationship as that in the IM management node link file (imdd\_nodeLink.json) (which is the one with the same from, to, and type), the relationship defined in this file takes effect in the system.

If JP1/AJS or JP1/PFM is linked, a relationship between monitoring targets is registered automatically by the related node display function. If you want to add other relationships separately and show them in the integrated operation viewer, you can specify them in this definition file. For details about the related node display function, see *3.11 Related node display function* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

If you use the REST API, you can get the settings as data. For details about the REST API, see [5. API](#).

## When the definitions are applied

The settings in the IM management node link definition file are applied to the Intelligent Integrated Management Base when the `jddupdatetree` command is completed successfully.

## Information that is specified

The IM management node link definition file must be saved in UTF-8 without BOM (byte order mark).

`"version": "1"`

Specifies the version of the IM management node link definition file. Set this to 1.

`"from": "configuration-information-SID-or-tree-SID-of-the-preceding-node"`

This node is the preceding node. Specify the configuration information SID or tree SID. For details about characters available for the type and name of SID, see [7.1 SID](#). We recommend that you define the value you referred to in the Integrated Operation Viewer window or with the REST API.

This option is mandatory.

The **Job flow** tab displays relationships between IM management nodes only when `rootJobnetExecutionOrder` is specified for `type` and an SID is specified. If you specify a tree SID, you cannot view relationships between IM management nodes in the window. However, by using the link information acquisition API, you can acquire link information specified with the tree SID. For details, see [5.5.1 Link information acquisition](#).

The **Related node** tab, on the other hand, displays relationships between IM management nodes regardless of the value specified for `type` or whether an SID or tree SID is specified.

Example to specify a root jobnet:

```
_JP1AJS-M_HOST1/_HOST_HOST1/_JP1SCHE_schedulerserv/_JP1JOBG_jobgroup/_JP1R  
OOTJOBNET_jobnet1
```

`"to": "configuration-information-SID-or-tree-SID-of-the-succeeding-node"`

This node is the subsequent node. Specify the configuration information SID or tree SID. For details about characters available for the type and name of SID, see [7.1 SID](#). We recommend that you define the value you referred to in the Integrated Operation Viewer window or with the REST API.

This option is mandatory.

The **Job flow** tab displays relationships between IM management nodes only when `rootJobnetExecutionOrder` is specified for `type` and a SID is specified. If you specify a tree SID, you cannot view relationships between IM management nodes in the window. However, by using the link information acquisition API, you can acquire link information specified with the tree SID. For details, see [7.1 SID](#).

The **Related node** tab, on the other hand, displays relationships between IM management nodes regardless of the value specified for `type` or whether an SID or tree SID is specified.

Example to specify a root jobnet:

```
_JP1AJS-M_HOST1/_HOST_HOST1/_JP1SCHE_schedulerserv/_JP1JOBG_jobgroup/_JP1R  
OOTJOBNET_jobnet2
```

`"type": "information-type"`

Specifies the type indicated by the link information set by `from` and `to`. Control characters are not acceptable. You can specify half-width alphanumeric characters from 1 to 255 bytes. This option is mandatory.

The `type` is the information used to group relationships with the same meaning. In the **Related node** tab of the Integrated Operation Viewer, you can view filtered relationships by `type`.

Use the types listed below within JP1/IM products or for linkage with other products. In addition to these types, you can also specify any type.

- `rootJobnetExecutionOrder` (relationship of execution order of a root jobnet)
- `managerAgent` (relationship between a manager and agent of a JP1 product)
- `rootJobnetAgent` (relationship between a root jobnet and an AJS agent)
- `sameNode` (relationship between nodes having the same name)
- `L2Connection` (relationship between layer-2 connection lines managed by JP1/NNMi)
- `Infrastructure` (relationship of infrastructure resources managed by JP1/OA)
- `monitoringConfiguration` (Relation between a product and a monitoring target in a monitoring product configuration)

If you set `type` to `rootJobnetExecutionOrder`, specify the configuration information SID of the IM management node for `from` and `to`.

`"value"`

Specifies additional link information. This option is optional.

`"unit"`

Specify it if the information type is an execution order of a root jobnet. Specify the information of a linked unit. This option is optional.

`"precedingJob" : "complete-name-of-preceding-linked-unit"`

Specifies the complete name of a preceding linked unit. Specify a string of one megabyte or less other than control characters. This option is mandatory.

Example :

```
/jobnet1/JP1 event sending job
```

`"succeedingJob" : "complete-name-of-subsequent-linked-unit"`

Specifies the complete name of a subsequent linked unit. Specify a string of one megabyte or less other than control characters. This option is mandatory.

Example :

```
/jobnet2/JP1 event reception monitoring job
```

`"succeedingJobTimeType" : "format-of-scheduled-date-and-time-for-linkage"`

Specify it if the information type is an execution order of a root jobnet. Specify a scheduled date and time for linkage. This option is optional. If it is omitted, `endtime` is assumed for operation.

The specified option is ignored when `relationType` is set to `waitCondition`, and `startTime` is used for operation.

- `"startTime"`

Specify it if the link is configured so that execution of the subsequent unit is started after the preceding unit ends. For example, specify it for linkage through cancellation of holding operation.

- `"endTime"`

Specify it if the link is configured so that the wait condition of the subsequent unit is met after the preceding unit ends. For example, use it for the link through event jobs (such as a file monitoring job or incoming email monitoring job).

"relationType": "type-of-linkage"

Specify it when the type of the target is the root jobnet execution order. Specify the type of linkage for precedingJob (full name of the preceding linked unit) and succeedingJob (full name of the subsequent linked unit).

- waitCondition

Specify it for linkage with a wait.

If you specify waitCondition for relationType, then specify the unit whose end is being waited for for precedingJob (complete name of the preceding linked unit), and specify the complete name of the unit with wait conditions for succeedingJob (complete name of the subsequent linked unit).

- jobnetConnector

Specify it for linkage with a jobnet connector.

If you specify jobnetConnector for relationType, then specify the job connector or the full name of the unit of the connection-destination root jobnet for precedingJob (complete name of the preceding linked unit) and succeedingJob (complete name of the subsequent linked unit).

- other

Specify it for other linkages. For linkage with JP1 events, specify this value.

This option can be omitted. If you omit this option, other is assumed for operation.

Note that different dates and times appear in **Scheduled date and time for linkage** of the Linked unit dialog box depending on the specified types of linkage. For details, see the explanation on the linked unit in 2.6.1 *Tabs area* in the *JP1/Integrated Management 3 - Manager GUI Reference*.

## Note

For precedingJob (complete name of the preceding linked unit) and succeedingJob (complete name of the subsequent linked unit), specify the full name of the unit corresponding to the type of linkage that is specified for relationType (type of linkage). If you specify the full name of the unit incorrectly, the correct date and time will not be displayed in **Scheduled date and time for linkage** in the Linked unit dialog box.

## Example definition

```
{
  "meta":{
    "version":"1"
  },
  "links": [
    {
      "from":_JP1AJS-M_HOST1/_HOST_HOST1/_JP1SCHE_schedulerserv
/_JP1JOBG_jobgroup/_JP1ROOTJOBNET_jobnet1",
      "to":_JP1AJS-M_HOST1/_HOST_HOST1/_JP1SCHE_schedulerserv
/_JP1JOBG_jobgroup/_JP1ROOTJOBNET_jobnet2",
      "type":"rootJobnetExecutionOrder",
      "value":{

          {
            "precedingJob":"/jobnet1/job1",
            "succeedingJob":"/jobnet2/Job2",
            "succeedingJobTimeType":"startTime"
            "relationType":"other"
          }, ...
        ]
      }
    }
  ]
}
```

```

    }, ...
  ],
}

```

## ◆ Suggestion definition file (imdd\_suggestion.conf)

### Format of the whole suggestion definition file

```

{
  "meta":{
    "version":"1"
  },
  "suggestions":[
    {
      "suggestionId":"suggestion-ID",
      "label":"label-name-of-the-suggestion",
      "node":"node-on-which-suggestion-information-is-shown",
      "permissions":[
        ["JP1-permission-for-showing-suggestion-information",...],
        ["JP1-permission-for-showing-suggestion-information",...],
        ...
      ],
      "cases":[
        [
          "suggestion-activation-criteria",
          "suggestion-activation-criteria",
          ...
        ],
        [
          "suggestion-activation-criteria",
          "suggestion-activation-criteria",
          ...
        ],
        ...
      ],
      "action":{
        "response-action-information"
      }
    },
    ...
  ]
}

```

### Files

imdd\_suggestion\_*any-file-name*.conf (user-created suggestion definition file)

imdd\_suggestion.conf (suggestion definition file)

imdd\_suggestion.conf.model (model file for the suggestion definition file)

## Storage directory

### In Windows

For a physical host:

*Manager-path*\conf\imdd\suggestion

For a logical host:

*shared-folder*\jplimm\conf\imdd\suggestion

### In UNIX

For a physical host:

/etc/opt/jplimm/conf/imdd/suggestion

For a logical host:

*shared-directory*/jplimm/conf/imdd/suggestion

For user-created suggestion definition files, copy the `imdd_suggestion.conf` file and store it in a given directory, and use the argument of the `jddupdatesuggestion` command to specify a directory path.

## Description

A suggestion definition file defines criteria for suggesting response actions (suggestion display criteria and suggestion activation criteria) and what the actions do.

You can create more than one suggestion definition file. You can also create multiple suggestion definitions in one suggestion definition file. You should specify a suggestion ID (`suggestionId`) for each suggestion definition, so that it will be identified as an individual suggestion definition. Therefore, unique suggestion IDs must be specified in all suggestion definition files. If a specified suggestion ID is duplicated, an error occurs when the suggestion definition files are applied.

## When the definitions are applied

When the `jddupdatesuggestion` command is completed successfully, the information in the suggestion definition file takes effect in the Intelligent Integrated Management Base.

## Information that is specified

Save the suggestion definition file in UTF-8 format, with no byte order mark (BOM) added to it. The following shows the information that is specified in the whole suggestion definition file.

"meta"

Specifies meta information. The data type is object. This member cannot be omitted.

"version": "1"

Is the version of the suggestion definition file. Specify 1. The data type is string. This member cannot be omitted.

"suggestions"

Is an array of suggestion definition objects. You can specify 0 to 1,000 definitions in a suggestion definition file (the total number of definitions for all suggestion definition files is 1,000). The data type is object[]. This member cannot be omitted.

"suggestionId": "*suggestion-ID*"

Specifies a unique suggestion ID throughout all suggestion definition files.

The suggestion ID can consist of half-width alphanumeric characters, hyphens (-), and underscores (\_). You can specify from 1 to 255 characters.

Use an easy-to-understand suggestion ID because it is specified in a request for the REST API or used for message padding.

Note that in the suggestion list area on the **Suggestion** tab of the Integrated Operation Viewer window, the suggestions are sorted in order of activation status and character code of the suggestion ID. Therefore, define a suggestion ID with characters that come earlier in the character code order for a suggestion definition with higher priority.

Any string starting with JP1, jpl, hitachi, or HITACHI is not available for the suggestion ID.

The data type is string. This member cannot be omitted.

"label": "*label-name-of-the-suggestion*"

on the **Suggestion** tab of the Integrated Operation Viewer window and as **Suggestion name** in the **Suggestion details** area. You specify it as a string from 1 to 60 characters without any control characters. The data type is string. This member cannot be omitted.

"node": "*IM-management-node-on-which-suggestion-information-is-shown*"

Specifies the tree SID of the IM management node on which the suggestion is shown, with the regular expression. It can consist of half-width alphanumeric characters and symbols.

The suggestion information can be shown only on the IM management node with the tree SID that partially matches the specified regular expression. The data type is string. This member cannot be omitted.

"permissions": [ [ "*JP1-user-permission-under-which-the-suggestion-information-is-shown*" ] ]

Specifies the JP1 user permission under which the suggestion information is shown in double arrays.

A set of conditions specified in interior square brackets ( [ ] ) is evaluated as an AND condition, whereas one specified in exterior square brackets is evaluated as an OR condition. You can specify 1 to 100 JP1 permissions as a combination of interior and exterior square brackets. The data type is string[[]].

This member can be omitted. If it is omitted, the system follows the view condition for IM management nodes in the Integrated Operation Viewer window.

"cases": [ [ "*suggestion-activation-criteria*" ] ]

Specifies information on suggestion activation criteria in double arrays.

A set of conditions specified in interior square brackets ( [ ] ) is evaluated as an AND condition, whereas one specified in exterior square brackets is evaluated as an OR condition. You can specify 1 to 100 sets of suggestion activation criteria as a combination of interior and exterior square brackets. The data type is object[[]].

This member can be omitted. If it is omitted, the system assumes that the condition is always true.

"action": "*response-action-information*"

Specifies information on a response action. The data type is object. This member cannot be omitted.

You can use variables in the definition of suggestion activation criteria and response actions. For details about the use of variables, see (3) *Variables*.

## (1) Suggestion activation criteria

Specify criteria when the suggestion function suggests response actions as suggestion activation criteria. Each criterion you specify has a *criterion key*, *comparison keyword*, and *value to be compared with*. Whether a criterion is true is determined by evaluating the target specified as the *criterion key* and the value specified as the *value to be compared with* using the comparison methods specified as the *comparison keyword*.

The suggestion activation criteria should be specified as an element of the `cases` parameter in the suggestion definition file. An interior array within the double array uses an AND condition, whereas an exterior array uses an OR condition. One AND-condition array is called a *suggestion activation criteria group*. The following shows an example of the suggestion activation criteria group:

```
cases:[
  [suggestion-activation-criterion-1,suggestion-activation-criterion-2]
,   <- Suggestion activation criteria group a
  [suggestion-activation-criterion-3,suggestion-activation-criterion-4]
]   <- Suggestion activation criteria group b
]
```

In the above examples, suggestion activation criteria 1 and 2 are evaluated as an AND condition, whereas the suggestion activation criteria groups a and b are evaluated as an OR condition.

The suggestion activation criteria are evaluated in the order specified in the `cases` members. In the above example, the criteria are evaluated in the order of suggestion activation criterion 1, suggestion activation criterion 2, suggestion activation criterion 3, and suggestion activation criterion 4.

However, the evaluation can be skipped if a suggestion activation criteria group is not met or the suggestion activation criteria in the applicable suggestion definition are met.

For example, if a failed suggestion activation criterion is found in a suggestion activation criteria group, the evaluation is skipped even when some suggestion activation criteria have not been evaluated yet, because the suggestion activation criteria group is not met as an AND condition. If a suggestion activation criteria group is met, the evaluation is skipped even when some suggestion activation criteria groups have not been evaluated yet because the suggestion activation criteria in the applicable suggestion definition are met as an OR condition.

The following shows an example in which the evaluation of some suggestion activation criteria is skipped:

```
cases:[
  [suggestion-activation-criterion-1 (false), suggestion-activation-criter
ion-2 (skipped)],   <- Suggestion activation criteria group a
  [suggestion-activation-criterion-3 (true), suggestion-activation-criteri
on-4 (true)],       <- Suggestion activation criteria group b
  [suggestion-activation-criterion-5 (skipped), suggestion-activation-crit
erion-6 (skipped)]  <- Suggestion activation criteria group c
]
```

In the above example, when suggestion activation criterion 1 is determined to be false, suggestion activation criteria group a is not met and the evaluation of suggestion activation criterion 2 is skipped. When suggestion activation criteria 3 and 4 are determined to be true, suggestion activation criteria group b is met. This results in the suggestion activation criteria in the applicable suggestion definition being met, causing the evaluation of suggestion activation criteria 5 and 6 to be skipped.

Furthermore, if a suggestion activation criterion is determined to be an error due to a failure to get criterion information or to convert a variable, the suggestion activation criteria in the applicable suggestion definition are determined to be an error, causing all the subsequent evaluations to be skipped.

The following shows an example where all evaluations are skipped:

```
cases:[
  [<suggestion-activation-criterion-1(true)>, <suggestion-activation-crite
rion-2(error)>],
  [<suggestion-activation-criterion-3(skipped)>, <suggestion-activation-cr
iterion-4(skipped)>],
  [<suggestion-activation-criterion-5(skipped)>, <suggestion-activation-cr
iterion-6(skipped)>]
]
```

If suggestion activation criterion 2 is determined to be an error, then the suggestion activation criteria in the applicable suggestion definition are determined to be an error, causing the evaluations of suggestion activation criteria 3 to 6 to be skipped.

The cases members in interior [ ] are evaluated as an AND condition and those in exterior [ ] as an OR condition, and thus a set of OR conditions cannot be connected as an AND condition. To specify the same condition, you can rewrite the condition as follows:

(Before rewriting)

```
(condition A OR condition B) AND (condition C OR condition D)
```

(After rewriting)

```
(condition A AND condition C) OR (condition A AND condition D) OR (condition B AND condition C) OR (condition B AND condition D)
```

Although you have to specify the same condition twice, it takes no time to evaluate it because the second evaluation uses the criterion information for evaluating the suggestion activation criterion obtained from JP1/IM or linked products at the time of the first evaluation.

If you want to connect AND and OR conditions in a complicated manner, you can also use plug-in functions or batch shell scripts to evaluate the conditions in these programs, in addition to the above method.

#### Note

If you want to check the criterion information acquired when judging the respective suggestion activation criteria (such as the standard output for a command or the REST API status code) when a suggestion is established, specify the variable of the suggestion activation criteria execution result in the `description` member of the response action. For details about variables, see [\(3\) Variable](#).

## Format of suggestion activation criterion

```
{
  "type": "type-of-criterion",
  "key": "criterion-key",
  "ope": "comparison-keyword",
  "val": "value-to-be-compared-with",
  "cache": "availability-of-criterion-information-cache",
  "description": "description-of-the-criterion"
}
```

## Information that is specified in a suggestion activation criterion

`"type": "type-of-criterion"`

Specifies the type of the suggestion activation criterion. For details about possible values, see the table below. The data type is string. This member cannot be omitted.

Table 2–10: Members available for type

| No. | Value | Description                                             |
|-----|-------|---------------------------------------------------------|
| 1   | event | Specify it when you define a criterion for a JP1 event. |

| No. | Value      | Description                                                                                                                                                                                                  |
|-----|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | eventCount | Specify it when you define a criterion for the number of JP1 events.                                                                                                                                         |
| 3   | trendCount | Specify it when you define a criterion for the number of time-series data sets.                                                                                                                              |
| 4   | restApi    | Specify it when you define an execution result of the REST API.                                                                                                                                              |
| 5   | plugin     | Specify it when you define a criterion for an execution result of a product plug-in.                                                                                                                         |
| 6   | cmd#       | Specify it when you define a criterion for an execution result of a command. For details about commands you can execute, the execution host, and the login user, see <a href="#">4.5.10 jp1lmd.execCmd</a> . |
| 7   | struct     | Specify it when you define a criterion for IM management nodes.                                                                                                                                              |

#

You can specify this value when JP1/Base on the execution host for the command is version 12-10 or later. If the version is earlier than 12-10, the command execution fails, and the return value of 0 as well as empty standard output and standard error output are returned.

"key": "*criterion-key*"

Specifies the target of the suggestion activation criterion. Possible values vary depending on the value specified for the `type` member. The data type is object. This member cannot be omitted.

"ope": "*comparison-keyword*"

Specifies a keyword for comparison. Possible values vary depending on the value specified for the `type` member. The data type is string. This member cannot be omitted.

"val": "*value-to-be-compared-with*"

Specifies the value to be compared with. Possible values vary depending on the value specified for the `type` member. The data type depends on the `ope` member. This member cannot be omitted.

"cache": "*availability-of-criterion-information-cache*"

Specifies whether the cache of criterion information is used to evaluate the suggestion activation criterion.

- When the cache is used

If a suggestion activation criterion is evaluated with the suggestion activation criterion having the same `key` before the cache expires, the information in the cache is used without getting the criterion information. The cache expires in 10 minutes.

- When the cache is not used

Criterion information is always obtained to evaluate a suggestion activation criterion.

Specify either `true` or `false`. Specify `true` if you use the cache, or `false` if not.

This member is not available if the `type` member is set to `struct`. It is ignored if specified. When you specify `true`, the cache is created and updated when criterion information is obtained using the response action suggestion API.

The data type is Boolean. This member can be omitted. If it is omitted, the system assumes `false` for operation.

"description": "*description-of-the-criterion*"

Specifies the description of the suggestion activation criterion that is displayed in the **Suggestion details** area on the **Suggestion** tab of the Integrated Operation Viewer window, as a string from 1 to 512 characters without any control characters. The data type is string. This member cannot be omitted.

## (A) Possible values for each of the `key`, `ope`, and `val` members

Different values can be specified for each of the `key`, `ope`, and `val` members depending on `type` (type of criterion) of a suggestion activation criterion. The possible values for each member are described here. Note that the `cache` and `description` members can be specified regardless of what `type` is.

### (a) Suggestion activation criterion when type is set to event

When type (type of criterion) is set to event, whether any JP1 event that meets particular conditions exists can be specified as a suggestion activation criterion.

#### Format

```
{
  "type": "event",
  "key": {
    "sid": "tree-SID-of-the-node-with-which-the-event-is-associated",
    "statusFilter": status-of-node,
    "attribute-name": "attribute-value",
    "REGEX_attribute-name": "attribute-value"
  },
  "ope": "comparison-keyword",
  "val": "value-to-be-compared-with",
  "cache": "availability-of-criterion-information-cache",
  "description": "description-of-the-criterion"
}
```

#### Information that is specified

##### "key"

This is an object that specifies the information on JP1 events which are subject to the suggestion activation criterion. The data type is object. This member cannot be omitted.

##### "sid": "tree-SID-of-the-node-with-which-the-event-is-associated"

Specifies the tree SID of the node with which the event is associated. Possible characters conform to the specifications of the tree SID. The data type is string. This member can be omitted. If it is omitted, the system assumes that the selected node is specified.

##### "statusFilter": status-of-node

Specifies the statuses of nodes as an array if you narrow down to only events that have applicable node statuses. Possible values are as follows:

- 10: Green  
It narrows down events to processed events, released or deleted severe events, and events other than severe events.
- 20: Yellow  
It narrows down events to severe events with the severity of Warning, Debug, and Information and the event status of Unprocessed, Processing, and Held.
- 30: Orange  
It narrows down events to severe events with the severity of Error and the event status of Unprocessed, Processing, and Held.
- 40: Red  
It narrows down events to severe events with the severity of Emergency, Alert, and Critical and the event status of Unprocessed, Processing, and Held.

When multiple values are specified, events are searched for in the OR condition.

When the severe events filter function or the severe event release and delete function is used to change events that correspond to the severe event, the events are narrowed down according to the status after the change when suggestion activation criteria are evaluated.

The data type is `number[]`. This member can be omitted. However, we recommend that you specify it in order to improve the performance of the event search.

`"attribute-name" : "attribute-value"`

Specifies the value of the attribute specified by the attribute name for the event. The attribute names available as a member are the same as those values that can be specified for `key` in the event search condition object. The values that can be specified for each attribute name are the same as those values that can be specified for `val` in the search condition object. A single value can contain up to 4,096 bytes, and a single suggestion activation criterion can contain up to 4,096 bytes (total size of values specified for `<attribute-name>` and `<REG_attribute-name>` of a single suggestion activation criterion). For details about criterion information objects, see [7.2.1 \(3\) Event search condition object](#). However, if a half-width space is specified in the value of each attribute, the system assumes that `%20` is specified.

An event that exactly matches the value is searched for. If the value is an array, an event that exactly matches one of the values is searched for.

If neither the attribute name `B.TIME` (registered time) nor the attribute name `B.ARRIVEDTIME` (arrived time) is specified, the system assumes that the following value is specified as a value of the attribute name `B.TIME`:

```
[ "one-day-before-the-current-time", "current-time" ]
```

If the attribute name `E.START_TIME` (start time) and the attribute name `E.END_TIME` (end time) have one of the following values, the system assumes no match, no matter what dates and times are specified:

- Value that is not a number
- Number less than 0
- Number of 4,102,444,800 or more

The data type depends on *attribute-name*. This member can be omitted.

`"REGEX_attribute-name" : "attribute-value"`

Specifies the value of the attribute specified by *attribute-name* for the event. The attribute names available as a member are those values that can be specified for `key` of the event search condition object, which are attribute names for attributes containing a regular expression for the comparison keyword that can be specified. The values that can be specified for each attribute name are the same as those values that can be specified for `val` in the search condition object. A single value can contain up to 4,096 bytes, and a single suggestion activation criterion can contain up to 4,096 bytes (total size of values specified for `<attribute-name>` and `<REG_attribute-name>` of a single suggestion activation criterion). For details about criterion information objects, see [7.2.1 \(3\) Event search condition object](#). However, if a half-width space is specified in the value of each attribute, the system assumes that `%20` is specified.

Events that partly match the value of the specified regular expression are searched for.

The data type is string. This member can be omitted.

`"ope" : "comparison-keyword"`

Specifies a keyword for comparison. A possible value is as follows:

- `EXIST`: Whether JP1 events that meet all the conditions specified in `key` exist

The data type is string. This member cannot be omitted.

`"val" : "value-to-be-compared-with"`

Specifies whether JP1 events that meet all the conditions specified in `key` exist.

Specify either `true` or `false`. Specify `true` if JP1 events exist, or `false` if they do not.

The data type is Boolean. This member cannot be omitted.

For details about the cache and description members, see the description for each member in *(1) Suggestion activation criteria*.

..

### Example

Here is an example of evaluating whether JP1 events that meet the following conditions are issued:

- They are associated with the selected IM management node.
- Events that have the status of *Yellow* (Warning) or higher.
- The registration dates of the events are within the past 60 minutes.
- Their event ID is 00004860, which is the one for the JP1/PFM health check event.
- The message of the event contains the health check status indicating that the host has stopped.
- The event status of the event is Unprocessed. (Its status is not Processing or Held.)

```
{
  "type": "event",
  "key": {
    "statusFilter": [20, 30, 40],
    "B.TIME": ["${:time:-60.m.}", "${:time:}"],
    "B.ID": ["00004860"],
    "REGEX_B.MESSAGE": "KAVL15022-E.*hcsstatus=Host Not Available",
    "E.@JP1IM_DEALT": [0]
  },
  "ope": "EXIST",
  "val": true,
  "description": "A JP1 event indicating that the host stopped has been issued"
}
```

### (b) Suggestion activation criterion when type is set to eventCount

When type (type of criterion) is set to eventCount, the number of JP1 events that meet particular conditions can be specified as a suggestion activation criterion.

#### Format

```
{
  "type": "eventCount",
  "key": {
    "sid": "tree-SID-of-the-node-with-which-the-event-is-associated",
    "statusFilter": status-of-node,
    "attribute-name": "attribute-value",
    "REGEX_attribute-name": "attribute-value"
  },
  "ope": "comparison-keyword",
  "val": value-to-be-compared-with,
  "cache": "availability-of-criterion-information-cache",
  "description": "description-of-the-criterion"
}
```

### Information that is specified

"key"

This is an object that specifies the information on JP1 events which are subject to the suggestion activation criterion. The data type is object. This member cannot be omitted.

"sid" : *"tree-SID-of-the-node-with-which-the-event-is-associated"*

This is an object that specifies the information on JP1 events which are subject to the suggestion activation criterion. The data type is string. This member can be omitted. If it is omitted, the system assumes that the selected node is specified.

"statusFilter" : *status-of-node*

Specifies the statuses of nodes as an array if you narrow down to only events that have applicable node statuses. Possible values are as follows:

- 10: Green  
It narrows down events to processed events, released or deleted severe events, and events other than severe events.
- 20: Yellow  
It narrows down events to severe events with the severity of Warning, Debug, and Information and the event status of Unprocessed, Processing, and Held.
- 30: Orange  
It narrows down events to severe events with the severity of Error and the event status of Unprocessed, Processing, and Held.
- 40: Red  
It narrows down events to severe events with the severity of Emergency, Alert, and Critical and the event status of Unprocessed, Processing, and Held.

When multiple values are specified, events are searched for in the OR condition.

When the severe events filter function or the severe event release and delete function is used to change events that correspond to the severe event, the events are narrowed down according to the status after the change when suggestion activation criteria are evaluated.

The data type is number[]. This member can be omitted. However, we recommend that you specify it in order to improve the performance of the event search.

"attribute-name" : *"attribute-value"*

Specifies the value of the attribute specified by the attribute name for the event. The attribute names available as a member are the same as those values that can be specified for `key` in the event search condition object. The values that can be specified for each attribute name are the same as those values that can be specified for `val` in the search condition object. A single value can contain up to 4,096 bytes, and a single suggestion activation criterion can contain up to 4,096 bytes (total size of values specified for `<attribute-name>` and `<REG_<attribute-name>` of a single suggestion activation criterion). For details about criterion information objects, see [7.2.1 \(3\) Event search condition object](#). However, if a half-width space is specified in the value of each attribute, the system assumes that `%20` is specified.

An event that exactly matches the value is searched for. If the value is an array, an event that exactly matches one of the values is searched for.

If neither the attribute name `B.TIME` (registered time) nor the attribute name `B.ARRIVEDTIME` (arrived time) is specified, the system assumes that the following value is specified as a value of the attribute name `B.TIME`:

```
[ "one-day-before-the-current-time", "current-time" ]
```

If the attribute name `E.START_TIME` (start time) and the attribute name `E.END_TIME` (end time) have one of the following values, the system assumes no match, no matter what dates and times are specified:

- Value that is not a number
- Number less than 0
- Number of 4,102,444,800 or more

The data type depends on *attribute-name*. This member can be omitted.

"REGEX\_*attribute-name*" : "*attribute-value*"

Specifies the value of the attribute specified by *attribute-name* for the event. The attribute names available as a member are those values that can be specified for key of the event search condition object, which are attribute names for attributes containing a regular expression for the comparison keyword that can be specified. The values that can be specified for each attribute name are the same as those values that can be specified for *val* in the search condition object. A single value can contain up to 4,096 bytes, and a single suggestion activation criterion can contain up to 4,096 bytes (total size of values specified for <*attribute-name*> and <REG\_*attribute-name*> of a single suggestion activation criterion). For details about criterion information objects, see [7.2.1 \(3\) Event search condition object](#). However, if a half-width space is specified in the value of each attribute, the system assumes that %20 is specified.

Events that partly match the value of the specified regular expression are searched for.

The data type is string. This member can be omitted.

"ope" : "*comparison-keyword*"

Specifies a keyword for comparison. Possible values are as follows:

- GT: The number of JP1 events that meet the conditions specified in *key* is greater than the value specified in *val*.
- LT: The number of JP1 events that meet the conditions specified in *key* is less than the value specified in *val*.

The data type is string. This member cannot be omitted.

"val" : *value-to-be-compared-with*

Specifies the number of JP1 events that meet the conditions specified in *key*, as an integer from 0 to 100.

The data type is number. This member cannot be omitted.

For details about the *cache* and *description* members, see the description for each member in [\(1\) Suggestion activation criteria](#).

## Example

Here is an example of evaluating whether more than 10 JP1 events that meet the following conditions are issued:

- They are associated with the selected IM management node.
- Events that have the status of *Yellow* (Warning) or higher.
- The registration dates of the events are within the past 60 minutes.
- Their event ID is 00004860, which is the one for the JP1/PFM health check event.
- The message of the event contains the health check status indicating that the host has stopped.
- The event status of the event is Unprocessed. (Its status is not Processing or Held.)

```
{
  "type": "eventCount",
  "key": {
    "B.TIME": [ "${:time:-60.m.:}", "${:time:}" ],
    "B.ID": [ "00004860" ],
    "REGEX_B.MESSAGE": "KAVL15022-E.*hcsstatus=Host Not Available",
    "E.@JP1IM_DEALT": [ 0 ]
  },
  "ope": "GT",
```

```

    "val":10,
    "description":"More than 10 JP1 events indicating that the host has stopped have been issued within the past one hour"
  }

```

### (c) Suggestion activation criterion when type is set to trendCount

When type (type of criterion) is set to `trendCount`, the number of time-series data sets that meet particular conditions can be specified as a suggestion activation criterion.

#### Format

```

{
  "type":"trendCount",
  "key":{
    "sid":"tree-SID",
    "metric":"metric-name",
    "startTime":"start-date-and-time",
    "endTime":"end-date-and-time",
    "countPerInstance":upper-limit-for-the-number-of-data-sets-per-instance,
    "instanceCount":upper-limit-for-the-number-of-instances,
    "instance":"instance-name",
    "threshold":threshold-value,
    "thresholdType":"threshold-value-type"
  },
  "ope":"comparison-keyword",
  "val":value-to-be-compared-with,
  "cache":"availability-of-criterion-information-cache",
  "description":"description-of-the-criterion"
}

```

#### Information that is specified

##### "key"

This is an object that specifies the information on time-series data which is subject to the suggestion activation criterion.

The data type is object. This member cannot be omitted.

##### "sid": "tree-SID"

Specifies the tree SID of time-series data. Possible characters conform to the specifications of the tree SID.

If multiple configuration information SIDs are associated with the specified tree SID, the time-series data from one configuration information SID is obtained.

If the time-series data is obtained successfully, it is used to evaluate the conditions. If obtaining it fails, the next time-series data is obtained.

When time-series data is unable to be obtained for all configuration information SIDs, obtaining criterion information is a failure. The order of obtaining time-series data is undefined.

The data type is string. This member can be omitted. If it is omitted, the system assumes that the selected node is specified.

##### "metric": "metric-for-time-series-data"

Specifies a metric for time-series data. You specify it with half-width alphanumeric characters, hyphens (-), and underscores (\_) of 255 characters or fewer. The data type is string. This member cannot be omitted.

"startTime": *"start-date-and-time-of-the-time-series-data"*

Specifies the start date and time of time series data as the UTC time in ISO 8601 format. Do not specify the seconds after the decimal point. The data type is string. This member cannot be omitted.

"endTime": *"end-date-and-time-of-the-time-series-data"*

Specifies the end date and time of time-series data as the UTC time in ISO 8601 format. Do not specify the seconds after the decimal point. The data type is string. This member cannot be omitted.

"countPerInstance": *upper-limit-for-the-number-of-data-sets-per-instance*

Specifies the upper limit for the number of data sets per instance to be obtained. An integer from 1 to 30,000 can be specified. Specify it so that the number obtained by multiplying `countPerInstance` by `instanceCount` is 30,000 or less. The data type is number. This member can be omitted. If it is omitted, the system assumes 60 for operation.

"instanceCount": *upper-limit-for-the-number-of-instances*

Specifies the upper limit for the number of instances. An integer from 1 to 30,000 can be specified. Specify it so that the number obtained by multiplying `countPerInstance` by `instanceCount` is 30,000 or less. The data type is number. This member can be omitted. If it is omitted, the system assumes 10 for operation.

"instance": *"instance-name"*

Specifies the instance name of the instance that is subject to the suggestion activation criterion when there are multiple instances in the time-series data. The data type is string. This member can be omitted. If it is omitted, the first instance is subject to the suggestion activation criterion.

A string of up to 255 characters without any control character can be specified.

"threshold": *threshold-value*

Specifies the threshold value for the target time-series data. The data type is number. This member cannot be omitted.

"thresholdType": *"threshold-value-type"*

Specifies the range of the target time-series data. Possible values are as follows:

- <: The range of targets is less than the value specified for `threshold`.
- <=: The range of targets is less than or equal to the value specified for `threshold`.
- >: The range of targets is more than the value specified for `threshold`.
- >=: The range of targets is more than or equal to the value specified for `threshold`.

The data type is string. This member cannot be omitted.

"ope": *"comparison-keyword"*

Specifies a keyword for comparison. Possible values are as follows:

- GT: The number of time-series data sets that meet the conditions specified in `key` is greater than the value specified in `val`.
- LT: The number of time-series data sets that meet the conditions specified in `key` is less than the value specified in `val`.

The data type is string. This member cannot be omitted.

"val": *value-to-be-compared-with*

Specifies the number of time-series data sets that meet the conditions specified in `key`. An integer from 0 to 30,000 can be specified. The data type is number. This member cannot be omitted.

For details about the `cache` and `description` members, see the description for each member in [\(1\) Suggestion activation criteria](#).

## Example

Here is an example of evaluating whether one or more time-series data sets that meet the following conditions exist:

- Target node: Selected node
- Metric: CPU usage
- Start date and time: One hour ago
- End date and time: Current time
- Upper limit for the number of data sets per instance: 60
- Upper limit for the number of instances: 10
- Threshold value: 80
- Threshold value type: Greater than the threshold value

```
{
  "type": "trendCount",
  "key": {
    "sid": "${.tree:sid:}",
    "metric": "cpu_used_rate",
    "startTime": "${:time:-60.m.:}",
    "endTime": "${:time:}",
    "countPerInstance": 60,
    "instanceCount": 10,
    "threshold": 80,
    "thresholdType": ">"
  },
  "ope": "GT",
  "val": 0,
  "description": "One or more time-series data sets that exceeded 80% are found in the time-series data of CPU usage for the past one hour"
}
```

### (d) Suggestion activation criterion when type is set to restApi

When type (type of criterion) is set to restApi, the execution result of the REST API (the status code, response header, and response body) can be specified as a suggestion activation criterion.

## Format

```
{
  "type": "restApi",
  "key": {
    "method": "method-of-the-REST-API",
    "url": "URL-of-the-REST-API",
    "headers": "request-header-of-the-REST-API",
    "body": "request-body-of-the-REST-API",
    "param": "parameter-to-be-compared-with-in-the-response-of-the-REST-API"
  },
  "ope": "comparison-keyword",
  "val": "value-to-be-compared-with",
  "cache": "availability-of-criterion-information-cache",
  "description": "description-of-the-criterion"
}
```

## Information that is specified

"key"

This is an object that specifies the information on the REST API which is subject to the suggestion activation criterion.

The data type is object. This member cannot be omitted.

"method": "*method-of-the-REST-API*"

Specifies a method of the REST API. Possible values are as follows:

- GET
- HEAD
- POST
- PUT
- PATCH
- DELETE
- OPTIONS
- TRACE

The data type is string. This member cannot be omitted.

"url": "*URL-of-the-REST-API*"

Specifies the URL of the REST API. Possible characters are half-width alphanumeric characters and the following symbols that conform to the RFC 2396 specifications:

;, /, ?, :, @, &, =, +, \$, %, -, \_, ., !, ~, \*, ', (, ), %

Begin the URL with `http://` or `https://`.

The data type is string. This member cannot be omitted.

When the URL including host name is specified, register the host name to the integrated manager's `hosts` file and DNS so as to enable name resolution on the integrated manager host. Configuration in the `jplhosts` file and the `jplhosts2` file are not referred.

"headers": "*request-header-of-the-REST-API*"

Specifies the request header of the REST API. The data type is object. This member cannot be omitted.

"body": "*request-body-of-the-REST-API*"

Specifies the request body of the REST API. The data type is object. When the GET or DELETE method is used and the body is not required, omit this member. This member can be omitted.

"param": "*parameter-to-be-compared-with-in-the-response-of-the-REST-API*"

Specifies the parameter to be compared with in the response of the REST API. Possible values are as follows:

- status: Status code
- headers: Response header
- body: Response body

The data type is string. This member cannot be omitted.

"ope": "*comparison-keyword*"

Specifies a keyword for comparison. Possible values are as follows:

- IN: The response of the REST API specified in `key` matches the value specified for `val`.
- NOTIN: The response of the REST API specified in `key` does not match the value specified for `val`.
- GT: The response of the REST API specified in `key` is greater than the value specified for `val`.

- LT: The response of the REST API specified in `key` is less than the value specified for `val`.
- REGEX: The response of the REST API specified in `key` partly matches the value specified for `val` by a regular expression.

The data type is string. This member cannot be omitted.

"val": "value-to-be-compared-with"

Specifies the value to be compared with the execution result of the REST API. Possible values vary depending on the value of `param`. For details, see the table below. If the type is string, specify a string of less than 1 megabyte in size. This member cannot be omitted.

Table 2–11: Combinations of `param`, `ope`, and the type of `val` available for `restApi`

| No. | param value | Value available for ope                                                                             | Type of val | Value to be specified for val                                 |
|-----|-------------|-----------------------------------------------------------------------------------------------------|-------------|---------------------------------------------------------------|
| 1   | status      | <ul style="list-style-type: none"> <li>• IN</li> <li>• NOTIN</li> <li>• GT</li> <li>• LT</li> </ul> | number      | Value to be compared with the status code of the REST API     |
| 2   | headers     | <ul style="list-style-type: none"> <li>• IN</li> <li>• NOTIN</li> <li>• REGEX</li> </ul>            | string      | Value to be compared with the response header of the REST API |
| 3   | body        | <ul style="list-style-type: none"> <li>• IN</li> <li>• NOTIN</li> <li>• REGEX</li> </ul>            | string      | Value to be compared with the response body of the REST API   |

### Format of the string for the REST API response header

When `param` is set to `headers`, the response header obtained will be a string in the following format:

```
<field-name-1>:<field-value-1-1>,<field-value-1-2>,...,<field-value-1-n><CRLF>
<field-name-2>:<field-value-2-1>,<field-value-2-2>,...,<field-value-2-n><CRLF>
<field-name-3>:<field-value-3-1>,<field-value-3-2>,...,<field-value-3-n><CRLF>
...
```

Note: All the field names are converted into uppercase characters. The fields are arranged in ascending order of the field names in ASCII code.

The following shows an example of how they are specified:

```
CACHE-CONTROL:no-store,no-cache,max-age=0<CRLF>
CONTENT-TYPE:application/json<CRLF>
EXPIRES:Thu,01 Jan 1970 00:00:00 GMT<CRLF>
PRAGMA:no-cache<CRLF>
```

For details about the `cache` and `description` members, see the description for each member in [\(1\) Suggestion activation criteria](#).

### Example

Here is an example of evaluating whether the status code of the following REST API is 200:

- Method: POST
- URL: `https://test`

- Request header  
Authentication information: yyyy/zzzz  
Media type of the request body: application/json
- Request body  
Request body parameter body1: test1  
Request body parameter body2: test2
- Parameter to be compared with in the REST API response: Status code

```
{
  "type": "restApi",
  "key": {
    "method": "POST",
    "url": "https://test",
    "headers": {
      "Authorization": "yyyy/zzzz",
      "Content-Type": "application/json"
    },
    "body": {
      "body1": "test1",
      "body2": "test2"
    },
    "param": "status"
  },
  "ope": "IN",
  "val": 200,
  "description": "The status code of REST API test is 200"
}
```

### (e) Suggestion activation criterion when type is set to plugin

When type (type of criterion) is set to plugin, the execution result of the plug-in function can be specified as a suggestion activation criterion.

#### Format

```
{
  "type": "plugin",
  "key": {
    "sid": "tree-SID",
    "method": "name-of-the-plug-in-function",
    "args": "arguments-of-the-plug-in-function"
  },
  "ope": "comparison-keyword",
  "val": "value-to-be-compared-with",
  "cache": "availability-of-criterion-information-cache",
  "description": "description-of-the-criterion"
}
```

### Information that is specified

#### "key"

This is an object that specifies the information on the plug-in function which is subject to the suggestion activation criterion. The data type is object. This member cannot be omitted.

"sid": "*tree-SID*"

Specifies the tree SID. Possible characters conform to the specifications of the tree SID. The plug-in function is executed by specifying the configuration information SID associated with the specified tree SID. If multiple configuration information SIDs are associated with the specified tree SID, the plug-in function is executed by specifying one configuration information SID, and if it is executed successfully, the criterion is evaluated with the response of the plug-in function. The subsequent configuration information SIDs are ignored.

The order of specifying configuration information SIDs is undefined.

If the `args.setError` method is executed in the plug-in, or if `suggestion` is not found in the member of the response, a failure in the execution of the plug-in function is determined, resulting in execution of the plug-in function with the next configuration information SID.

If the execution of the plug-in function fails with the all configuration information SIDs, obtaining criterion information fails. The data type is string. This member can be omitted. If it is omitted, the system assumes that the selected node is specified.

"method": "*name-of-the-plug-in-function*"

Specifies the name of the plug-in function. After adding the plug-in function, check if the JP1/IM3-Manager service is restarted. The plug-in function to be specified must meet all of the following conditions:

- It is modularized in `module.exports`.
- It has only the `args` argument of object type.
- It returns the response with the `args.setResult(Object result)` method, not with `return`. Specify the response for `result`.
- It notifies an error with the `args.setError(String message)` method, not via an exception. Specify the error message for `message`.
- `suggestion` (data type: string) is found in the member of the response.

The data type is string. This member cannot be omitted.

For details about the plug-in function, see [4. User-created Plug-ins](#).

"args": "*arguments-of-the-plug-in-function*"

Specifies arguments of the plug-in function to be executed. If there is no information to pass, specify an empty object. The specified object is passed to the `args.methodArgs` argument of the plug-in function to be executed. For details about other values passed to `args` of the plug-in function, see [5.7.1 Plug-in processing execution](#).

The data type is object. This member cannot be omitted.

"ope": "*comparison-keyword*"

Specifies a keyword for comparison. Possible values are as follows:

- IN: The value of `suggestion` in the response of the plug-in function specified in `key` matches the value specified for `val`.
- NOTIN: The value of `suggestion` in the response of the plug-in function specified in `key` does not match the value specified for `val`.
- REGEX: The value of `suggestion` in the response of the plug-in function specified in `key` partly matches the value specified for `val` by a regular expression.

The data type is string. This member cannot be omitted.

"val": "*value-to-be-compared-with*"

Specifies the value to be compared with the value of `suggestion` in the response of the plug-in function. Specify a string of less than 1 megabyte in size. The data type is string. This member cannot be omitted.

For details about the cache and description members, see the description for each member in [\(1\) Suggestion activation criteria](#).

## Example

Here is an example of evaluating whether the suggestion member of the following plug-in function has the OK value:

- Target IM management node: Selected IM management node
- Plug-in function: `jplpfmSuggestionCreateReportURL`

The function creates the URL of a JP1/PFM report. For details about the `jplpfmSuggestionCreateReportURL` function, see the *JP1/Performance Management Reference*.

- Argument: ID of the report

```
{
  "type": "plugin",
  "key": {
    "sid": "${.:tree:sid:}",
    "method": "jplpfmSuggestionCreateReportURL",
    "args": {
      "reportId": "ac102ce0:3b9952:ec20ca1bfc:-7b99"
    }
  },
  "ope": "NOTIN",
  "val": "",
  "description": "Successful creation of the report URL"
}
```

## (f) Suggestion activation criterion when type is set to cmd

When `type` (type of criterion) is set to `cmd`, the execution result of the command (the return value, standard output, and standard error output) can be specified as a suggestion activation criterion.

## Format

```
{
  "type": "cmd",
  "key": {
    "host": "execution-host-name-of-the-command",
    "cmd": "command-to-be-executed",
    "env": "environment-variables",
    "envFile": "environment-variable-file-name",
    "param": "type-of-the-command-execution-result"
  },
  "ope": "comparison-keyword",
  "val": "value-to-be-compared-with",
  "cache": "availability-of-criterion-information-cache",
  "description": "description-of-the-criterion"
}
```

## Information that is specified

### "key"

This is an object that specifies the information on the command which is subject to the suggestion activation criterion. The data type is object. This member cannot be omitted.

`host` : "*execution-host-name-of-the-command*"

Specifies the execution host name of the command. The range allowed is from 1 to 254 bytes. The data type is string. This member cannot be omitted.

`"cmd"` : "*command-to-be-executed*"

Specifies the command to be executed and its arguments. The range allowed is from 1 to 4,095 bytes.

Enclose the command name containing any space characters in double quotation marks ("). The data type is string. This member cannot be omitted.

`"env"` : "*environment-variables*"

Specifies the environment variable values as the value of the object, using the environment variables when the command is executed on the execution host as the key of the object.

You can specify up to 30 variables. Specify the keys and values of the objects in the range from 1 to 7,107 bytes in total. The data type is object. This member can be omitted.

`"envFile"` : "*environment-variable-file-name*"

Specifies the name of the file on the execution host in absolute path format. The range allowed is from 1 to 255 bytes. The data type is string. This member can be omitted.

`"param"` : "*value-to-be-compared-with*"

Specifies the target to be compared with. Possible values are as follows:

- `rc`: Return value
- `stdout`: Standard output
- `stderr`: Standard error output

The data type is string. This member cannot be omitted.

`"ope"` : "*comparison-keyword*"

Specifies a keyword for comparison. Possible values are as follows:

- `IN`: The value of `param` for the command specified in `key` matches the value specified for `val`.
- `NOTIN`: The value of `param` for the command specified in `key` does not match the value specified for `val`.
- `REGEX`: The value of `param` for the command specified in `key` partly matches the value specified for `val` by a regular expression.
- `GT`: The value of `param` for the command specified in `key` is greater than the value specified for `val`.
- `LT`: The value of `param` for the command specified in `key` is less than the value specified for `val`.

For details about the combinations of `param` and `ope` available, see [Table 2-12](#).

The data type is string. This member cannot be omitted.

`"val"` : "*value-to-be-compared-with*"

Specifies the value to be compared with the execution result of the command. Possible values vary depending on the value specified for `param`. For details, see the table below. Note that if the type is string, you must specify a string of less than 1 megabyte in size. This member cannot be omitted.

Table 2–12: Combinations of `param`, `ope`, and the type of `val` available for `cmd`

| No. | param value     | Value available for ope                                                                                                  | Type of val | Value to be specified for val                             |
|-----|-----------------|--------------------------------------------------------------------------------------------------------------------------|-------------|-----------------------------------------------------------|
| 1   | <code>rc</code> | <ul style="list-style-type: none"><li>• <code>IN</code></li><li>• <code>NOTIN</code></li><li>• <code>GT</code></li></ul> | number      | Value to be compared with the return value of the command |

| No. | param value | Value available for ope                                                                  | Type of val | Value to be specified for val                                        |
|-----|-------------|------------------------------------------------------------------------------------------|-------------|----------------------------------------------------------------------|
|     |             | <ul style="list-style-type: none"> <li>• LT</li> </ul>                                   |             |                                                                      |
| 2   | stdout      | <ul style="list-style-type: none"> <li>• IN</li> <li>• NOTIN</li> <li>• REGEX</li> </ul> | string      | Value to be compared with the standard output from the command       |
| 3   | stderr      | <ul style="list-style-type: none"> <li>• IN</li> <li>• NOTIN</li> <li>• REGEX</li> </ul> | string      | Value to be compared with the standard error output from the command |

If a variable is specified in a suggestion activation criterion with the `type` of `cmd`, the following character conversion is performed after the conversion of the variable:

- If the variable specified in the suggestion activation criterion contains any of the following control characters, it is converted into a half-width space character (0x20):
  - 0x01 to 0x1F (except a tab (0x09))
  - 0x7F
- The character conversion is performed according to the configuration file for converting information. For details, see [Configuration file for converting information \(event\\_info\\_replace.conf\)](#) in *Chapter 2. Definition Files*.

For details about the `cache` and `description` members, see the description for each member in *(1) Suggestion activation criteria*.

### Example

Here is an example of evaluating whether the standard output from the command with the following conditions contains `DISPLAY_NAME: JP1/AJS service` (whether the JP1/AJS service is running).

- Execution host name of the command: Node name of the selected IM management node<sup>#</sup>  
#: Node of the JP1/AJS manager host
- Command to be executed: `sc query`
- Environment variable file name: `C:\envFile.txt` on the target host
- Type of the command execution result: Standard output

```
{
  "type": "cmd",
  "key": {
    "host": "${.:tree:value.label:}",
    "cmd": "sc query",
    "envFile": "C:\\envFile.txt",
    "param": "stdout"
  },
  "ope": "REGEX",
  "val": "DISPLAY_NAME: JP1/AJS3",
  "description": "The JP1/AJS service is running"
}
```

### (g) Suggestion activation criterion when type is set to struct

When `type` (type of criterion) is set to `struct`, whether the configuration of a specific IM management node exists can be specified as a suggestion activation criterion.

## Format

```
{
  "type": "struct",
  "key": {
    "idType": "type-of-the-node",
    "sid": "configuration-information-SID-or-tree-SID"
  },
  "ope": "comparison-keyword",
  "val": "value-to-be-compared-with",
  "description": "description-of-the-criterion"
}
```

## Information that is specified

### "key"

This is an object that specifies the information on the IM management node which is subject to the suggestion activation criterion. The data type is object. This member cannot be omitted.

#### "idType": "type-of-the-node"

Specifies the ID type of the target node. Possible values are as follows:

- target: Configuration information SID
- tree: Tree SID

The data type is string. This member cannot be omitted.

#### "sid": "configuration-information-SID-or-tree-SID"

Specifies the configuration information SID or tree SID. Possible characters conform to the SID specifications.

If the conversion of the variable specified as an `sid` member fails, the system considers the SID as not existing, instead of regarding the evaluation as a failure, and continues processing when the conversion failure is caused by either of the following:

- The target node does not exist.
- The target type is set to `target` or `target [product-name]`, but the SID of the applicable configuration information does not exist.

The data type is string. This member cannot be omitted.

### "ope": "comparison-keyword"

Specifies a keyword for comparison. A possible value is as follows:

- EXIST: Whether the IM management node that meets the conditions specified in `key` exists

The data type is string. This member cannot be omitted.

### "val": "value-to-be-compared-with"

Specifies whether the IM management node with the conditions specified in `key` exists.

Specify either `true` or `false`. Specify `true` if the IM management node exists, or `false` if it does not.

The data type is Boolean. This member cannot be omitted.

For details about the `description` member, see the description in [\(1\) Suggestion activation criteria](#).

## Example

Here is an example of evaluating whether the IM management node of JP1/AJS - Agent on the same host as the selected IM management node of JP1/PFM - Agent exists.

- ID type: Tree SID
- SID: SID that meets the following conditions:
- A tree SID agrees with that of the selected JP1/PFM - Agent in the part of the tree SID from the beginning to the three-level higher IM management node (IM management node of the host).
- The tree SID after the host is the following tree SID that indicates JP1/AJS-Agent:  
\_CATEGORY\_managementApplications/\_OBJECT\_JP1AJSAGT

```
{
  "type": "struct",
  "key": {
    "idType": "tree",
    "sid": "${../../:tree:sid:}/_CATEGORY_managementApplications/_OBJECT_JP1AJSAGT"
  },
  "ope": "EXIST",
  "val": true,
  "description": "A node of JP1/AJS - Agent exists on the same host as the selected IM management node of JP1/PFM - Agent"
}
```

## (2) Response action

The following describes the response action.

### Response action format

```
{
  "type": "type-of-response-action",
  "params": "parameters-of-the-response-action",
  "description": "description-of-the-response-action"
}
```

### Response action definition

**"type": "type-of-response-action"**

Specifies the type of response action. Possible values are as follows:

- **restApi**: Specify this type when you define the execution of the REST API.
- **plugin**: Specify this type when you define the execution of a product plug-in.
- **cmd**: Specify this type when you define the execution of a command.
- **eventStatus**: Specify this type when you define the change in the event status of an event.
- **jump**: Specify this type when you define a jump to a particular URL or the Repeated event list window.

The data type is string. This member cannot be omitted.

Note that you specify **cmd** when JP1/Base on the execution host of the command is version 12-10 or later. If the version is earlier than 12-10, the command execution fails, and the return value of 0 as well as empty standard output and standard error output are returned.

**"params": "parameters-of-the-response-action"**

Specifies the parameters of the response action. Possible members vary depending on **type**. The data type is object. This member cannot be omitted.

`"description": "description-of-the-response-action"`

Specifies the description of the response action. A string of up to 512 characters without any control character can be specified. An empty string is not allowed.

The data type is string. This member cannot be omitted.

## (A) Possible values for each response action type

Different values can be specified for members depending on `type` (response action type) of the response action. The following describes the values available for each `type`. Note that you can specify the `description` member regardless of what `type` is.

### (a) Response action when `type` is set to `restApi`

When `type` (response action type) is set to `restApi`, the execution of the REST API can be specified as response action.

#### Format

```
{
  "type": "restApi",
  "params": {
    "method": "method-of-the-REST-API",
    "url": "URL-of-the-REST-API",
    "headers": "request-header-of-the-REST-API",
    "body": "request-body-of-the-REST-API"
  },
  "description": "description-of-the-response-action"
}
```

#### Information that is specified

`"params"`

This is an object that specifies the information on the REST API on which the response action is taken. The data type is object. This member cannot be omitted.

`"method": "method-of-the-REST-API"`

Specifies a method of the REST API. Possible values are as follows:

- GET
- HEAD
- POST
- PUT
- PATCH
- DELETE
- OPTIONS
- TRACE

The data type is string. This member cannot be omitted.

`"url": "URL-of-the-REST-API"`

Specifies the URL of the REST API. Possible characters are half-width alphanumeric characters and the following symbols that conform to the RFC 2396 specifications:

`;, /, ?, :, @, &, =, +, $, %, -, _, ., !, ~, *, ', (, ), %`

Begin the URL with `http://` or `https://`.

The data type is string. This member cannot be omitted.

When the URL including host name is specified, register the host name to the integrated manager's `hosts` file and DNS so as to enable name resolution on the integrated manager host. Configuration in the `jplhosts` file and the `jplhosts2` file are not referred.

`"headers": "request-header-of-the-REST-API"`

Specifies the request header of the REST API. The data type is object. This member cannot be omitted.

`"body": "request-body-of-the-REST-API"`

Specifies the request body of the REST API. When the `GET` or `DELETE` method is used and the body is not required, omit this member. The data type is object. This member can be omitted.

For details about the `description` member, see the description in [\(2\) Response action](#).

## Example

Here is an example of executing the REST API with the following JP1 event information:

- URL: `https://test`
- Request header  
Authentication information: `yyyy/zzzz`  
Media type of the request body: `application/json`
- Request body  
Request body parameter `body1`: `${:event[1]:B.ID:}`  
This is the event ID of the JP1 event that meets the first suggestion activation criterion with `type` specified for cases set to event.
- Request body parameter `body2`: `${:event[1]:B.MESSAGE:}`  
This is the message of the JP1 event that meets the first suggestion activation criterion with `type` specified for cases set to event.

```
{
  "type": "restApi",
  "params": {
    "method": "POST",
    "url": "https://test",
    "headers": {
      "Authorization": "yyyy/zzzz",
      "Content-Type": "application/json"
    },
    "body": {
      "body1": "${:event[1]:B.ID:}",
      "body2": "${:event[1]:B.MESSAGE:}"
    }
  },
  "description": "Use JP1 event information to execute a REST API test"
}
```

## (b) Response action when type is set to plugin

When `type` (response action type) is set to `plugin`, the execution of a plug-in function can be specified as response action.

## Format

```
{
  "type": "plugin",
  "params": {
    "sid": "tree-SID",
    "method": "name-of-the-plug-in-function",
    "args": "arguments-of-the-plug-in-function"
  },
  "description": "description-of-the-response-action"
}
```

## Information that is specified

### "params"

This is an object that specifies the information on the plug-in function on which the response action is taken. The data type is object. This member cannot be omitted.

#### "sid": "tree-SID"

SID. The plug-in function is executed by specifying the configuration information SID associated with the specified tree SID. If multiple configuration information SIDs are associated with the specified tree SID, the plug-in function is executed by specifying one configuration information SID, and if it is executed successfully, the subsequent configuration information SIDs are ignored. The order of specifying configuration information SIDs is undefined.

If the `args.setError` method is executed in the plug-in, a failure in the execution of the plug-in function is determined, resulting in execution of the plug-in function with the next configuration information SID.

The data type is string. This member can be omitted. If it is omitted, the system assumes that the selected node is specified.

#### "method": "name-of-the-plug-in-function"

Specifies the name of the plug-in function. After adding the plug-in function, check if the JP1/IM3-Manager service is restarted. The plug-in function to be specified must meet all of the following conditions:

- It is modularized in `module.exports`.
- It only has the `args` argument of object type.
- It returns the response with the `args.setResult(Object result)` method, not with `return`. Specify the response for `result`.
- It notifies an error with the `args.setError(String message)` method, not via an exception. Specify the error message for `message`.
- The function name does not start with two underscores (`__`).

The data type is string. This member cannot be omitted.

#### "args": "arguments-of-the-plug-in-function"

Specifies arguments of the plug-in function to be executed. If there is no information to pass, specify an empty object. The specified object is passed to the `args.methodArgs` argument of the plug-in function to be executed. For details about other values passed to `args` of the plug-in function, see [5.7.1 Plug-in processing execution](#).

The data type is object. This member cannot be omitted.

For details about the `description` member, see the description in [\(2\) Response action](#).

## Example

Here is an example of executing the plug-in function under the following conditions:

- Target IM management node: Selected IM management node
- Plug-in function: `jplpfmSuggestionSetStatusOfEventsToProcessed`

This function turns a JP1 event into processed. For details about the `jplpfmSuggestionSetStatusOfEventsToProcessed` function, see the *JP1/Performance Management Reference*.

- Argument: Event SID

This is the value of response suggestion of the plug-in function that was executed under the third suggestion activation criterion with type specified for cases set to plugin.

```
{
  "type": "plugin",
  "params": {
    "sid": "${.tree:sid:}",
    "method": "jplpfmSuggestionSetStatusOfEventsToProcessed",
    "args": {
      "eventSids": "${:plugin[3]:}"
    }
  },
  "description": "Turn the alarm or the event status of the event on an agent in normal status into Processed"
}
```

If linkage with JP1/PFM is enabled, the plug-in methods of JP1/PFM will be available. For details, see the *JP1/Performance Management User's Guide*.

## (c) Response action when type is set to cmd

When type (response action type) is set to cmd, the execution of the command can be specified as response action.

### Format

```
{
  "type": "cmd",
  "params": {
    "host": "execution-host-of-the-command",
    "cmd": "command-to-be-executed",
    "env": "environment-variables",
    "envFile": "environment-variable-file-name"
  },
  "description": "description-of-the-response-action"
}
```

### Information that is specified

#### "params"

This is an object that specifies the information on the command on which the response action is taken. The data type is object. This member cannot be omitted.

"host": "execution-host-of-the-command"

Specifies the execution host name of the command. The range allowed is from 1 to 254 bytes. The data type is string. This member cannot be omitted.

"cmd": "*command-to-be-executed*"

Specifies the command to be executed and its arguments. The range allowed is from 1 to 4,095 bytes.

Enclose the command name containing any space characters in double quotation marks ("). The data type is string. This member cannot be omitted.

"env": "*environment-variables*"

Specifies the environment variable values as the value of the object, using the environment variables when the command is executed on the execution host as the key of the object.

You can specify up to 30 variables. Specify the keys and values of the objects in the range from 1 to 7,107 bytes in total. The data type is object. This member can be omitted.

"envFile": "*environment-variable-file-name*"

Specifies the name of the file on the execution host in absolute path format. The range allowed is 1 to 255 bytes. The data type is string. This member can be omitted.

If a variable is specified in a response action with the `type` of `cmd`, the following character conversion is performed after the conversion of the variable:

- If the variable specified in a response action contains any of the following control characters, it is converted into a half-width space character (0x20):
  - 0x01 to 0x1F (except a tab (0x09))
  - 0x7F
- The character conversion is performed according to the configuration file for converting information. For details, see [Configuration file for converting information \(event\\_info\\_replace.conf\)](#) in *Chapter 2. Definition Files*.

For details about the `description` member, see the description in [\(2\) Response action](#).

## Example

Here is an example of executing the command under the following conditions:

- Execution host name of the command: Node name of the selected IM management node (node of a JP1/IM host)
- Command to be executed: "C:\Program Files (x86)\Hitachi\JP1IMM\tools\jim\_log" -f C:\\temp -q  
This is the data collection command of JP1/IM.
- Environment variable file name: C:\envFile.txt on the target host

```
{
  "type": "cmd",
  "params": {
    "host": "${.:tree:value.label:}",
    "cmd": "\"C:\\Program Files (x86)\\Hitachi\\JP1IMM\\tools\\jim_log\\  
\" -f C:\\\\temp -q\"",
    "envFile": "C:\\envFile.txt"
  },
  "description": "Execution of the data collection command of JP1/IM"
}
```

## (d) Response action when type is set to eventStatus

When `type` (response action type) is set to `eventStatus`, a change in the event status of a JP1 event can be specified as response action.

## Format

```
{
  "type": "eventStatus",
  "params": {
    "dealt": event-status,
    "sid": "JP1-event-SID, ..."
  },
  "description": "description-of-the-response-action"
}
```

## Information that is specified

### "params"

This is an object that specifies the event and its event status on which the response action is taken. The data type is object. This member cannot be omitted.

#### "dealt": event-status

Specifies the new event status. The following values can be specified:

- 0: Unprocessed
- 1: Processed
- 2: Processing
- 3: Held

The data type is number. This member cannot be omitted.

#### "sid": "JP1-event-SID"

Specifies the SIDs of JP1 events whose status you want to get.

If you specify SIDs of multiple JP1 events, use commas ( , ) to concatenate the SIDs of the JP1 events. Possible characters conform to the SID specifications. You can specify SIDs of events from 1 to 2,000. The data type is string. This member cannot be omitted.

For details about the `description` member, see the description in [\(2\) Response action](#).

## Example

Here is an example of changing the event status of an event to 1 (Processed) under the following condition:

- Event SID: `${:event[1]:sid:},${:event[2]:sid:}`

This is the event SID of the JP1 event that meets the first and second suggestion activation criteria with `type` specified for cases set to event.

```
{
  "type": "eventStatus",
  "params": {
    "dealt": 1,
    "sid": "${:event[1]:sid:},${:event[2]:sid:}"
  },
  "description": "Change the event ID: ${:event[1]:B.ID:}, ${:event[2]:B.ID:} to Processed"
}
```

## (e) Response action when type is set to jump

When `type` (response action type) is set to `jump`, a jump to a particular URL or the Repeated event list window can be specified as a response action.

### Format

```
{
  "type": "jump",
  "params": {
    "url": "URL",
    "target": "target-attribute-of-HTML",
    "relatedEvent": repeated-event-list-window-information
  },
  "description": "description-of-the-response-action"
}
```

### Information that is specified

#### "params"

This is an object that specifies the information on the jump destination on which the response action is taken. The data type is object. This member cannot be omitted.

#### "url": "URL"

Specify the URL of a jump destination in either of the following formats.

Possible characters are half-width alphanumeric characters and the following symbols that conform to the RFC 2396 specifications:

`;, /, ?, :, @, &, =, +, $, %, -, _, ., !, ~, *, ', (, ), %`

Begin the URL with one of `http://`, `https://`, or `index?`.

- Any URL

Specify a given URL.

- Direct access URL of JP1/IM

Specify a direct access URL of JP1/IM by using `index` in the Integrated Operation Viewer window. The window currently open jumps to the specified URL, without refreshing the window. For details about the format of the direct access URL, see *4.12 Setting up the direct access URL* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

The data type is string. You must specify either this member or the `relatedEvent` member.

#### "target": "target-attribute-of-HTML"

Specify the HTML `target` attribute when the URL of the jump destination is opened. If it is omitted, the system assumes that `_blank` is specified. The following values cannot be specified:

- `_self`
- `_parent`
- `_top`
- Value starting with `JP1IM_`

If the `url` member is omitted or a URL starting with `index` is specified for the value of the `url` member, the value of the `target` member is ignored. The data type is string. This member can be omitted.

"relatedEvent":*search-criterion-number*

Specify it when you show the Repeated event list window. The target events are those that are searched for under the suggestion activation criteria with `type` set to `event`. Specify a suggestion activation criterion number from 1 to 100 of suggestion activation criteria with `type` specified for cases set to `event`.

If more than one JP1 event that meets the criterion is found, the Repeated event list window for the JP1 event with the latest registration date and time is displayed.

The data type is number. You must specify either this member or the `url` member.

For details about the `description` member, see the description in (2) *Response action*.

### Example 1

Here is an example of jumping to a specific URL by specifying a target name:

```
{
  "type": "jump",
  "params": {
    "url": "https://sample/web/application",
    "target": "sampleWebApplication"
  },
  "description": "Jump to https://sample/web/application"
}
```

### Example 2

Here is an example of specifying a direct access URL:

```
{
  "type": "jump",
  "params": {
    "url": "index?sid=${../..:tree:sid:URLENC}%2F%5FCATEGORY%5FmanagementApplications%2F%5FOBJECT%5FJP1AJSAGT&view=tree&eu=1"
  },
  "description": "Screen transition of JP1/IM (JP1/AJS - Manager node on the same host)"
}
```

### Example 3

Here is an example of specifying the Repeated event list window:

```
{
  "type": "jump",
  "params": {
    "relatedEvent": 1
  },
  "description": "Open the Repeated event list window"
}
```

## (3) Variable

You can specify variables for suggestion activation criteria and response actions. With variables, the information and current time of the selected IM management node can be replaced with the information obtained when the suggestion activation criterion is evaluated. The use of variables allows you to dynamically define suggestion activation criteria and response actions.

Example of specifying suggestion activation criteria with variables

Suggestion activation criteria

- Suggestion activation criterion 1: A JP1 event with the event ID of xxx exists.
- Suggestion activation criterion 2: JP1 events with the registration date and time that falls on or after *the registration date and time of the event which meets suggestion activation criterion 1* exists.

Define *the registration date and time of the event which meets suggestion activation criterion 1* as a variable. When a variable is specified in suggestion activation criteria, it is converted when each suggestion activation criterion is evaluated. If the evaluation is skipped, the variable is not converted. For details about skipping the evaluation, see the description in [\(1\) Suggestion activation criteria](#).

Variables specified in a response action are converted after suggestion criteria of the response action are evaluated. If the evaluation result is false, the variables are not converted.

### Example

```
"cases": [
  ["suggestion-activation-criterion-1", "suggestion-activation-criterion-2"],
  ["suggestion-activation-criterion-3"]
],
"action": "response-action"
```

In the above example, the processing is performed in the following order:

1. Convert variables specified in suggestion activation criterion 1
2. Evaluate suggestion activation criterion 1 (true)
3. Convert variables specified in suggestion activation criterion 2
4. Evaluate suggestion activation criterion 2 (false)
5. Convert variables specified in suggestion activation criterion 3
6. Evaluate suggestion activation criterion 3 (true)
7. Convert variables specified in the response action
8. Suggest the response action

You can specify variables in suggestion activation criteria, string-type members of response actions (other than `type`), string-type elements of arrays, and string-type members of objects (except for the member name). The format of a variable is as follows:

```
${"target-node":"type-of-target":"target-key":"encoding-type"}
```

### ! Important

The colons (:) in the variable format cannot be omitted. Furthermore, \$, {, and } are not available in the target node. :, \$, {, and } are not available in the type of target, the target key, and the encoding type.

### (A) Target node

Specify the IM management node from which information is obtained, in the relative path format from the tree SID or the selected IM management node. It can be omitted depending on the type of conversion target of the variable. For details, see [Table 2-14 Possible values for the type of target](#). If a target node is specified for the type of target that does not require it, it is ignored.

The table below describes the format of the relative path. Use slashes (/) for concatenation.

Table 2–13: Format of the relative path

| No. | Format of the relative path               | Node indicated when specified at the beginning of the target node                                                                                                                                        | Node indicated when specified after the first slash (/) of the target node                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | .                                         | Specify it to indicate the selected IM management node or the node of the tree SID specified by the request of the response action suggestion API.                                                       | Not available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 2   | ..                                        | Specify it to indicate the upper-level node of the selected IM management node or the upper-level node of the tree SID specified by the request of the response action suggestion API.                   | Specify it to indicate the upper-level node of the current node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 3   | Structured identifier                     | Specify a structured identifier in the absolute path to specify a node in the absolute path format.<br>For details about possible characters in the structured identifier, see <a href="#">7.1 SID</a> . | Specify the structured identifiers of subsequent tree SIDs of the current node to specify a lower-level node of the current node.<br>For details about possible characters in the structured identifier, see <a href="#">7.1 SID</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 4   | <i>link-direction</i> < <i>linkType</i> > | Not available.                                                                                                                                                                                           | Specify it to indicate a related node by using the current node and the link for the type of link information < <i>linkType</i> >.<br>You can specify whichever link information of the tree SID or the configuration information SID.<br>You can specify either of the following for <i>link-direction</i> : <ul style="list-style-type: none"> <li>&lt;: Preceding node</li> <li>&gt;: Succeeding node</li> </ul> Tree cannot be specified for < <i>linkType</i> >.<br>In addition, if there are multiple links that correspond to <i>link-direction</i> < <i>linkType</i> >, the system assumes that the related node of the first link is specified for operation. For details about characters available in < <i>linkType</i> >, see the description of <i>type</i> ( <i>information-type</i> ) in <i>IM management node link definition file (imdd_nodeLink_def.conf)</i> in <a href="#">Chapter 2. Definition Files</a> . |

## (B) Type of target

In the type of target, specify the type of target of conversion, i.e., how a variable is converted, such as when a variable is converted into event information or a REST API execution result. The following table describes the values available for the type of target.

Table 2–14: Possible values for the type of target

| No. | Type of target                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Necessity of specifying the target node |
|-----|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| 1   | <code>target[product-name]</code> | A variable is converted into the SID information of configuration information created by the product plug-in of <code>[product-name]</code> in the SIDs of the configuration information of the target node.<br>If the target node has multiple SIDs of configuration information created by the product plug-in of the target, a variable is converted into the SID information of the configuration information obtained first. The order of obtaining the information is undefined. | Required                                |

| No. | Type of target | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Necessity of specifying the target node |
|-----|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
|     |                | <p>You can omit <code>[product-name]</code>. If it is omitted, a variable is converted into the SID information of the configuration information obtained first. The order of obtaining the information is also undefined in this case.</p> <p>The value specified <code>[product-name]</code> can accept the same value that can be specified for <code>product</code> in the target host definition file for configuration collection. For details, see <a href="#">Target host definition file for configuration collection (imdd_target_host.conf)</a> in Chapter 2. Definition Files.</p> |                                         |
| 2   | tree           | A variable is converted into the information of the tree SID of the target node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Required                                |
| 3   | time           | A variable is converted into the time information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Optional                                |
| 4   | event[n]       | <p>A variable is converted into the information of the JP1 event that meets the <i>n</i>th suggestion activation criterion in the suggestion activation criteria with <code>type</code> specified for <code>cases</code> set to <code>event</code>.</p> <p>If multiple JP1 events meet the criterion, a variable is converted into the information of the JP1 event with the most recent registration date and time.</p> <p>Specify a number from 1 to 100 for <code>[n]</code>.</p>                                                                                                           | Optional                                |
| 5   | eventCount[n]  | <p>A variable is converted into the information of the JP1 event that meets the <i>n</i>th suggestion activation criterion in the suggestion activation criteria with <code>type</code> specified for <code>cases</code> set to <code>eventCount</code>.</p> <p>If multiple JP1 events meet the criterion, a variable is converted into the information that contains the information of all applicable JP1 events altogether.</p> <p>Specify a number from 1 to 100 for <code>[n]</code>.</p>                                                                                                 | Optional                                |
| 6   | restApi[n]     | <p>A variable is converted into the information of the response of the REST API executed under the <i>n</i>th suggestion activation criterion in the suggestion activation criteria with <code>type</code> specified for <code>cases</code> set to <code>restApi</code>.</p> <p>Specify a number from 1 to 100 for <code>[n]</code>.</p>                                                                                                                                                                                                                                                       | Optional                                |
| 7   | plugin[n]      | <p>A variable is converted into the information of the execution result of the plug-in function executed under the <i>n</i>th suggestion activation criterion in the suggestion activation criteria with <code>type</code> specified for <code>cases</code> set to <code>plugin</code>.</p> <p>Specify a number from 1 to 100 for <code>[n]</code>.</p>                                                                                                                                                                                                                                        | Optional                                |
| 8   | cmd[n]         | <p>A variable is converted into the information of the execution result of the command executed under the <i>n</i>th suggestion activation criterion in the suggestion activation criteria with <code>type</code> specified for <code>cases</code> set to <code>cmd</code>.</p> <p>Specify a number from 1 to 100 for <code>[n]</code>.</p>                                                                                                                                                                                                                                                    | Optional                                |

## (C) Target key

For the target key, specify an element for the type of target of which a variable is converted. For example, specify the status code element or body element of the response for the execution of the REST API. The value that can be specified for the target key varies depending on the type of target. The following explains the target key you can specify for each type of target.

### (a) When the type of target is target

When the type of target is `target`, specify the SID element of configuration information for the target key. Possible target keys are as follows:

`sid`

A variable is converted into the value of the configuration information SID of the target node.

`value.member-name`

A variable is converted into the value of the member specified as *member-name* for the `value` value assigned to the configuration information SID of the target node.

If you want to specify more members in the object, specify them in the following format:

```
object-name.member-name
```

However, they cannot be specified if the specified member is of an array or object type.

If you convert the value of a property configured by the product plug-in that appears in the **Properties** for the related node area on the **Related node** tab in the Integrated Operation Viewer window, specify it in the following format:

```
value.property.property-name
```

### Example

Here is an example of obtaining the service ID from the SID of the selected IM management node (IM management node of the JP1/PPM agent) and executing the command to suspend monitoring.

Note that it assumes that the service ID has been obtained by specifying the following values in variables:

- Target node: Selected IM management node
- Type of target: target (Configuration information SID)
- Target key: `value.property.ServiceId` (ServiceId member of property in the Value value)

```
{
  "type": "cmd",
  "params": {
    "cmd": "\"C:\\Program Files (x86)\\Hitachi\\jplpc\\tools\\jpctool\\
monitor suspend -noquery -id ${.:target:value.property.ServiceId}\"
  },
  "description": "Execute the command to suspend monitoring of JP1/PPM"
}
```

### (b) When the type of target is tree

When the type of target is `tree`, specify the SID element of the tree for the target key. Possible target keys are as follows:

`sid`

A variable is converted into the SID value of the tree of the target node.

`value.member-name`

A variable is converted into the value of the member specified as *member-name* for the `value` value assigned to the tree SID of the target node.

If you want to specify more members in the object, specify them in the following format:

```
object-name.member-name
```

However, members of an array or object type cannot be specified.

### Example

Here is an example of specifying the tree SID of the selected node:

```
{
  "type": "event",
  "key": {
    "sid": "${.:tree:sid:}",
  }
}
```

```

    ...
  },
  ...
}

```

### (c) When the type of target is time

When the type of target is `time`, specify the relative date and time from the current time (UTC time in ISO 8601 format) for the target key. The relative date and time is specified in the following format:

```
[+|-] value.unit.segmentation
```

You can omit the target key. If it is omitted, a variable is converted into the current date and time in ISO 8601 format. Possible target keys for `time` are as follows:

[+|-]

Specify whether the target key is in the future or in the past based on the current date and time.

- `+`: The target key is converted into a future date and time.
- `-`: The target key is converted into a past date and time.

You can omit this key. If it is omitted, a variable is converted into the current time.

*value.unit*

Specify how far the time is in the future or past from the current date and time.

Specify an integer from 1 to 2147483647 as the value. Specify one of the following values as the unit:

- `y`: Year
- `M`: Month
- `d`: Day
- `h`: Hour
- `m`: Minute
- `s`: Second

When `[+|-]` is omitted, this key cannot be specified. When `[+|-]` is specified, this key cannot be omitted. Note that an error occurs if the variable is converted into the following date and time:

- Date and time before 1970-01-01T00:00:00Z
- Date and time after 9999-12-31T23:59:59Z

*segmentation*

Specify a segmented part of a specified date and time if you want to convert only part of the date and time. The following values can be specified:

- `y`: Year part
- `M`: Month part
- `d`: Day part
- `h`: Hour part
- `m`: Minute part
- `s`: Second part

You can omit this key. If it is omitted, the whole date and time is converted.

## Example

Here is an example of specifying events in the time period from yesterday's 23:00 UTC to today's 2:00 UTC under an event criterion.

Note that it assumes that the following combination of variables has been used to get *yesterday's 23:00 UTC* and *today's 2:00 UTC*.

Yesterday's 23:00 UTC

- `${:time:-1.d.y:}` Year part of the date one day before the current time
- `${:time:-1.d.M:}` Month part of the date one day before the current time
- `${:time:-1.d.d:}` Day part of the date one day before the current time

These variables get the value of *segmentation* of the date one day before the current time by specifying `time` for the type of target and `-1.d.segmentation` for the target key.

Today's 2:00 UTC

- `${:time:..y:}` Year part of the current time
- `${:time:..M:}` Month part of the current time
- `${:time:..d:}` Day part of the current time

These variables get the value of *segmentation* of the current date and time by specifying `time` for the type of target and *segmentation* for the target key.

```
{
  "type": "event",
  "key": {
    "B.TIME": [ "${:time:-1.d.y:}-${:time:-1.d.M:}-${:time:-1.d.d:}T23:00:00Z", "${:time:..y:}-${:time:..M:}-${:time:..d:}T02:00:00Z",
      ...
    ],
    ...
  }
}
```

## (d) When the type of target is event[n]

When the type of target is `event [n]`, specify the JP1 event element for the target key. Possible target keys are as follows:

*sid*

A variable is converted into the SID of the JP1 event.

*attribute-name*

A variable is converted into the attribute value of `<attribute-name>` of the JP1 event. For details about possible attribute names, see [5.6.1 Event search](#).

## Example

Here is an example of specifying the conditions where the event ID of the unprocessed event of YYYY has been issued after the event ID of the unprocessed event of XXXX under event criteria.

Note that it assumes that the condition of the YYYY event after XXXX has been specified by designating the registration date and time of the event that meets the first event criterion for the first element of `B.TIME` (registration time) of the second event criterion and designating the current time as the second element. Also note that it assumes that the registration date and time of the event that meets the first event criterion is obtained by specifying the following values for the variables:

- Type of target: `event [1]` First event criterion

- Target key: B.TIME Registration date and time of the event

```
"cases": [
  [
    {
      "type": "event",
      "key": {
        "sid": "${.:tree:sid:}",
        "statusFilter": [30],
        "B.ID": ["XXXX"],
        "E.@JP1IM_DEALT": [0]
      },
      ...
    },
    {
      "type": "event",
      "key": {
        "sid": "${.:tree:sid:}",
        "statusFilter": [30],
        "B.TIME": ["${:event[1]:B.TIME:}", "${:time::}"],
        "B.ID": ["YYYY"],
        "E.@JP1IM_DEALT": [0]
      },
      ...
    }
  ]
]
```

#### (e) When the type of target is eventCount[n]

When the type of target is eventCount [n], specify the JP1 event element for the target key. Possible target keys are as follows:

sid

A variable is converted into the SID of the JP1 event. If multiple JP1 events meet the criterion, it is converted into a string with each event separated by a comma (,).

#### Example

Here is an example of using the response action for changing the event statuses of JP1 events to change all JP1 events that meet the event criterion to Processed.

```
{
  "type": "eventStatus",
  "params": {
    "sid": "${:eventCount[1]:sid:}",
    "dealt": 1
  },
  "description": "Change all the applicable JP1 events to Processed"
}
```

#### (f) When the type of target is restApi[n]

When the type of target is restApi [n], specify the response of the REST API for the target key. Possible target keys are as follows:

status

A variable is converted into the status code of the response of the REST API.

headers

A variable is converted into the response header of the REST API. For details about the format after the conversion, see the description in *Format of the string for the REST API response header* of (1)(d) Suggestion activation criterion when type is set to restApi.

body

A variable is converted into the response body of the REST API.

### Example

Here is an example of specifying the response body of the REST API executed under a REST API criterion, as an argument of the response action on the execution of a plug-in function.

Note that it assumes that the response body of the REST API executed under the REST API criterion is obtained by specifying the following values for the variables:

- Type of target: restApi[1] First REST API criterion
- Target key: body Response body

```
"cases": [
  [
    {
      "type": "restApi",
      ...
    }
  ]
  ...
  "action": {
    "type": "plugin",
    "params": {
      ...
      "args": {
        "apiResponse": "${:restApi[1]:body:}"
      }
    },
    ...
  }
}
```

### (g) When the type of target is plugin[n]

When the type of target is plugin[n], you do not have to specify the target key. The plug-in function specified in key of a suggestion activation criterion is converted into the value of the suggestion member in the object passed to the args.setResult method.

### Example

Here is an example of specifying the response of the plug-in function executed under a plug-in criterion, as an argument of the response action on the execution of a plug-in function.

Note that it assumes that the response of the plug-in function executed under the plug-in criterion is obtained by specifying the following values for the variables:

- Type of target: plugin[1] Plug-in function criterion
- Target key: Not specified

```
"cases": [
  [
    {
      "type": "plugin",

```

```

        ...
    }
]
...
"action": {
    "type": "plugin",
    "params": {
        ...
        "args": {
            "pluginResult": "${:plugin[1]::}"
        }
    },
    ...
}

```

#### (h) When the type of target is cmd[n]

When the type of target is `cmd[n]`, specify the execution result element of the command for the target key. Possible target keys are as follows:

`rc`

A variable is converted into the return value of the command.

`stdout`

A variable is converted into the standard output of the command.

`stderr`

A variable is converted into the standard error output of the command.

#### Example

Here is an example of specifying the standard output of the command executed under a command execution criterion, as an argument of the response action on the execution of a plug-in function.

Note that it assumes that the standard output of the command executed under the command execution criterion is obtained by specifying the following values for the variables:

- Type of target: `cmd[1]` First command criterion
- Target key: `stdout` Standard output

```

"cases": [
    [
        {
            "type": "cmd",
            ...
        }
    ]
]
...
"action": {
    "type": "plugin",
    "params": {
        ...
        "args": {
            "cmdStdOut": "${:cmd[1]:stdout:}"
        }
    },
    ...
}

```

```
} . . .
```

## (i) Encoding type

Specify the encoding type when you encode variables when they are converted. You can omit the encoding type. If it is omitted, the variables are not encoded.

Possible encoding types are as follows:

- ENC: The variables are Base64-encoded.
- URLENC: The variables are URL-encoded.

## Notes

- Grant the Administrator permissions in Windows, or the root permissions in UNIX, to the suggestion definition file.
- You can use regular expressions in the suggestion definition file. In this case, it may take time for mapping if you make heavy use of `. *`, which matches all characters. When you use `. *`, place the regular expression only where needed.
- Regular expressions in the suggestion definition file use partial matching, and thus an expression with `. *` at the beginning and end indicates the same condition as one without `. *` at the beginning and end.

For example, examples 1 and 2 below are the same condition:

Example 1: Regular expression that matches a string that contains `_OBJECT_JP1IMMGR`

`. *_OBJECT_JP1IMMGR. *`

Example 2: Regular expression that matches a string that contains `_OBJECT_JP1IMMGR`

`_OBJECT_JP1IMMGR`

It may take time for search if `. *` is placed at the beginning and end, so avoid specifying `. *` there.

- If either of the following conditions is met when regular expressions are used, the `KAJY22042-W` message is displayed when the `jddupdatesuggestion` command is executed:
  - As a regular expression, `. *` is placed at the beginning or at the end.
  - As a regular expression, consecutive use of `. *` is made.

For details about the `KAJY22042-W` message, see the *JP1/Integrated Management 3 - Manager Messages*.

- It may take time to evaluate suggestion activation criteria depending on the amount of suggestion information that is displayed on one IM management node. Perform trial operation adequately until you are sure that there is no problem.

## Definition example

The following explains a definition example of the suggestion definition file under the conditions below.

### Suggestion display criteria

- Suggestions are displayed on the JP1/PFM - Agent node to which health check events are mapped.
- The JP1 permission of `JP1_AJS_Admin` or `JP1_AJS_Editor` is granted to the user.
- Suggestion activation criteria
  - The JP1/AJS - Agent node exists on the same host as the selected IM management node, to which a health check event indicating that the host stopped was issued within the past one hour, and the event status is now `Unprocessed`.

## Response action

- Navigate the window to the **Related node** tab on the JP1/AJS - Agent that exists on the same host as the selected IM management node.

Figure 2–2: Example of the tree structure when JP1/AJS - Agent and JP1/PFM - Agent exist on the same host

In the above figure, *JP1/AJS3 - Agent* represents the JP1/AJS - Agent node. The tree SID is as follows:

```
_ROOT_AllSystems/_HOST_HOSTA/_CATEGORY_managementApplications/_OBJECT_JP1AJS_AGT
```

In the above figure, *HostA<Windows>* represents the JP1/PFM - Agent node to which the health check event is mapped. The tree SID is as follows:

```
_ROOT_AllSystems/_HOST_HOSTA/_CATEGORY_managementApplications/_SUBCATEGORY_JP1%2FPFM%20-%20Windows/_OBJECT_JP1PFM-A-TA1HostAJP1AGENTSERVICE
```

The following shows the definition in the suggestion definition file:

```
{
  "meta":{
    "version":"1"
  },
  "suggestions":[
    {
      "suggestionId":"check_affected_rootJobnet",
      "label":"Impact on root jobnets affected by host going down",
      "node":"CATEGORY_managementApplications.*_OBJECT_JP1PFM-A",
      "permissions":[]
    }
  ]
}
```

```
[ "JP1_AJS_Admin"],
["JP1_AJS_Editor"]
],
"cases": [
[
{

}
}
]
```

### ◆ Single sign-on mapping definition file (imdd\_sso\_mapping.properties)

## Format

```

user-ID-for-the-OpenID-provider = JP1-user-name
user-ID-for-the-OpenID-provider = JP1-user-name
...

```

## Files

`imdd_sso_mapping.properties`

`imdd_sso_mapping.properties.model` (model file of the single sign-on mapping definition file)

## Storage directory

In Windows

For a physical host:

*Manager-path*\conf\imdd\

For a logical host:

*shared-folder*\jplimm\conf\imdd\

In UNIX

For a physical host:

*/etc/opt/jplimm/conf/imdd/*

For a logical host:

*shared-directory/jplimm/conf/imdd/*

## Description

This file defines the mapping between the name of the JP1 user used in the Intelligent Integrated Management Base and the name of the user registered in the OpenID provider.

## When the definitions are applied

When the `jddupdatesomap` command is completed successfully, the settings in the single sign-on mapping definition file take effect in the Intelligent Integrated Management Base.

## When the definitions are applied

When the `jddupdatesomap` command is completed successfully, the settings in the single sign-on mapping definition file take effect in the Intelligent Integrated Management Base.

## Information that is specified

Save the single sign-on mapping definition file in UTF-8 format, with no byte order mark (BOM) added to it.

The single sign-on mapping definition file has the following rules:

- Comment lines start with # or !.
- The user ID for the OpenID provider and the JP1 user name are case-sensitive.
- If an invalid format is found in a line, processing continues, ignoring the line.
- When you specify multiples user IDs for the same OpenID provider, the last specified one is enabled.
- There is no upper limit on the number of definitions.
- If the definition is applied when the file has no valid property at all, the `KAJY52031-W` message is output and the applied single sign-on mapping definitions are cleared.

*user-ID-for-the-OpenID-provider*

Specify the user ID registered in the OpenID provider. It is mapped to the JP1 user name specified on the right side.

## JP1-user-name

Specify the name of the JP1 user registered in the JP1/Base authentication server. It is mapped to the user ID registered in the OpenID provider specified on the left side.

For details about the characters available in the JP1 user name, see the *JP1/Base User's Guide*.

The JP1 user requires the JP1 permission level of JP1\_Console\_Admin, JP1\_Console\_Operator, or JP1\_Console\_User, which is needed to log in to the Intelligent Integrated Management Base. If an unregistered JP1 user or a JP1 user without the JP1 permission is specified, the KAJY52027-E error occurs upon user authentication.

DS users whose JP1 authentication information is managed in the directory server through directory server linkage of JP1/Base are not applicable for single sign-on mapping authentication. If a DS user goes through authentication when the user is specified in the single sign-on mapping definition file, the KAJY52027-E error occurs during user authentication. For details about directory server linkage of JP1/Base, see the *JP1/Base User's Guide*.

## Notes

- The user ID for the OpenID provider contains all characters, except for the end-of-line symbol, from the first non-space character to before the first unescaped =, :, or a space character.
- If you use characters that show the end of the user ID for the OpenID provider (=, :, or a space character) in the user ID, add a backslash before the end-indicating character to escape it.
- If you use characters that show the comment at the beginning of the user ID for the OpenID provider (# or !) in the user ID, add a backslash before the comment-indicating character to escape it.

The following table lists characters that must be escaped when used in the user ID for the OpenID provider.

Table 2–15: Characters that must be escaped when used in the user ID for the OpenID provider

| No. | Character | Unicode | When it must be escaped          |
|-----|-----------|---------|----------------------------------|
| 1   | =         | \u003D  | Always required                  |
| 2   | :         | \u003A  |                                  |
| 3   | Space     | \u0020  |                                  |
| 4   | #         | \u0023  | Required for the first character |
| 5   | !         | \u0021  |                                  |

## Example definition

```
OpenIDUser001 = JP1admin
OpenIDUser002 = JP1lope
...
```

## ◆ Auto response action definition file (autoactconf.json)

### Format

Same as [7.2.4\(1\) Auto Response Action definition Object](#).

The file size limit is 10MB.

## Files

autoactconf.json

## Storage directory

In Windows

For a physical host:

*Manager-path*\conf\imdd\responseaction

For a logical host:

*shared-folder*\jplimm\conf\imdd\responseaction

In UNIX

For a physical host:

/etc/opt/jplimm/conf/imdd/responseaction

For a logical host:

*shared-directory*/jplimm/conf/imdd/responseaction

## Character code

UTF-8 (If file has a BOM, load it ignoring BOM)

## Description

A file that restores execution conditions in automatic response action and automatic response action definition, which is executed contents are recorded

## When the definitions are applied

When JP1/IM - Manager service is started or auto response action definition file import command (jddupdateaction) is executed, this file is imported and applied to the system.

## Information that is specified

Same as [7.2.4\(1\) Auto Response Action definition Object](#).

## Example definition

Same as [7.2.4\(1\) Auto Response Action definition Object](#).

## ◆ Response action state monitoring definition file (responseactionnotice.conf)

### Format

```
{
  "meta": {
    "version": "version-information",
  },
  "eventnotice": {
    "autoactionevent": "[automatically-notify-response-action-status]",
  }
}
```

```
}  
}
```

## Files

responseactionnotice.conf

responseactionnotice.conf.model (model file of the response action state monitoring definition file)

## Storage directory

In Windows

For a physical host:

*Manager-path*\conf\imdd\responseaction

For a logical host:

*shared-folder*\jplimm\conf\imdd\response action

In UNIX

For a physical host:

/etc/opt/jplimm/conf/imdd/responseaction

For a logical host:

*shared-directory*/jplimm/conf/imdd/responseaction

## Character code

This file should be saved in UTF-8 without being granted BOM (byte order mark).

## Description

A file that defines setup for monitoring execute status for automated response action.

## When the definitions are applied

Turns enable when JP1/IM - Manager starts.

## Information that is specified

The following table lists the members that can be specified:

| Member          | Data type | Description                                                                                                                                                                                                                                                                                                       | Remarks  |
|-----------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| meta            | object    | Setup of the meta-information.                                                                                                                                                                                                                                                                                    | Required |
| version         | string    | Specifies version of response action state monitoring definition file.<br>Specify 1 as the fixed value.                                                                                                                                                                                                           | Required |
| eventnotice     | object    | Setup to notify the event when status is changed.                                                                                                                                                                                                                                                                 | Optional |
| autoactionevent | string[]  | Specifies status for auto response action to be notified when it reaches which status.<br>You can specify one of the following: <ul style="list-style-type: none"><li>• SENDED<br/>Issues a JP1 event when sending request of response action execute to JP1/IM - Manager managing JP1/IM agent control</li></ul> | Optional |

| Member | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Remarks |
|--------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
|        |           | <p>base to run was completed (when response action's status changes to "Execute control sending").</p> <ul style="list-style-type: none"> <li>• <b>RUNNING</b><br/>Issues a JP1 event when sending request of response action execute to JP1/IM agent control base to run was completed (when status of response action is "Queuing").</li> <li>• <b>ENDED</b><br/>Issues a JP1 event when the command Execute in JP1/IM agent control base is completed (when status in response action is "Terminated" or "Forcibly killed" or "Canceled").</li> <li>• <b>ERROR</b><br/>A JP1 event is issued when Status of Response Action becomes an abnormal Status (when status of response action becomes "Fail," "Communication failed," or "Execute failed").</li> </ul> <p>This member can have more than one setup.<br/>The defaults (default value, assuming an error occurs) work with Status that does not have this member setup.</p> |         |

## Example definition

The following is a sample definition for issuing a JP1 event when execute of auto response action terminates or an execution fails.

```
{
  "meta":{
    "version":"1"
  },
  "eventnotice":{
    "autoactionevent":["ENDED", "ERROR"]
  }
}
```

## ◆ User-created definition file list definition file (imdd\_user\_deffile\_list.json)

### Format

- Format of the definition file

```
{
  "filelist":[
    {
      "filename": "filename",
      "filepath": "full-path-of-file",
      "filecategoryID": "category-ID-of-file",
      "filecategoryName": "category-name-of-file",
      "updateaction": "manipulation-for-definition-import"
    }, ...
  ]
}
```

- Format of the model file

```
{
  "filelist":[
    {
      "filename": "",
      "filepath": "",
      "filecategoryID": "",
      "filecategoryName": "",
      "updateaction": ""
    }
  ]
}
```

## Files

imdd\_user\_deffile\_list.json

imdd\_user\_deffile\_list.json.model (model file)

## Storage directory

In Windows

For a physical host:

*Manager-path*\conf\imdd\fileoperation\

For a logical host:

*shared-folder*\jplimm\conf\imdd\fileoperation\

In UNIX

For a physical host:

/etc/opt/jplimm/conf/imdd/fileoperation/

For a logical host:

*shared-directory*/jplimm/conf/imdd/fileoperation/

## Description

A file that defines a user-created file that can be updated or delete with the functions provided by JP1/IM - Manager.

## When the definitions are applied

Reflected when definition file list acquisition API is executed.

## Character code

UTF-8 (If file has a BOM, load it ignoring BOM)

## Information that is specified

| Item name | Optional | Description                                      |
|-----------|----------|--------------------------------------------------|
| filename  | No       | Indicates file name.                             |
| filepath  | Yes      | Destination of file is written in absolute path. |

| Item name        | Optional | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  |          | <p>If file path (absolute path including file name) exceeds 200 characters, it becomes error.</p> <p>If file with the name specified in filename does not exist in the specified file path, it is regarded as an invalid definition.</p> <p>If this setup field is omitted, "<i>manager-path\conf\imdd\user</i>" is assumed. (For logical environments, replace "<i>manager-path</i>" with "<i>shared-folder\jplimm</i>".)</p> |
| filecategoryID   | Yes      | <p>Describes the category ID to be specified when grouping more than one file.</p> <p>A file with the same category ID is considered to belong to the same category.</p> <p>Allowed characters are alphanumeric characters, "-" (hyphen), and "_" (underscore). Up to 32 characters can be specified. Category ID starting with "jpl_" cannot be specified.</p>                                                                |
| filecategoryName | Yes      | <p>Specifies the category name for category ID.</p> <p>Specify a character other than a control character. Up to 32 characters can be specified.</p> <p>If no filecategoryID is specified, this setup field is ignored. If a filecategoryID is specified and this setup field is not specified, filecategoryID's value is setup.</p>                                                                                           |
| updateaction     | Yes      | <p>Describes the action (command-line) that should be executed if file is updated.</p> <p>For detail, see ■<i>Description of updateaction</i>.</p>                                                                                                                                                                                                                                                                             |

## ■Description of updateaction

You can list the commands that Execute after updating file. The maximum length of a command line that can be written is 4,096 bytes.

If execute destination is a 64-bit Windows and you specify commands that are located in the %WINDIR%\System32 folders or lower, be aware of WOW64 redirection function.

Command options cannot be specified. If you specify this option, create a batch file (for Windows) or shell script (for Linux) that specifies the command options, and then specify the batch file or shell script as updateaction.

The following types of commands can execute:

Hosts that execute commands are Windows

- Execution format file (.com, .exe)
- Batch file (.bat)
- The scripting file of JP1/Script (.spt) (but the association must be setup so that .spt file can execute)

Hosts that execute commands are Linux

- Linux commands
- Shell scripts

Note that you cannot execute the following commands:

- Commands that require interaction
- Commands to display the screen
- Commands with escape sequences or control codes
- Commands that do not terminate, such as daemons

- Commands that require interaction with the desktop, such as Windows Message functions and DDE (in Windows)
- Commands that shutdown OS, such as `shutdown` or `halt`

#### ■About files that can be specified for user-created definition file list definition file

File that can be described in user-created definition file list definition file is shown below.

- User-created suggestion definition file (`imdd_suggestion_<any-file-name>.conf`)
- Correlated Event Publishing Definition File
- Correlated event publishing environment-definition File
- Definition file for extended event attributes
- Definition file for extended event attributes (extended file)
- Common exclusion conditions Extended Definition File
- Definition file for opening monitor windows
- User-specific metric definition file (`metrics_<any-Prometheus-trend-name>.conf`)

When `jco_spmc_reload` command is specified in `updateaction` for update of definition file of JP1/IM3 - Manager in logical host environment, `-h` option is not needed.

#### ■About user-created definition file, which output destination is as you want

For the definition file that you create, if files can specify any location as the storage destination, when using the definition file manipulation function, the definition file is stored must be in as follows:

In Windows

For a physical host:

*Manager-path*\conf\imdd\user\

For a logical host:

*shared-folder*\jplimm\conf\imdd\user\

In UNIX

For a physical host:

*/etc/opt/jplimm/conf/imdd/user/*

For a logical host:

*shared-directory*/jplimm/conf/imdd/user/

## Example definition

```
{
  "filelist":[
    {
      "filename": "file_def.conf",
      "filepath": "C:\\Program Files (x86)\\Hitachi\\JP1IMM\\conf\\imdd\\user",
      "filecategoryID": "user_def",
      "filecategoryName": "user_def",
      "updateaction": "JP1Cons\\bin\\jco_spmc_reload.exe"
    }
  ]
}
```

```
]
}
```

## ◆ Definition file properties file (imdd\_file\_properties.json)

### Format

```
{
  "filelist":[
    {
      "filename": "filename",
      "filepath": "full-path-of-file",
      "updateaction": "manipulation-for-definition-import",
      "message": "message"
    }, ...
  ]
}
```

### Files

imdd\_file\_properties.json

### Storage directory

Place the definition file that you want to work with in the get or refresh functions of the definition file into the compressed zip file.

### Description

This file describes file name, file path, and file import operations for the definition file that are to be manipulated by the acquisition or update functions of the definition file.

### When the definitions are applied

None

### Information that is specified

| Item name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| message      | Returns the error message ID and its message body. If it succeeds, omit this item.                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Character code

UTF-8 (If file has a BOM, load it ignoring BOM)

## Example definition

```
{
  "filelist":[
    {
      "filename": "file_def.conf",
      "filepath": "C:\\Program Files (x86)\\Hitachi\\JP1IMM\\conf\\imdd\\user",
      "updateaction": "JP1Cons\\bin\\jco_spmd_reload.exe"
    }
  ]
}
```

## 2.5 JP1/IM - Manager definition files (Central Console)

---

### ◆ Event-source-host mapping definition file (user\_hostmap.conf)

#### Format

```
[DESC_VERSION=version-information]
#Comment
def definition-name-1
    cnd
        event-condition
    end-cnd
    source_attr attribute-name
end-def
def definition-name-2
    cnd
        event-condition
    end-cnd
    source_attr attribute-name
end-def
```

#### File

user\_hostmap.conf (Event-source-host mapping definition file)

user\_hostmap.conf.model (model file for the event-source-host mapping definition file)

#### Storage directory

In Windows

For a physical host:

*Console-path*\conf\hostmap\

For a logical host:

*shared-folder*\jplcons\conf\hostmap\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/hostmap/

For a logical host:

*shared-directory*/jplcons/conf/hostmap/

#### Description

This file defines the conditions and the mapping source for a JP1 event to which the event source host is mapped by using the event source host mapping function. The maximum size of the event-source-host mapping definition file is 17 megabytes.

The event source host mapping function maps the event source host for the JP1 event that matches the event condition according to the definition in this file.

## When the definitions are applied

The definition takes effect when the event source host mapping function is enabled and either of the following conditions is satisfied:

- JP1/IM is running
- The `jco_spmc_reload` command is executed

## Information that is specified

`DESC_VERSION=version-information`

Specify 1, which is the file version of the event-source-host mapping definition file. Specify `DESC_VERSION` on the first line of the definition file (the first line in the file that is not a null line or a comment line). If there is no file version on the first line, 1 is assumed as the file version.

`# comment`

Provides an explanation of the event-source-host mapping definition file.

`def to end-def`

These parameters mark the start and end of the mapping definition block. The block from `def` to `end-def` can be omitted.

After `def` comes the definition name of the event source host mapping definition. If you specify `def Δ Δ Δ definition-1 Δ Δ Δ definition-2 Δ Δ Δ`, then `Δ Δ definition-1 Δ Δ Δ definition-2 Δ Δ Δ` are treated as the definition names (Δ indicates a single-byte space).

Each definition name must be unique within the event-source-host mapping definition file. The length of a character string is from 1 to 50 bytes.

Permitted characters are all characters other than control characters.

The control characters are ASCII 0x00 to 0x1F and 0x7F to 0x9F.

`cnd to end-cnd`

These parameters mark the start and the end of the block that specifies conditions for the JP1 events to be mapped. You must specify one event condition block in a mapping definition block. The event condition block cannot be omitted. If a received JP1 event satisfies multiple event conditions, the definition block closest to the beginning of the event-source-host mapping definition file takes precedence. Tabs and spaces before and after the `cnd` and `end-cnd` parameters are ignored.

*event-condition*

Specifies conditions for the JP1 event to be mapped. You can specify from 1 to 256 event conditions for each event condition block. Event conditions are connected with the AND condition. Specify an event condition in the following format:

*attribute-name comparison-keyword operand*

*attribute-name*

Specifies the name of the attribute you want to compare. To specify a basic attribute, prefix the name with `B..` To specify an extended attribute (common information or user-specific information), prefix the name with `E..` The attribute name is case sensitive.

The following table lists and describes the combinations of attribute names and comparison keywords and the operands that can be specified.

**Table 2–16: Combinations of attribute names and comparison keywords and the operands that can be specified**

| No. | Item                                                 | Attribute name | Comparison keyword                                                                                                                                                                              | Operand                                                                                                                                                              |
|-----|------------------------------------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Event ID                                             | B.ID           | <ul style="list-style-type: none"> <li>• Match</li> <li>• Do not match</li> </ul>                                                                                                               | A maximum of 100 event IDs can be specified. Specify event IDs in hexadecimal notation. Event IDs are not case sensitive. The permitted range is from 0 to 7FFFFFFF. |
| 2   | Reason for registration                              | B.REASON       | <ul style="list-style-type: none"> <li>• Match</li> <li>• Do not match</li> </ul>                                                                                                               | A maximum of 100 reasons can be specified.                                                                                                                           |
| 3   | Source process ID                                    | B.PROCESSID    | <ul style="list-style-type: none"> <li>• Match</li> <li>• Do not match</li> </ul>                                                                                                               | A maximum of 100 source process IDs can be specified. The permitted range is from -2,147,483,648 to 2,147,483,647.                                                   |
| 4   | Source user ID                                       | B.USERID       | <ul style="list-style-type: none"> <li>• Match</li> <li>• Do not match</li> </ul>                                                                                                               | A maximum of 100 source user IDs can be specified. The permitted range is from -2,147,483,648 to 2,147,483,647.                                                      |
| 5   | Source group ID                                      | B.GROUPID      | <ul style="list-style-type: none"> <li>• Match</li> <li>• Do not match</li> </ul>                                                                                                               | A maximum of 100 source group IDs can be specified. The permitted range is from -2,147,483,648 to 2,147,483,647.                                                     |

However, if a regular expression is used, only one product name is allowed.                                                                                                                                                                                                |
| 14  | Object type  | E.OBJECT_TYPE  | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Do not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 object types can be specified. However, if a regular expression is used, only one object type is allowed.                                                                                                                                                                                                  |

| No. | Item             | Attribute name     | Comparison keyword                                                                                                                                                                              | Operand                                                                                                                              |
|-----|------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 15  | Object name      | E.OBJECT_NAME      | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Do not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 object names can be specified. However, if a regular expression is used, only one object name is allowed.           |
| 16  | Root object type | E.ROOT_OBJECT_TYPE | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Do not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 root object types can be specified. However, if a regular expression is used, only one root object type is allowed. |
| 17  | Root object name | E.ROOT_OBJECT_NAME | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Do not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 root object names can be specified. However, if a regular expression is used, only one root object name is allowed. |
| 18  | Object ID        | E.OBJECT_ID        | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Do not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 object IDs can be specified. However, if a regular expression is used, only one object ID is allowed.               |
| 19  | Occurrence       | E.OCCURRENCE       | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Do not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 occurrences can be specified. However, if a regular expression is used, only one occurrence is allowed.             |
| 20  | Return code      | E.RESULT_CODE      | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Do not match</li> <li>• Is contained</li> </ul>                                                           | A maximum of 100 return codes can be specified. However, if a regular expression is used, only one return code is allowed.           |

| No. | Item                                | Attribute name | Comparison keyword                                                                                                                                                                  | Operand                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|-------------------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |                                     |                | <ul style="list-style-type: none"> <li>Is not contained</li> <li>Regular expression</li> </ul>                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                    |
| 21  | Program-specific extended attribute | E.xxxxxxx      | <ul style="list-style-type: none"> <li>First characters</li> <li>Match</li> <li>Do not match</li> <li>Is contained</li> <li>Is not contained</li> <li>Regular expression</li> </ul> | <p>For the attribute name, you can specify a character string with a maximum of 32 bytes that begins with an uppercase letter and consists of uppercase letters, numeric characters, and the underscore (_).</p> <p>A maximum of 100 program-specific extended attributes can be specified. However, if a regular expression is used, only one program-specific extended attribute is allowed.</p> |

#

If the integrated monitoring database and the IM Configuration Management database are enabled, and the comparison keyword is `Match` or `Do not match`, the business group name can be specified in a path format.

If the integrated monitoring database and the IM Configuration Management database are disabled, and a comparison keyword other than `Match` or `Do not match` is selected, a business group name specified in a path format is treated as a host name.

If the `-ignorecasehost` option of the `jcoimdef` command is set to `ON` and a comparison keyword other than `Regular expression` is selected, the character string is no longer case sensitive.

#### *comparison-keyword*

Specifies `BEGIN` (begins with), `IN` (matches), `NOTIN` (does not match), `SUBSTR` (includes), `NOTSUBSTR` (does not include), or `REGEX` (regular expression) as the comparison keyword. The comparison keyword is case sensitive.

#### *operand*

Specifies a character string as the value that is to be compared with the attribute value specified for the comparison keyword. The operand is case sensitive.

If you specify two or more operands, separate them by one or more consecutive spaces or tabs. The `OR` condition is applied to the specified operands. Note that if a regular expression is specified, only one operand is allowed.

If you want a space or a tab as part of an operand, use the format shown in the following table.

| No. | Value to be specified | How to specify |
|-----|-----------------------|----------------|
| 1   | Tab (0x09)            | %09            |
| 2   | Space (0x20)          | %20            |
| 3   | % (0x25)              | %25            |
| 4   | CR (0x0d)             | %0d            |
| 5   | LF (0x0a)             | %0a            |

During maximum value checking of the definition format, %20 and %25 are each treated as a single character. The following shows an example of defining ID matches 100 and 200, which selects multiple operands:

```
B.IDΔINΔ100Δ200
```

Legend: Δ indicates a single-byte space (0x20)

You can specify a maximum of 4,096 bytes of operands per event condition and per event condition block (total length in bytes of all operands that are specified in the event condition block).

#### *source\_attr*

Specifies the attribute value of the mapping source. For `source_attr`, you can specify a value that stores the event source host name. This parameter cannot be omitted. Specify the `source_attr` in the following format:

source\_attr *mapping-source-attribute-value*

You can specify an attribute name or a variable name for the mapping source attribute value. If you specify an attribute name, all information related to the attribute value is stored. If you specify a variable name, part of an attribute value is extracted (partial extraction) and stored.

The attribute you can specify for the mapping source attribute value is an extended attribute (program-specific information). Extended attributes (program-specific information) are attributes that are not included in the common information described in [Table 3-2 List of common information provided by extended attributes](#). You can specify \$EVENV1 to \$EVENV9 for the variable name.

## Example definition

The following example shows how to set the host name (AGENT\_A) contained in a message as the event source host name when the event ID is 100, the event level is Warning, and the message is An error with error code 1111 occurred on the AGENT\_A host. (where AGENT\_A is a host name):

```
DESC_VERSION=1
#Maps the host name in the message to the event source host name.
def event-source-host-mapping-1
  cnd
    B.ID IN 100
    E.SEVERITY IN Warning
    B.MESSAGE REGEX An error occurred on the host ([a-zA-Z0-9\-\_]+) wit
h error code 1111.
  end-cnd
  source_attr $EVENV1
end-def
```

## ◆ Automated action environment definition file (action.conf.update)

### Format

```
[logical-host-name\JP1CONSOLEMANAGER\ACTION]
"ACTIONINFSIZE"=dword:hexadecimal-value
"EVENTALIVEPERIOD"=dword:hexadecimal-value
"ACTIONEXECUSER"="JP1-user-name"
"ACTIONDEFFILE"="file-name"
"HOSTINEVENT"="{remote | local}"
"ACTIONINFFILE"="file-name"
"ACTIONLIMIT"=dword:hexadecimal-value
"SENDABLE_EVENT"="event-ID"
"REGEXP"="{JP1 | EXTENDED}"
"ACTIONPRIORITY"="{DEFAULT | V8COMPATIBLE}"

[logical-host-name\JP1CONSOLEMANAGER\LOG_CONTROL\JCAMAIN]
"LOGSIZE"=dword:hexadecimal-value
```

This is the format of the parameters in the common definition information. Do not edit any other parameters because they are used internally.

### File

action.conf.update (model file for the automated action environment definition file)

## Storage directory

In Windows

*Console-path*\default\

In UNIX

/etc/opt/jplcons/default/

## Description

This file defines an execution environment for automated actions.

The required definitions are provided as a model file. To change the settings, copy the model file and edit the copy after renaming the copy to definition file (for Windows: *console-path*\conf\action.conf, for UNIX: /etc/opt/jplcons/conf/action.conf).

To reduce the size of the action information file

Make a backup of the action information file, delete the action information file, and then change the settings.

## When the definitions are applied

The specified definitions take effect when JP1/IM - Manager starts after you have executed the `jbssetcnf` command to apply the definitions to the JP1 common definition information.

You can also apply the following parameters by reloading them with the `jco_spmc_reload` command:

- EVENTALIVEPERIOD
- ACTIONEXECUSER
- HOSTINEVENT
- SENDABLE\_EVENT

## Information that is specified

[*logical-host-name*\JP1CONSOLEMANAGER\ACTION]

Specifies a key name for the action execution environment settings.

For *logical-host-name*, specify JP1\_DEFAULT for a physical host and *logical-host-name* for a logical host.

"ACTIONINFSIZE"=dword:*hexadecimal-value*

Specifies the size of the action information file as a hexadecimal value (kilobytes).

The permitted value is from dword:00000001 to dword:00001000 (1 to 4,096 kilobytes). The default value is dword:00001000 (4,096 kilobytes).

The action information file stores automated action execution information. The file is referenced when an action is referenced from the event console or by the `jcashowa` command as well as when an action status notification event is issued.

This is a wrap-around file that is overwritten when the specified ACTIONINFSIZE value is reached. Once overwritten, old action information might no longer be viewable in the event console or with the `jcashowa` command and action status notification events might no longer be issued. If you will reference past action execution results or issue action information notification events, you must estimate the size of the action information that you will want to reference and then set that value in ACTIONINFSIZE.

For details about how to estimate the size of the action information file, see the Release Notes for JP1/IM - Manager.

When you set the action information file size to the default value, you can reference information equivalent to 65,535 actions.

"EVENTALLIVEPERIOD"=dword:*hexadecimal-value*

Specifies the AND event storage period in minutes.

The permitted value is from 1 to 1,440 (minutes), expressed as a hexadecimal value. The default is dword:0000003c (60 minutes).

"ACTIONEXECUSER"="JP1-user-name"

Specifies a JP1 user as the default user who executes actions.

Express the JP1 user as a character string of no more than 15 bytes. The default is "" (none). If this parameter is omitted, jpladmin is assumed.

When no execution user is specified in an automated action definition, the action will be executed by the JP1 user defined here.

"ACTIONDEFFILE"="file-name"

Specifies a name for the automated action definition file.

The default is actdef.conf; you cannot change this default value.

Use this automated action definition file to define conditions for executing actions by the automated action function and the commands to be executed.

"HOSTINEVENT"="{remote | local}"

Specifies the method to be used to acquire the host name at the event source.

The permitted values are remote and local. The default is remote.

- When remote is set, the event attribute *event-issuing server name* is used as the event source host name.
- When local is specified, if the source IP address in the event attribute is an IPv6 address in JP1/IM - Manager, the host name found by using getnameinfo is used as the event source host name. If, however, the source IP address is an IPv4 address, the host name found by using gethostbyaddr is used as the event source host name. If the host name cannot be found, the IP address is used as the event source host name.

Note:

If "local" is specified, the action matching might take a longer time due to DNS queries or other reasons.

"ACTIONINFFILE"="file-name"

Specifies a name for the action information file.

The default is actinf.log. You cannot change this default value.

"ACTIONLIMIT"=dword:*hexadecimal-value*

Specifies the number of commands to be pre-loaded.

If you use JP1/Base version 06-51 or earlier at the automated action execution host, specify the number of commands that are to be pre-loaded at the execution host. The permitted value is from dword:00000001 to dword:00000040 (1 to 64). The default is dword:0000000a (10).

If you use JP1/Base version 06-71 or later at the automated action execution host, set the number of pre-loaded commands in JP1/Base at the execution host. In this case, use the jccmddef command at the execution host to set the number of pre-loaded commands. The default is 1,024 commands.

For details, see 14.7.6 *Command execution environment* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

"SENDABLE\_EVENT"="event-ID"

Specifies an automated action issuance event (JP1 event whose event ID is 20A0, 20A1, 20A2, 20A3, or 20A4).

The permitted values are 20A0, 20A1, 20A2, 20A3, and 20A4. To specify multiple event IDs, separate them with the space.

The default is "20A0 20A3 20A4".

For details about the JP1 events, see [3.2.2 Details of JP1 events output by JP1/IM - Manager](#).

"REGEXP"="{ JP1 | EXTENDED } "

Specifies the type of regular expressions to be used.

The permitted values are JP1 and EXTENDED. The default is EXTENDED.

If you specify JP1, you can use JP1-specific regular expressions to define automated actions. If you specify EXTENDED, you can use extended regular expressions to define automated actions.

Note that this parameter is used only for Windows, and is not necessary for UNIX.

"ACTIONPRIORITY"="{ DEFAULT | V8COMPATIBLE } "

Specifies the priority order for actions.

The permitted values are DEFAULT and V8COMPATIBLE. These values are case sensitive.

If this parameter is omitted altogether, V8COMPATIBLE is assumed.

When JP1/IM - Manager is initially installed, DEFAULT is set.

When JP1/IM - Manager is upgraded from version 8 or earlier, the ACTIONPRIORITY parameter is not set.

- If DEFAULT is specified and multiple action definitions are specified for the same parameter, the first action definition specified in the automated action definition file takes effect.
- If V8COMPATIBLE is specified, the same priority order is applied as is used for the automated action function in JP1/IM - Manager versions earlier than 09-00. In other words, if multiple action definitions are specified for the same parameter, an action definition with an event ID specified takes precedence over an action definition for all events, and an action definition with an event ID that is specified closest to the beginning of the automated action definition file takes precedence over all other action definitions with event IDs specified.

[*logical-host-name*\JP1CONSOLEMANAGER\LOG\_CONTROL\JCAMAIN]

Specifies a key name for the automated action log definition.

For *logical-host-name*, specify JP1\_DEFAULT for the physical host and *logical-host-name* for a logical host.

"LOGSIZE"=dword:*hexadecimal-value*

Specifies the maximum size of an automated action trace log (1 file).

The permitted value is from 65,536 to 104,857,600 bytes (64 kilobytes to 100 megabytes), expressed in bytes as a hexadecimal value. The default is dword:00500000 (5,242,880 bytes (5 megabytes)).

The default value will not cause wrap-around in the file even when 300 commands with a maximum length of 100 bytes per command are executed for actions. To change the log size, see the Release Notes for JP1/IM - Manager and then estimate the log size.

## Example definition

```
[JP1_DEFAULT\JP1CONSOLEMANAGER\ACTION]
"ACTIONINFSIZE"=dword:00001000
"EVENTALLIVEPERIOD"=dword:0000003c
"ACTIONEXECUSER"="JP1USER"
"ACTIONDEFFILE"="actdef.conf"
"HOSTINEVENT"="remote"
"ACTIONINFFILE"="actinf.log"
"SENDABLE_EVENT"="20A0 20A3 20A4"
"REGEXP"="JP1"

[JP1_DEFAULT\JP1CONSOLEMANAGER\LOG_CONTROL\JCAMAIN]
"LOGSIZE"=dword:00100000
```

Make sure that the end of the file is at the beginning of the last line.

## ◆ Automated action definition file (actdef.conf)

### Format

```
[#automated-action-definition-file-version]
[DESC_VERSION=version-information]

[#automated-action-status-monitoring-parameter]
cmn
    [sta {true|false}]
end-cmn

[#automated-action-definition-parameter]
act action-name
    [prm parameter-group]
    [cmt comment]
    aid action-ID
    [valid true|false]
    eid event-ID

    cnd
        event-conditions
    end-cnd

    [usr user-name]
    [hst {execution-host-name|group-name|business-group-name|monitoring-group-name}]
    [cmd action]
    [var environment-variable-file-name]

    [det suppress-period]
    [ret delay-monitoring-period]
end-act
```

### File

actdef.conf (automated action definition file)

actdef.conf.model (model file for the automated action definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\action\

For a logical host:

*shared-folder*\jplcons\conf\action\

In UNIX

For a physical host:

`/etc/opt/jplcons/conf/action/`

For a logical host:

`shared-directory/jplcons/conf/action/`

## Description

This file defines conditions for executing actions by the automated action function of JP1/IM and the commands to be executed as the actions. To use the language encoding that is used by JP1/IM - Manager, specify this file.

The maximum size of an automated action definition file is 22 megabytes (23,068,672 bytes).

The automated action function automatically executes a specified command on the basis of the definition specified in this file when a JP1 event satisfying specified conditions is received.

Each line of action definition information is called a *parameter*. There are three types of parameters in an automated action definition file:

- Automated action definition file version  
Defines the format version of the automated action definition file.
- Automated action status monitoring parameter (common block)  
Specify the `cmn` parameter in the common block to define whether the status of automated actions is to be monitored.
- Automated action definition parameters (action block)  
Specify parameters, such as `prm` and `cmt`, in the action block to define conditions for executing an action and the command to be executed as the action.

You must specify the automated action definition file version and the automated action status monitoring parameter before the automated action definition parameters. If you specify the automated action definition file version and/or the automated action status monitoring parameter after the automated action definition parameters, the specified definition is ignored.

If you specify the automated action definition file version or the automated action status monitoring parameter more than once, the first definition specified takes effect and subsequent definitions are ignored.

### Definition specification

- Use the space or the tab to separate the words in a parameter.
- Any space or tab character at the beginning or at the end of a line is ignored.
- A line beginning with hash mark (#) is regarded as a comment except when the hash mark (#) is preceded by a character string.
- Use lowercase letters to specify the parameter names in action definitions. A specified parameter name that contains uppercase letters is treated as being invalid and results in a definition error.

### Action priority

If a received JP1 event satisfies the execution conditions in multiple automated action definitions, only the automated action that has the highest priority is executed (for each parameter group discussed below). The automated action priority order is determined by the following rule:

- The first action specified in the automated action definition file (in GUI, the first action displayed in the Action Parameter Definitions) takes precedence over the other actions.

You can change the action priority order in the common definition. For details about the priority order of automated actions, see 6.3.2 *Precedence of execution conditions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

### *Parameter groups and AND conditions*

Each automated action definition parameter belongs to a *parameter group*. A parameter group is a unit for checking the conditions for executing an automated action. Use of parameter groups enables you to specify complex conditions, such as when multiple actions are to be executed for a single JP1 event or when an action is to be executed only when multiple conditions are satisfied.

When a single JP1 event arrives at the manager host of JP1/IM, the automated action definition parameters and execution conditions are compared for each parameter group in order of priority. When execution conditions that are satisfied are found, only the automated action definition parameter that has the highest priority is executed for each parameter group.

If you specify an ampersand (&) in a parameter group, an AND condition with the automated action definition parameter defined on the preceding line is created. When automated action definition parameters are specified in an AND condition, the corresponding action is executed when all the conditions are satisfied.

### *Checking the specified information*

Use the `jcamakea` command to check the information specified in the definition file.

## **When the definitions are applied**

The definition of an automated action takes effect when you click the **Apply** button in the Action Parameter Definitions window in JP1/IM - View when JP1/IM - Manager starts, or when you execute the `jccache` command.

If you want to execute the `jccache` command to re-load the definition, execute the `jcamakea` command first to make sure there are no errors in the definition.

## **Information that is specified (automated action definition file version)**

This subsection describes the information to be specified as the automated action definition file version.

### *DESC\_VERSION=version-information*

Defines the format version of the automated action definition file. Specify this definition on the first line of the automated action definition file (the first line in the file excluding null lines and comment lines). If this information is specified on a line other than the first line, a definition error results.

**Table 2–17: Automated action definition file format version information**

| Version information | Description                                                 |
|---------------------|-------------------------------------------------------------|
| 1                   | Automated action definition file version is 07-11 to 07-51. |
| 2                   | Automated action definition file version is 08-01 to 08-50. |
| 3                   | Automated action definition file version is 09-00 to 11-10. |
| 4                   | Automated action definition file version is 11-50 or later. |

If this parameter is omitted or 1 is specified, the value 2 is assumed for reading the file. When the **Apply** button is clicked in the Action Parameter Definitions window in JP1/IM - View, the value 2 is set.

If a value other than 1, 2, 3, or 4 is specified in this parameter, an error is output to the integrated trace log and the value 3 is assumed as the version information for reading the file.

In such a case, the Action Parameter Definitions window cannot be displayed in JP1/IM - View. To change the version information, directly edit the definition file.

Because the format of an old automated action definition file version is compatible with the automated action definition file format for version 08-01 or later, the format for version 08-01 or later is assumed for reading the file.

If this parameter is specified on a line that is subsequent to a line containing an automated action definition parameter, the Action Parameter Definitions window can no longer be displayed in JP1/IM - View.

Use the `jcamakea` command to check the contents of the automated action definition file.

## Information that is specified (automated action status monitoring parameter)

This subsection describes the information to be specified in the automated action status monitoring parameter.

`cmn` to `end-cmn`

These are the start and end parameters for the block that specifies a parameter that is applicable to all action definitions. The portion between `cmn` and `end-cmn` is called a common block. This block must be specified before the automated action definition parameters. Specify this parameter only once in the automated action definition file. Specification of this block is optional. If this block is omitted, `false` is assumed for the `sta` parameter. The AND condition is applied to each event condition.

`sta {true|false}`

Specifies whether the action status is to be monitored.

Specify either `true` or `false`. To monitor the action status, specify `true`. To not monitor the action status, specify `false`. The default is `false`.

## Information that is specified (automated action definition parameters)

This subsection describes each item that is specified in the automated action definition parameters.

`act` *action-name* to `end-act`

Specifies the start and end parameters of an automated action definition. There is no limit to the number of actions that can be defined between `act` and `end-act`; however, at least one action must be specified. The portion between `act` *action-name* and `end-act` is called an action block.

After `act`, specify an action name, expressed using from 1 to 50 bytes of characters. The permitted characters are all characters other than the control characters (from `0x00` to `0x1F` and from `0x7F` to `0x9F`).

Each action name must be unique among the action names specified in all the action blocks. The parameters that can be specified in the action block are as follows:

`prm`, `cmt`, `eid`, `cnd` to `end-cnd`, `usr`, `hst`, `cmd`, `var`, `det`, `ret`, `aid`, `valid`

`prm` *parameter-group*

Specifies a number for the parameter group. If this parameter is omitted, 0 is assumed.

You can specify a single numeric digit (from 0 to 9) or the ampersand (&). If you specify a numeric digit, you cannot omit the action name. If you specify an ampersand (&), this parameter becomes part of an AND condition with the immediately preceding action block, which means that the automated action definition parameter in this action block belongs to the same parameter group as the immediately preceding action block. When an ampersand (&) is specified, the action name cannot be specified.

Following an action block for which the ampersand is not specified, you can specify a maximum of 9 action blocks as members of an AND condition (for a total of 10 action blocks including the first action block).

Within the same parameter group, the first action block specified (in the GUI, the top action block displayed in the Action Parameter Definitions window) has precedence over the other action blocks. When a JP1 event arrives at the manager, it is matched against the event conditions in the action block for each parameter group in the order of priority. When event conditions are found that match the JP1 event, the action in the action block that has the highest priority is executed for the parameter group and no more matching is performed for the action blocks that follow the executed action block. Events are matched in ascending order of parameter groups. For details about the priority order of automated actions, see 6.3.2 *Precedence of execution conditions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

`cmt comment`

Specifies a comment about the action block. This parameter is optional. Specify a comment using from 1 to 1,040 bytes of characters. All characters are permitted. If a comment exceeds 1,040 bytes in length, the portion in excess of 1,040 bytes is deleted.

`aid action-id`

Specifies the action ID. This parameter cannot be omitted. The action ID can be any number from 0 to 2,147,483,647. However, this parameter cannot be specified when you have specified `&` for the *parameter-group*.

This parameter can be specified only when the version information is 4.

`valid true|false`

Enables or disables (specifies `true` or `false`, respectively) the automated action definition. This parameter is optional. If this parameter is omitted, the value is assumed to be `true`. However, this parameter cannot be specified when you have specified `&` for the *parameter-group*. When you have specified `&` for the *parameter-group*, the status (enabled or disabled) of the automated action definition depends on the status of the previous action execution condition.

This parameter can be specified only when the version information is 4.

`eid event-ID`

Specifies the event ID for the action conditions. This parameter is mandatory and can be specified only once.

An event ID consists of a base part and an extension part. Express each part of an event ID as a string of from 1 to 8 hexadecimal characters, and separate the base part from the extension part with a colon (:). An event ID is not case sensitive. The extension part can be omitted. To specify any event ID, use an asterisk (\*). When an asterisk is specified, all events become subject to the action. If JP1 events occur frequently, a large number of actions will be implemented, in which case execution may be delayed. When you specify an asterisk, you should narrow down the applicable events by using other conditions (such as a message, basic event information, detailed event information, and extended event information).

The following shows an example:

Example: Specify event ID A as follows:

```
eid a
eid A
eid 0000000a
eid 0000000A
eid 0000000A:0
eid 0000000A:00000000
```

Example: Specify any event ID as follows:

```
eid *
```

`cnd event-conditions to end-cnd`

Specifies the start and end parameters of the block that specifies event conditions for executing an action.

Specification of an event condition block is mandatory. Specify only one event condition block within an action block. You can specify from 0 to 256 event conditions in an event condition block. The AND condition is applied to each event condition.

*event-conditions*

Specifies the event conditions in the following format ( $\Delta$  indicates a single-byte space):

*attribute-name* $\Delta$ *comparison-keyword* $\Delta$ *operand* [*operand*] . . .

Note that a line consisting of only spaces or tabs is ignored during processing.

### *attribute-name*

Specifies the name of an attribute that you want to compare. To specify a basic attribute, place `B .` immediately before the name. To specify an extended attribute (common information or user-specific information), place `E .` immediately before the name. Attribute names are case sensitive.

### *comparison-keyword*

Specifies one of `BEGIN` (begins with), `IN` (matches), `NOTIN` (does not match), `SUBSTR` (includes), `NOTSUBSTR` (does not include), or `REGEX` (regular expression) as the comparison keyword. The comparison keyword is case sensitive.

### *operand*

Specifies a character string as the value that is to be compared with the attribute value by the specified comparison keyword. Operands are case sensitive.

To specify multiple operands, separate them with one or more consecutive spaces or a tab. The `OR` condition is applied to the specified operands. Note that when a regular expression is specified, only one operand can be specified.

To use a space, tab, end-of-line code (CR or LF), or `%` as part of an operand value, you must specify a value shown below:

| No. | Value to be used               | What to specify  |
|-----|--------------------------------|------------------|
| 1   | Tab (0x09)                     | <code>%09</code> |
| 2   | Space (0x20)                   | <code>%20</code> |
| 3   | <code>%</code> (0x25)          | <code>%25</code> |
| 4   | Linefeed code LF (0x0a)        | <code>%0a</code> |
| 5   | Carriage return code CR (0x0d) | <code>%0d</code> |

The character code specified after `%` is not case sensitive. When a JP1 regular expression is used, `%0d` cannot be specified. The following shows an example of defining ID matches 100 and 200, which selects multiple operands:

```
B.IDΔINΔ100Δ200
```

Legend: `Δ` indicates a single-byte space (0x20)

You can specify a maximum of 4,096 bytes of operands per event condition and per event condition block (total length in bytes of all operands that are specified in the event condition block).

### *Basic event information*

If you specify `B . BASIC` as the attribute name, you can set the same conditions as for basic event information in the automated action definition file (for conversion).

When you specify `B . BASIC` as the attribute name, you must specify `REGEX` as the comparison keyword.

You can specify the operands in the same format as is used for basic event information in the automated action definition file (for conversion). Note that to use a space, tab, end-of-line code (CR or LF), or percent sign (`%`), specify `%`. Specify a forward slash (`/`) as `/;`; there is no need to specify it as `\/`.

### *Detailed event information*

If you specify `B . DETAIL` as the attribute name, you can set the same conditions as for detailed event information in the automated action definition file (for conversion).

When you specify `B . DETAIL` as the attribute name, you must specify `REGEX` as the comparison keyword.

You can specify the operands in the same format as is used for detailed event information in the automated action definition file (for conversion). Note that to use a space, tab, end-of-line code (CR or LF), or percent sign (`%`), specify `%`. Specify a forward slash (`/`) as `/;`; there is no need to specify it as `\/`.

The following table lists and describes the attribute names, comparison keywords, and operands that can be specified in an event condition.

**Table 2–18: Attribute names, comparison keywords, and operands that can be specified in an event condition**

| No. | Item              | Attribute name | Comparison keywords                                                                                         | Operand                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----|-------------------|----------------|-------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Event ID          | B.ID           | <ul style="list-style-type: none"> <li>Match</li> <li>Does not match</li> <li>Regular expression</li> </ul> | <p>Specifies an event ID.</p> <ul style="list-style-type: none"> <li>A maximum of 100 event IDs can be specified. | 28  | Program-specific extended attribute | --               | <ul style="list-style-type: none"> <li>Match</li> <li>Does not match</li> <li>Is contained</li> <li>Is not contained</li> <li>First characters</li> <li>Regular expression</li> </ul> | <p>Specifies the attribute name of a program-specific extended attribute.</p> <ul style="list-style-type: none"> <li>You can specify a name with a maximum length of 32 bytes that begins with an uppercase letter and consists of uppercase letters, numeric characters, and the underscore (_).</li> <li>A maximum of 100 extended attribute names can be specified. However, if a regular expression is used, only one extended attribute name is allowed.</li> </ul> |

**Legend:**

--: None

<sup>#</sup>

If the integrated monitoring database and the IM Configuration Management database are enabled, and the comparison keyword is *Match* or *Do not match*, the business group name can be specified in a path format.

If the integrated monitoring database and the IM Configuration Management database are disabled, and a comparison keyword other than *Match* and *Do not match* is selected, a business group name specified in a path format is treated as a host name.

If the `-ignorecasehost` option of the `jcoimdef` command is set to `ON`, and a comparison keyword other than *Regular expression* is selected, the character string is no longer case sensitive.

**usr *user-name***

Specifies the user name of the JP1 user who executes the action. The `usr` parameter is optional. If this parameter is omitted, the system assumes the JP1 user name specified as the default action execution user in the definition of the automated action execution environment. If the default action execution user is also omitted, `jpladmin` is assumed.

The number of characters you can specify is 1 to 31 bytes for the user name. Only one-byte alphanumeric characters can be used. Alphabetic characters are not case sensitive. You can specify a variable for the user name. You specify a variable when you want to set information contained in the received JP1 event as the user name.

You can set event information for the user name.

When the action is executed, the JP1 user specified here is mapped to the OS user at the execution host that will execute the command, according to the JP1/Base definition. In UNIX, the shell environment of the mapped OS user is used for execution.

`hst { execution-host-name | group-name | business-group-name | monitoring-group-name }`

Specifies the name of the host on which an action is executed, a host group name, a business group name, or a monitoring group name. For a host name, specify a name set as a managed host in the system configuration definition. The `hst` parameter is optional. If it is omitted, the local host is assumed.

Express the execution host name or host group name using from 1 to 255 bytes of characters. The execution host name or host group name cannot contain the space character. You can specify a variable for the execution host name or host group name. You specify a variable when you want to set information contained in the received JP1 event as the execution host name or host group name. For example, to execute the action on the host that issues the event, specify `$EVHOST`.

You can set event information for the execution host name or host group name.

For a business group name and monitoring group name, you can specify a character string with a maximum of 2,048 bytes. If the specified character string begins with a slash (/), it is treated as a business group name or a monitoring group name. Note, however, that the character string is treated as a host name or a host group name if the integrated monitoring database and the IM Configuration Management database are disabled.

`cmd action`

Specifies the command that is to be executed as the action. For details about the specifiable commands, see *Chapter 6. Command Execution by Automated Action (JP1/Base linkage)* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

The `cmd` parameter is optional. If this parameter is omitted, no action is taken even when conditions for action execution are satisfied.

Note that if any of the following parameters is omitted, omitting the `cmd` parameter results in a definition error:

`usr, var, hst, det, ret`

The `cmd` parameter cannot be specified more than once. Specify the parameter using from 1 to 4,096 bytes of characters. Any tabs or spaces preceding the action are deleted, but spaces following the action are not deleted.

You can set event information for the action.

You can use a variable to specify information contained in the received JP1 event. For example, if the execution host is UNIX, the following specification sets the name of the host that issued the JP1 event in the `HOSTNAME` environment variable:

```
HOSTNAME="$EVHOST" action
```

```
xxx_BASIC="$EVBASE" xxx_MESSAGE="$EVMSG" action
```

*Notes about the length of an action command*

The maximum length of a command that can be executed as an action is 4,096 bytes including the information obtained after converting variables to be used in the action definition (such as `$EVMSG`). If the command length exceeds 4,096 bytes, the execution status becomes `Fail`, in which case the command is not executed. In such a case, the message `KAVB4421-W` is displayed in the **Message** field in the Action Log Details window.

The length of a command that can be executed as an action also depends on the system where JP1/IM - Manager and JP1/Base are running.

If any of the hosts on the automated action execution route (including the source manager host and target execution host) runs JP1/IM - Manager or JP1/Base version 6 or version 7, the maximum length of a command must not exceed 1,024 bytes. For notes about the length of a command, see *13.4.1 Notes regarding the considerations for automated actions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

*Notes about codes that cannot be recognized as characters in an action*

If codes (ASCII codes and characters not included in the character set of the multi-byte characters encoding specified in the environment settings) that are not recognizable as characters are included in an action, the action might not be executed, or if it is executed, might result in an error because of the shell or other specifications on the execution host. In such a case, the action results in terminated status, not an execution failure. Even though there might be no invalid code in the definition file, an invalid code might be generated when a variable used in the action definition is

replaced with the actual value. For details about the correct specification of variables in an action definition, consult the documentation for the products that issue action-related events.

#### `var environment-variable-file-name`

Specifies the full path name of the environment variable file that specifies environment variables for the command that is to be executed as the action. This parameter is optional. If this parameter is omitted, it is assumed that there is no environment variable file. For details about the format of an environment variable file, see the *JP1/Base User's Guide*.

Express the environment variable file name using from 1 to 255 bytes of characters. You can set event information for the environment variable file name. You can specify a variable for the environment variable file name. You specify a variable when you want to set information contained in the received JP1 event as the environment variable file name. For example, to set the JP1 event extended attribute named `ENVFILE` as the environment variable file name, specify `$EV"ENVFILE"`.

Spaces before and after the environment variable file name are not deleted. Only one tab or one space character following `var` is deleted.

#### `det suppress-period`

Specifies a period during which action execution is to be suppressed. The action for the action conditions is suppressed if it would otherwise occur during the period specified in this parameter. This parameter is optional. If this parameter is omitted, the action is not suppressed. The permitted value range for the suppression period is from 1 to 3,600 (seconds). This parameter cannot be specified when you have specified `&` for the parameter group. In the case of AND conditions, specify the suppression period in the first automated action definition parameter that is defined for the AND conditions.

#### `ret delay-monitoring-period`

Specifies a period during which monitoring for the action execution is performed. If the amount of time specified in this parameter expires before a command control action termination message is received from the execution host after a JP1 event arrived at JP1/Base at the manager, a delay of action is reported by using a method such as JP1 event issuance or command execution. This parameter is optional. If this parameter is omitted, no monitoring for action delay is performed. The permitted value range for the delay monitoring period is from 1 to 86,400 (seconds).

#### `#comment-line`

A line beginning with a hash mark (`#`) is treated as a comment. Note that if you set an action definition from JP1/IM - View, comment lines with the `#` mark are deleted.

## Variables that can be used in the action definition

In a definition of automated action definition parameters, you can use variables in the `usr`, `var`, `hst`, and `cmd` parameters to specify information contained in the JP1 events.

When the action is executed, the variables are replaced with the actual information in the JP1 event.

To specify a variable in an automated action definition parameter, use a format such as `$EVID`. If you want to specify `$` as a character, specify the escape character `\` before the `$`.

The following table lists and describes the available variables.

Table 2–19: Variables that can be used in action definitions

| Type of information                                         | Variable name         | Description                                    |
|-------------------------------------------------------------|-----------------------|------------------------------------------------|
| Information contained in the basic attributes of JP1 events | <code>EVBASE</code>   | Entire basic event information <sup>#1</sup>   |
|                                                             | <code>EVID</code>     | Event ID ( <i>basic-code : extended-code</i> ) |
|                                                             | <code>EVIDBASE</code> | Event ID (basic code)                          |

| Type of information                                            | Variable name               | Description                                                                                                                     |
|----------------------------------------------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------|
|                                                                | EVDATE                      | Event registration date (YYYY/MM/DD) <sup>#2</sup>                                                                              |
|                                                                | EVTIME                      | Event registration time (hh:mm:ss) <sup>#2</sup>                                                                                |
|                                                                | EVPID                       | Event source process ID                                                                                                         |
|                                                                | EVUSRID                     | User ID of the event source process                                                                                             |
|                                                                | EVGRPID                     | Group ID of the event source process                                                                                            |
|                                                                | EVUSR                       | Event source user name                                                                                                          |
|                                                                | EVGRP                       | Event source group name                                                                                                         |
|                                                                | EVHOST                      | Event source host name                                                                                                          |
|                                                                | EVIPADDR                    | Event source IP address                                                                                                         |
|                                                                | EVSEQNO                     | Serial number                                                                                                                   |
|                                                                | EVARVDATE                   | Event arrival date (YYYY/MM/DD) <sup>#2</sup>                                                                                   |
|                                                                | EVARVTIME                   | Event arrival time (hh:mm:ss) <sup>#2</sup>                                                                                     |
|                                                                | EVSRCNO                     | Serial number at the event source                                                                                               |
|                                                                | EVMSG                       | Entire message text <sup>#3</sup>                                                                                               |
|                                                                | EVDETAIL                    | Entire detailed event information <sup>#3, #4</sup>                                                                             |
| Information contained in the extended attributes of JP1 events | EVSEV                       | Severities in extended event information (Emergency, Alert, Critical, Error, Warning, Notice, Information, Debug) <sup>#3</sup> |
|                                                                | EVUSNAM                     | User name <sup>#3</sup>                                                                                                         |
|                                                                | EVOBTYP                     | Object type <sup>#3</sup>                                                                                                       |
|                                                                | EVOBNAM                     | Object name <sup>#3</sup>                                                                                                       |
|                                                                | EVROBTYP                    | Registration type <sup>#3</sup>                                                                                                 |
|                                                                | EVROBNAM                    | Root object name <sup>#3</sup>                                                                                                  |
|                                                                | EV"PRODUCT_NAME"            | Product name <sup>#5</sup>                                                                                                      |
|                                                                | EV"OBJECT_ID"               | Object ID <sup>#5</sup>                                                                                                         |
|                                                                | EV"OCCURRENCE"              | Occurrence <sup>#5</sup>                                                                                                        |
|                                                                | EV"START_TIME"              | Start time <sup>#5</sup>                                                                                                        |
|                                                                | EV"END_TIME"                | End time <sup>#5</sup>                                                                                                          |
|                                                                | EV"RESULT_CODE"             | Return code <sup>#5</sup>                                                                                                       |
|                                                                | EV"JP1_SOURCEHOST"          | Issuing host name <sup>#5</sup>                                                                                                 |
|                                                                | EV"extended-attribute-name" | Any extended attribute <sup>#5</sup>                                                                                            |
| Other                                                          | EV"@JP1IM_CORRELATE"        | Correlation event flag <ul style="list-style-type: none"> <li>Not a correlation event: 0</li> </ul>                             |

| Type of information | Variable name                | Description                                                                                                                                                                                                               |
|---------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     |                              | <ul style="list-style-type: none"> <li>Correlation approval event: 1</li> <li>Correlation failure event: 2</li> </ul>                                                                                                     |
|                     | EV"@JP1IM_ORIGINAL_SEVERITY" | Extended event information original severity level (Emergency, Alert, Critical, Error, Warning, Notice, Information, or Debug) <sup>#3</sup>                                                                              |
|                     | EV"@JP1IM_CHANGE_SEVERITY"   | New severity level flag <ul style="list-style-type: none"> <li>Severity is not changed: 0</li> <li>Severity is changed: 1</li> </ul>                                                                                      |
|                     | EV"@JP1IM_DISPLAY_MESSAGE"   | Changed display message                                                                                                                                                                                                   |
|                     | EV"@JP1IM_CHANGE_MESSAGE"    | Display message change flag <ul style="list-style-type: none"> <li>Message has not been changed: 0</li> <li>Message was changed: 1</li> </ul>                                                                             |
|                     | ACTHOST                      | Manager host name at the action request source <sup>#3</sup>                                                                                                                                                              |
|                     | EVENV1 to EVENV9             | Data obtained by specifying parentheses ( ) in a regular expression in the specification of an action execution condition <sup>#5</sup> (applicable only when an extended regular expression is used at the manager host) |

#1: The basic information of a JP1 event is converted to the following format and passed to the action (Δ indicates a single-byte space):

*event-IDΔevent-source-user-nameΔevent-source-user-IDΔevent-source-group-nameΔevent-source-group-IDΔevent-source-event-server-nameΔevent-source-process-IDΔevent-registration-dateΔevent-registration-timeΔevent-source-host-IP-address*

An item that is not set is replaced with the null character.

#2: Converted in the time zone for JP1/IM - Manager and passed to the action.

#3: When an action is executed, if the applicable attribute does not exist, the variable is converted to a null character and passed to the action.

#4: When detailed attribute information for a JP1 event is in binary format, the variable is converted to a null character and passed to the action.

#5: If the applicable attribute does not exist, the character string of the variable is passed to the action as is.

In addition, depending on the type of JP1 event, an action might not be executed, or if executed, might result in an error because the variable itself does not exist or codes (ASCII codes and characters that are not included in the character set of the multi-byte characters encoding specified in the environment settings) not recognizable as characters are included. See the documentation for the JP1 event source product to check the attribute information, and then set the characters that need to be replaced.

## Encoding for event inheritance information

For **Action** of the action-related items, you can use URL encoding or Base64 encoding for the values for event inheritance information. The specification format is *\$variable-name\$encoding-type*. To specify a single-byte alphanumeric character or an underscore ( \_ ) immediately after *encoding-type*, use the format *{ \$ { variable-name\$encoding-type } }*. If you specify a dollar sign (\$) as part of a character string, immediate before \$, specify \ as an escape character.

In the following cases, *\$variable-name\$encoding-type* and *{ \$ { variable-name\$encoding-type } }* will be treated as character strings and thus will not be converted:

- There is no event that corresponds to *variable-name*.
- The specification format is invalid.

The following table describes the encoding types for event inheritance information and shows the specification formats.

Table 2–20: Encoding types for event inheritance information and specification formats

| No. | Encoding type                         | Specification format                        | Description                                                                                                    |
|-----|---------------------------------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| 1   | URL encoding                          | <code>\$variable-name\$URLENC</code>        | URL encoding is used to encode the value of event inheritance information as a UTF-8 character string.         |
|     |                                       | <code>\${variable-name\$URLENC}</code>      |                                                                                                                |
| 2   | Base64 encoding                       | <code>\$variable-name\$ENC</code>           | Base64 encoding is used to encode the value of event inheritance information.                                  |
|     |                                       | <code>\${variable-name\$ENC}</code>         |                                                                                                                |
| 3   | Both Base64 encoding and URL encoding | <code>\$variable-name\$ENC\$URLENC</code>   | The value of event inheritance information is encoded by using Base64 encoding and then by using URL encoding. |
|     |                                       | <code>\${variable-name\$ENC\$URLENC}</code> |                                                                                                                |
| 4   | No encoding is performed              | <code>\$variable-name</code>                | Neither URL encoding nor Base64 encoding is performed.                                                         |
|     |                                       | <code>\${variable-name}</code>              |                                                                                                                |

### Notes about specifying variables

- If you specify a character, such as an alphanumeric character or an underscore (`_`), immediately after the variable name, the variable will not be converted correctly. In such a case, enclose the variable name in curly brackets (`{ }`), as shown in the examples below. These examples assume that `100:0` is specified as the event ID (`$EVID`) and `ABC` is specified as the extended attribute `EX` (`$EV"EX"`).

Examples:

*action-definition* → *information-after-conversion*

`$EVID abc` → `100:0 abc`

`$EVIDabc` → `$EVIDabc` (in Windows), none (in UNIX)

`${EVID}abc` → `100:0abc`

`$EVID_abc` → `$EVID_abc` (in Windows), none (in UNIX)

`${EVID}_abc` → `100:0_abc`

`$EV"EX" abc` → `ABC abc`

`$EV"EX"abc` → `ABCabc`

- If the source character information contains any of the control characters shown below, the control character is converted to a space (`0x20`).

Control characters that are converted to a space: `0x01` to `0x1F` (excluding tab (`0x09`)), `0x7F`

For example, if the message acquired by specifying `$EVMSG` contains a linefeed code (`0x0A`), the linefeed code (`0x0A`) is converted to the space (`0x20`).

Example: If the action `echo $EVMSG` is set and the character string "*line-1* `0x0A` *line-2*", which contains a linefeed code, is received as the message for the event, the command "`echo line-1line-2`" is executed as the action. (`Δ` indicates a single-byte space.)

- When a backslash (`\`) is specified immediately before a dollar sign (`$`), the dollar sign is treated as a character string. However, if you attempt to specify a backslash followed by a variable, for example, in a file path, the backslash will be converted instead of being treated as a character string. You can prevent this by one of the following methods:

- Using an execution command:

Create a batch file in which the variable is specified for the argument. Use the batch file to specify commands that include backslashes.

Example of how to specify an execution command:

- Execution command: `AppTest.bat $ACTHOST`

- Batch file: `application.exe c:\work\%1\result.txt`

In this example, the conversion result of `$ACTHOST` is set for `%1`.

- Using a variable in a file path:

Add a prefix to the variable.

The following are examples of when `IM-VIEW` is set for `EV"PRODUCT_NAME"`.

Example when the variable cannot be converted:

- Example specification: `C:\$EV"PRODUCT_NAME"`
- Conversion result: `C:$EV"PRODUCT_NAME"`

In this example, `EV"PRODUCT_NAME"` cannot be converted because `\$` is specified.

Example when the variable can be converted:

- Example specification: `C:\pre_$EV"PRODUCT_NAME"`
- Conversion result: `C:\pre_IM-VIEW`

In this example, `EV"PRODUCT_NAME"` can be converted because `pre_` is added before the variable.

- In UNIX, the final expansion depends on the interpretation by the shell. If the expanded data contains a character that has a special meaning in the shell, such as `*`, it is replaced by the corresponding data. To prevent such characters from being converted, enclose the entire variable in double-quotation marks (`"`), such as `"$EVMSG"`.
- If JP1 event information specified by a variable contains a double quotation (`"`), single-quotation mark (`'`), or another character that has a special meaning when used in a command, the command might not be interpreted correctly. We recommend that you convert such characters in the configuration file for converting information. For details about the configuration file for converting information, see [Configuration file for converting information \(event\\_info\\_replace.conf\)](#) in *Chapter 2. Definition Files*.

## Regular expressions in an action definition

This subsection describes how to use regular expressions to specify attributes of JP1 events (message text, basic attributes, and detailed information) in an event monitoring condition of an automated action definition.

The supported regular expressions depend on the OS. The regular expressions supported by Windows and UNIX are described below.

If you share the same action definitions among different OSs, specify conditions using expressions that are supported by all the OSs because interpretation of regular expressions depends on the OS. Regular expressions supported by all OSs are presented in *Appendix G. Regular Expressions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*. Consult this information to determine the regular expressions that can be used.

### *Regular expressions for the Windows version*

For the Windows version, you can set the supported regular expressions to either JP1-specific regular expressions or extended regular expressions. The default is extended regular expressions. For details about how to specify JP1-specific regular expressions, see [Automated action environment definition file \(action.conf.update\)](#) in *Chapter 2. Definition Files*.

### *Regular expressions for the UNIX version*

For the UNIX version, use the extended regular expressions. For details about the supported regular expressions, see the OS-provided *regex(5)*.

### *Notes on regular expressions*

- Because the regular expression of the automated action is a partial match, conditions are the same regardless of whether the same characters (`.` `*`) are specified for the first and last characters.

For example, the same conditions can be set for the following examples 1 and 2:

Example 1: Regular expression matching the string containing "A001Δ:ΔWEB-server":

```
. *A001Δ:ΔWEB-server.*
```

Example 2: Regular expression matching the string containing "A001Δ:ΔWEB-server":

```
A001Δ:ΔWEB-server
```

Do not specify (.\* ) at the beginning or end because searching might take a long time.

- If the `jcamakea` command is executed to check a file that contains either of the regular expressions below, the KAVB5759-W message appears:
  - Regular expression beginning or ending with . \*
  - Regular expression containing successive instances of . \*

For details about the KAVB5759-W message, see the *JP1/Integrated Management 3 - Manager Messages*.

## Example definition

The examples below show example definitions for the automated action definition file. Note that the extended regular expression is specified as the regular expression type in these examples.

### Example definition 1: Using a variable (1)

The following is an example definition for specifying JP1 event information received by using a variable as an argument of a command to be executed as an action:

- Event condition

The event ID (B.ID) is 00000001.

The message format is *message-ID#Δ:Δmessage-text*.

#: A message ID consists of one alphabetic character and three numeric characters.

- Command to be executed as an action

```
alarm.batΔargument-1Δargument-2
```

- JP1 event information to be specified as a command argument

*argument-1*: The message value ({EVMSG} is specified as a variable)

*argument-2*: The extended attribute value AAA ({EV"AAA"} is specified as a variable)

```
1 DESC_VERSION=3

2 cmn
3   staΔfalse
4 end-cmn

5 actΔaction 1
6   prmΔ0
7   cmtΔExample of using a variable
8   eidΔ1

9   cnd
10    B.MESSAGEΔREGEXΔ (^[A-Z][0-9][0-9][0-9])%20:%20(.*)
11   end-cnd

12   cmdΔalarm.batΔ"$EV"AAA""Δ"$ {EVMSG}"
13 end-act
```

Note: In this example, a line number is inserted at the beginning of each line to indicate the individual lines you need to write in the definition file.

When the value for the received JP1 event message (B.MESSAGE) is A001Δ:ΔThe WEB server goes down. and the value for the AAA extended attribute is kanshi, the action `alarm.batΔ"kanshi"Δ"A001Δ:ΔThe WEB server goes down."` is performed.

## Example definition 2: Using a variable (2)

The following is an example definition for specifying a part of the JP1 event information received by using the variables EVENV1 to EVENV9 as arguments of the command to be executed as an action:

- Event condition

The event ID (B.ID) is 00000001.

The message format is *message-ID#Δ:message-text*.

#: A message ID consists of one alphabetic character and three numeric characters.

- Command to be executed as an action

alarm.batΔ*argument-1*Δ*argument-2*

- JP1 event information to be specified as command arguments

*argument-1*: Message ID value ({EVENV1} is specified as a variable)

*argument-2*: Message text value ({EVENV2} is specified as a variable)

```
1 DESC_VERSION=3
2 cmn
3   staΔfalse
4 end-cmn
5 actΔaction 1
6   prmΔ0
7   cmtΔExample of using a variable
8   eidΔ1
9   cnd
10    B.MESSAGEΔREGEXΔ(^[A-Z][0-9][0-9][0-9])%20:%20(.*)
11 end-cnd
12 cmdΔalarm.batΔ"${EVENV1}"Δ"${EVENV2}"
13 end-act
```

Note: In this example, a line number is inserted at the beginning of each line to indicate the individual lines you need to write in the definition file.

When the value for the received JP1 event message (B.MESSAGE) is A001Δ:ΔThe WEB server goes down., the action alarm.batΔ"A001"Δ"The WEB server goes down." is performed.

## Example definition 3: Specifying an event ID in a regular expression (1)

The following is an example definition when B.ID is specified as the attribute name of an event condition and REGEX is specified as the comparison keyword:

- Event condition

The event ID is a value from 00000001 to 00000200 (Hexadecimal A to F not included).

The event-issuing server name (B.SOURCESERVER) is kanshi.

- Command to be executed as an action

alarm.bat

```

1 DESC_VERSION=3

2 cmn
3  sta△false
4 end-cmn

5 act△action 1
6  prm△0
7  cmt△Event ID:00000001 to 00000200
8  eid△*

9  cnd
10   B. ID△REGEX△(^0000000[1-9]|^000000[1-9][0-9]|^000001[0-9][0-9]|^00000200)
11   B. SOURCESERVER△IN△kanshi
12  end-cnd

13  cmd△alarm.bat
14 end-act

```

Note: In this example, a line number is inserted at the beginning of each line to indicate the individual lines you need to write in the definition file.

To specify an event ID as an event condition, specify \* for `eid` so that the event ID specified as an event condition becomes the target.

#### Example definition 4: Specifying an event ID in a regular expression (2)

If `B.BASIC` is specified for the attribute name as an event condition, the conditions can be set in the same format used for the basic event information of the automatic action definition file (for compatibility).

The following is an example definition when `B.BASIC` is specified as the attribute name of an event condition and `REGEX` is specified as the comparison keyword:

- Event condition

The event ID is a value from 00000001 to 00000200 (Hexadecimal A to F not included).

The event-issuing server name (`B.SOURCESERVER`) is `kanshi`.

- Command to be executed as an action

`alarm.bat`

```

1 DESC_VERSION=3

2 cmn
3  sta△false
4 end-cmn

5 act△action1
6  prm△0
7  cmt△Event ID:00000001 to 00000200
8  eid△*

9  cnd
10   B.BASIC△REGEX△(^[1-9]|^[1-9][0-9]|^[1][0-9][0-9]|^200)
      :0%20.%20.%20.%20.%20kanshi%20.%20.%20.%20.%$
11  end-cnd

12  cmd△alarm.bat
13 end-act

```

Note: In this example, a line number is inserted at the beginning of each line to indicate the individual lines you need to write in the definition file. Line10 spans two lines here, but write it as one line in the definition file.

The method for specifying a tab, space, %, or linefeed is different from the method used for the automatic action definition file (for compatibility). For details, see [Automated action definition file \(actdef.conf\) \(for conversion\)](#) in *Chapter 2. Definition Files*.

### Example definition 5: Using the AND condition

The following is an example definition for setting the action to be executed when event A and event B are received:

- Event A conditions

The event ID (B.ID) is 00000201.

The message (B.MESSAGE) is WEB server A goes down..

- Event B conditions

The event ID (B.ID) is 00000202.

The message (B.MESSAGE) is Web server B goes down..

- Command to be executed as an action

alarm.bat

```
1 DESC_VERSION=3
```

```
2 cmn
```

```
3 sta△false
```

```
4 end-cmn
```

```
5 act△action 1
```

```
6 prm△0
```

```
7 cmt△Example of using AND condition (Event A conditions)
```

```
8 eid△201
```

```
9 cnd
```

```
10 B.MESSAGE△IN△WEB server A goes down.
```

```
11 end-cnd
```

```
12 cmd△alarm.bat
```

```
13 end-act
```

```
14 act
```

```
15 prm△&
```

```
16 cmt△Example of using AND condition (Event B conditions)
```

```
17 eid△202
```

```
18 cnd
```

```
19 B.MESSAGE△IN△WEB server B goes down.
```

```
20 end-cnd
```

```
21 end-act
```

Note: In this example, a line number is inserted at the beginning of each line to indicate the individual lines you need to write in the definition file.

When the AND condition is applied, we recommend using an automated action by using the correlation event generation function. The correlation event generation function can specify the sequence or the number of JP1 events, a property not available to the AND condition. For details about correlation events, see *4.3 Issue of correlation events* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## ◆ Automated action definition file (actdef.conf) (for conversion)

### Format

## File

actdef.conf (automated action definition file) (for conversion)

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\action\

For a logical host:

*shared-folder*\jplcons\conf\action\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/action/

For a logical host:

*shared-directory*/jplcons/conf/action/

## Description

This file defines (for conversion) conditions for executing actions by the automated action function of JP1/IM and the commands to be executed as the actions. Use the language encoding that is used by JP1/IM - Manager to specify this file.

When a JP1 event satisfying specified conditions is received, the automated action function executes automatically a specified command based on the definition specified in this file.

Each line of action definition information is called a *parameter*. There are three types of parameters in an automated action definition file:

- Automated action definition file version  
Defines the format version of the automated action definition file.
- Automated action status monitoring parameter  
Defines whether the status of automated actions is to be monitored.
- Automated action definition parameters  
Define conditions for executing an action and the command to be executed as the action.

You must specify the automated action definition file version and the automated action status monitoring parameter before the automated action definition parameters. If you specify the automated action definition file version and/or the

automated action status monitoring parameter after any automated action definition parameters, the specified definition is ignored.

If you specify the automated action definition file version or the automated action status monitoring parameter more than once, the first definition specified takes effect and subsequent definitions are ignored.

### *Definition specification*

The automated action status monitoring parameter and the automated action definition parameters specify one definition per line. A definition that will not fit on one line can be continued onto the next line.

An automated action definition parameter is specified in the format *event-monitoring-condition : action-execution-definition*, consisting of two components separated by a colon (:).

- The maximum length of one automated action definition parameter is 5,706 bytes.  
Spaces are counted, but the \ in a linefeed code or in a continuation line indicator is not counted.
- An automated action definition parameter that will not fit on one line can continue onto the next line.  
To continue a definition onto the next line, specify \ immediately before the linefeed code at the end of the line. If there is any character, including a space, between \ and the linefeed code, the \ will be regarded as data.
- A line containing a hash mark (#) in column 1 is regarded as a comment line.  
A comment must be specified on a single line. If a comment consists of multiple lines, all but the first line will be discarded when the GUI is used for specifying the definition. Any hash marks (#) in columns other than column 1 or on continuation lines are treated as data, not as a comment.

### *Priority order of event monitoring conditions*

If a received JP1 event satisfies the execution conditions in multiple automated action definitions, only the automated action that has the highest priority level is executed (for each parameter group discussed below). The automated action priority order is determined by the following rules:

- For automated actions with an event ID specified, an automated action that is applied to all event IDs takes precedence.
- The first action specified in the automated action definition file (in GUI, the first action displayed in the Action Parameter Definitions) takes precedence.

### *Parameter groups and AND conditions*

Each automated action definition parameter belongs to a parameter group. A parameter group is a unit for checking the conditions for executing an automated action. Use of parameter groups allows you to specify complex conditions, such as when multiple actions are to be executed for a single JP1 event or when an action is to be executed only when multiple conditions are satisfied.

When a single JP1 event arrives at the manager of JP1/IM, the automated action definition parameters and execution conditions are compared for each parameter group in order of priority. When execution conditions that are satisfied are found, only the automated action definition parameter that has the highest priority is executed for each parameter group.

If you specify an ampersand (&) in a parameter group, an AND condition with the automated action definition parameter defined on the preceding line is created. When automated action definition parameters are specified in an AND condition, the corresponding action is executed when all the conditions are satisfied.

### *Checking the size of an automated action definition parameter*

The following lists the items whose size is checked and the respective maximum sizes:

- The maximum size of an automated action definition parameter is 5,706 bytes.
- In an automated action definition parameter, the maximum size of the event monitoring conditions is 1,040 bytes.
- In an automated action definition parameter, the maximum size of an action is 4,096 bytes.

If a maximum size is exceeded, a message is displayed when the definition is applied and the corresponding automated action definition parameter is ignored.

### *Checking the specified information*

Use the `jcamakea` command to check the information specified in the definition file.

Note that, for the automated action definition file (`actdef.conf`) (for compatibility), a business group name cannot be used. If a business group name is specified, it is treated as a host name.

## **When the definitions are applied**

The definition of an automated action takes effect when you click the **Apply** button in the Action Parameter Definitions window in JP1/IM - View when JP1/IM - Manager starts, or when you execute the `jccache` command.

If you want to execute the `jccache` command to re-load the definition, execute the `jcamakea` command first to make sure there are no errors in the definition.

## **Information that is specified (automated action definition file version)**

This subsection describes the information to be specified as the automated action definition file version.

`DESC_VERSION=version-information`

Defines the format version of the automated action definition file.

**Table 2–21: Automated action definition file format version information**

| Version information | Description                                                 |
|---------------------|-------------------------------------------------------------|
| 1                   | Automated action definition file version is 07-11 to 07-51. |
| 2                   | Automated action definition file version is 08-01 or later. |
| 3                   | Automated action definition file version is 09-00 or later. |
| 4                   | Automated action definition file version is 11-50 or later. |

If this parameter is omitted or 1 is specified, the value 2 is assumed for reading the file. When the **Apply** button is clicked in the Action Parameter Definitions window in JP1/IM - View, the value 2 is set.

If a value other than 1, 2, 3, or 4 is specified in this parameter, an error is output to the integrated trace log, and the value 3 is assumed as the version information for reading the file. In such cases, the Action Parameter Definitions window cannot be displayed in JP1/IM - View. To change the version information, edit the definition file.

Because the format of an old automated action definition file version is compatible with the automated action definition file format for version 08-01 or later, the format for version 08-01 or later is assumed for reading the file.

If this parameter is specified on a line that is subsequent to a line containing an automated action definition parameter, the Action Parameter Definitions window can no longer be displayed in JP1/IM - View.

Use the `jcamakea` command to check the contents of the automated action definition file.

## **Information that is specified (automated action status monitoring parameter)**

This subsection describes the information to be specified in the automated action status monitoring parameter.

```
state_watch={true | false}
```

Specifies whether the action status is to be monitored.

Specify either `true` or `false`. The default is `false`.

If `true` is specified, the Action Parameter Definitions window cannot be displayed in JP1/IM - View version 07-01 or earlier.

This parameter is effective only if it is specified before the automated action definition parameters.

If this parameter is specified on a line that is subsequent to a line containing an automated action definition parameter, the Action Parameter Definitions window can no longer be displayed in JP1/IM - View.

You should use the `jcamakea` command to check the contents of the automated action definition file.

When JP1/IM - View version 07-11 or later is connected to JP1/IM - Manager (Central Console) version 07-11 or later, the automated action status monitoring parameter will always be output to the automated action definition file even when the action status is not being monitored.

## Information that is specified (automated action definition parameters)

This subsection describes each item that is specified in the automated action definition parameters. For details about the JP1 events, see [Chapter 3. JP1 Events](#). Regular expressions and variables that can be specified in the definition are described later.

### *Event monitoring conditions*

The items to be specified as the execution conditions in an automated action definition parameter are described below. The maximum length of a parameter that can be defined as execution conditions is 1,040 bytes.

{ *+parameter-group-number* | & }

Specifies the parameter group number to which the automated action definition parameter on this line belongs, expressed as a single-digit number (from 0 to 9) preceded by a plus sign (+). If this information is omitted, 0 is assumed.

If you specify an ampersand (&), this parameter becomes part of an AND condition with the immediately preceding definition line, which means that the automated action definition parameter on this line belongs to the same parameter group as the parameter on the immediately preceding line.

Note that the parameter group number has nothing to do with the priority order for checking execution conditions or the sequence of executing actions.

### *\$event-ID*

Specifies the event ID preceded by the dollar sign (\$). The specification format of an event ID is as follows:

*basic-part* [ *:extended-part* ]

Specify the basic and extended parts each using from 1 to 8 hexadecimal numbers (from 0 to 7FFFFFFF). Alphabetic characters must be specified as lowercase letters.

\*

Specifies that the target is all event IDs. When an asterisk (\*) is specified, all events become subject to the action. If JP1 events occur frequently, a large number of actions will be implemented, in which case execution may be delayed. When you specify an asterisk, you should narrow down the applicable events by using other conditions (such as a message, basic event information, detailed event information, and extended event information).

### *message*

Specifies as an execution condition a message text associated with the JP1 event. You can use a regular expression for the condition. When you use a regular expression, specify the message text without control codes.

To express / in a regular expression, specify \/.

### *basic-event-information*

Specifies information about JP1 event basic attributes that are to be used as an execution condition. You can use a regular expression to specify this information.

To express / in a regular expression, specify \/. For details about regular expressions, see *Appendix G. Regular Expressions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

The basic event information is passed as information about JP1 event basic attributes in the format shown below. Use this format to specify a condition for executing an action.

*event-ID*Δ*event-source-user-name*Δ*event-source-user-ID*Δ

*event-source-group-name*Δ*event-source-group-ID*Δ

*event-issuing-server-name*Δ*event-source-process-ID*Δ

*event-registration-year-month-day*Δ*event-registration-time*Δ*event-source-host-IP-address*

For details about the information included in the JP1 event basic attributes, see *Chapter 3. JP1 Events*.

### *detailed-event-information*

Specifies information about detailed attributes in the JP1 event basic attributes that is to be used as an execution condition.

You can use a regular expression to specify this information.

To express / in a regular expression, specify \/. For details about regular expressions, see *Appendix G. Regular Expressions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

The detailed attributes in the JP1 event basic attributes consist of additional JP1 event information. The details and format of this information depend on the JP1 event. If the detailed attribute information is specified in binary format, it is treated as no information (NULL).

Remarks: The detailed attributes in the JP1 event basic attributes are used principally to record detailed information provided by products that issue events that are compatible with the JP1/SES format of version 5 or earlier. Most products whose version is 6 or later use the JP1 event extended attributes to record detailed information.

### *event-levels-of-extended-event-information*

Specifies the severity levels in the extended attributes of the JP1 events that are to be set as an execution condition. Specify the event levels (severities) by combining the applicable characters in the following format:

-----E Event level:Emergency

-----A- Event level:Alert

-----C-- Event level:Critical

----E--- Event level>Error

---W---- Event level:Warning

--N----- Event level:Notice

-I----- Event level:Information

D----- Event level:Debug

For example, to set as a condition all severities at the Error and higher event levels, specify /----ECAE/.

### *attribute-name-of-extended-event-information=/attribute-value/*

Specifies a combined name and value of the JP1 event extended attribute used to form an execution condition. You can use a regular expression to specify this information.

To express / in a regular expression, specify \/.

You can specify a maximum of 100 pairs of attribute name and attribute value combinations.

For an attribute name, you can specify from 1 to 32 bytes of uppercase letters, numeric characters, and the underscore (\_). The attribute name cannot contain a colon (:) or an equal sign (=). Specify an attribute name in a form such as PRODUCT\_NAME or OBJECT\_NAME. Unlike the settings in other functions, this attribute name is not prefixed with E..

If you specify an event level in this item (item name `SEVERITY`), specify the attribute value as a character string, such as `Emergency` or `Alert`.

### *Action execution definition*

The following describes the items in an automated action definition parameter that can be used to specify an action execution definition.

`u=user-name`

Specifies the user name of the JP1 user who executes the action.

You can specify 1 to 31 bytes of characters. Only one-byte alphanumeric characters can be used. Alphabetic characters are not case sensitive.

If this parameter is omitted, the system assumes the JP1 user name specified as the default action execution user in the definition of the automated action execution environment. If the default action execution user is also omitted, `jpladmin` is assumed.

You can use a variable to specify information contained in the received JP1 event as the JP1 user name.

When the action is executed, the JP1 user specified here is mapped to the OS user at the execution host that will execute the command, according to the JP1/Base definition. In UNIX, the shell environment of the mapped OS user is used for execution.

`e=environment-variable-file-name`

Specifies the full path name of the environment variable file that specifies environment variables for the command that is to be executed as the action.

The file name can be a character string with a maximum size of 255 bytes. If the file name contains a space, enclose the entire name in double-quotation marks (" ").

You can use a variable to specify information contained in the received JP1 event as the file name. For example, to set the JP1 event extended attribute named `ENVFILE` as the environment variable file name, specify `$EV"ENVFILE"`.

For details about the format of the environment variable file, see the *JP1/Base User's Guide*.

`d=execution-host-name | group-name`

Specifies the name of the host or host group that is to execute the action. For a host name, specify a name set as a managed host in the system configuration definition. A host name or host group name cannot contain a space.

If this parameter is omitted, the action is executed at the local host (the host that contains the automated action definition file).

You can use a variable to specify information contained in the received JP1 event as the host name or group name. For example, to execute the action on the host that issued the event, specify `$EVHOST`.

`dt=suppress-period`

Specifies a period during which action execution is to be suppressed. The action for the action conditions is suppressed if it would occur during the period specified in this parameter. If this parameter is omitted, the action is not suppressed. Express the suppression period using from 1 to 4 bytes of numeric characters. The permitted value range is from 1 to 3,600 (seconds).

When this parameter is specified, JP1/IM - View version 07-01 or earlier cannot display the Action Parameter Definitions window.

Note that this parameter cannot be specified in the following case:

& is specified.

`rt=delay-monitoring-period`

Specifies a period during which monitoring for the action execution is performed. If the amount of time specified in this parameter expires before a command control action termination message is received from the execution host after a JP1 event arrived at JP1/Base at the manager, a delay of action is reported by using a method such as

JP1 event issuance or command execution. This parameter is optional. If this parameter is omitted, no monitoring for action delay is performed.

Express the delay monitoring period using a maximum of five bytes of numeric characters. The permitted value range for the delay monitoring period is from 1 to 86,400 (seconds).

When this parameter is specified, JP1/IM - View version 07-01 or earlier cannot display the Action Parameter Definitions window.

#### *action*

Specifies the command that is to be executed as the action.

For details about the specifiable commands, see *Chapter 6. Command Execution by Automated Action (JP1/Base linkage)* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

If this parameter is omitted, no action is taken even when conditions for action execution are satisfied.

You can use a variable to specify information contained in the received JP1 event as the command parameter.

If the host where the automated action is defined is UNIX, you can use a variable to specify information contained in the received JP1 event as the command environment variable. For example, `MESSAGE="$EVMSG" command arg1 arg2` can be specified.

Note that the colon (:) in the automated action definition parameter is followed by the action to be executed. If you simply specify `u=`, `e=`, `d=`, `dt=`, or `rt=`, it is treated as being part of the previous information, such as a user name. If you specify information such as `u=` and omit the action, an error will result.

The maximum length of a command that can be executed as an action is 4,096 bytes, including the information obtained after converting variables to be used in the action definition (such as `$EVMSG`). If the command length exceeds 4,096 bytes, the execution status becomes `Fail`, in which case the command is not executed. In such a case, the message `KAVB4421-W` is displayed in the **Message** field in the Action Log Details window.

If codes (ASCII codes and characters not included in the character set of the multi-byte characters encoding specified in the environment settings) that are not recognizable as characters are included in an action, the action might not be executed or, if it is executed, might result in an error because of the shell or other specifications on the execution host. If an action contains a code that cannot be recognized as a character, the action might not be executed by the shell at the execution host or might result in an error when the action attempts to execute. In such a case, the action results in terminated status, not an execution failure. Even though there might be no invalid code in the definition file, an invalid code might be generated when a variable used in the action definition is replaced with the actual value. For details about the correct specification of variables in an action definition, consult the documentation for the products that issue action-related events.

#### *Notes about the length of an action command*

The maximum length of a command that can be executed as an action depends on the system where JP1/IM - Manager and JP1/Base are running.

If any of the hosts on the automated action execution route (including the source manager host and target execution host) runs JP1/IM - Manager or JP1/Base version 6 or version 7, the maximum length of a command must not exceed 1,024 bytes. For notes about the length of a command, see *13.4.1 Notes regarding the considerations for automated actions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## **Variables that can be used in the action definition**

In a definition of automated action definition parameters, you can use variables in the specification of the action to be executed (specification following a colon (:)) to set information contained in the JP1 event. When the action is executed, the variables are replaced with the actual information in the JP1 event.

To specify a variable in an automated action definition parameter, use a format such as `$EVID`.

The following table lists the describes the available variables.

Table 2–22: Variables that can be used in the action definition

| Type of information                                            | Variable name                        | Description                                                                                                                                                                                                           |
|----------------------------------------------------------------|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Information contained in the basic attributes of JP1 events    | EVBASE                               | Entire basic event information                                                                                                                                                                                        |
|                                                                | EVID                                 | Event ID ( <i>basic-code : extended-code</i> )                                                                                                                                                                        |
|                                                                | EVDATE                               | Event generation date ( <i>YYYY/MM/DD</i> )                                                                                                                                                                           |
|                                                                | EVTIME                               | Event generation time ( <i>hh:mm:ss</i> )                                                                                                                                                                             |
|                                                                | EVPID                                | Event source process ID                                                                                                                                                                                               |
|                                                                | EVUSRID                              | User ID of the event source process                                                                                                                                                                                   |
|                                                                | EVGRPID                              | Group ID of the event source process                                                                                                                                                                                  |
|                                                                | EVUSR                                | Event source user name                                                                                                                                                                                                |
|                                                                | EVGRP                                | Event source group name                                                                                                                                                                                               |
|                                                                | EVHOST                               | Event source host name                                                                                                                                                                                                |
|                                                                | EVIPADDR                             | Event source IP address                                                                                                                                                                                               |
|                                                                | EVSEQNO                              | Serial number                                                                                                                                                                                                         |
|                                                                | EVARVDATE                            | Event arrival date ( <i>YYYY/MM/DD</i> )                                                                                                                                                                              |
|                                                                | EVARVTIME                            | Event arrival time ( <i>hh:mm:ss</i> )                                                                                                                                                                                |
|                                                                | EVSRCNO                              | Serial number at the event source                                                                                                                                                                                     |
|                                                                | EVMSG                                | Entire message text                                                                                                                                                                                                   |
|                                                                | EVDETAIL                             | Entire detailed event information                                                                                                                                                                                     |
| Information contained in the extended attributes of JP1 events | EVSEV                                | Severities in extended event information (Emergency, Alert, Critical, Error, Warning, Notice, Information, Debug)                                                                                                     |
|                                                                | EV" <i>extended-attribute-name</i> " | Any extended attribute                                                                                                                                                                                                |
| Other                                                          | ACTHOST                              | Manager host name at the action request source                                                                                                                                                                        |
|                                                                | EVENV1 to EVENV9                     | Data obtained by specifying parentheses ( <i>()</i> ) in a regular expression in the specification of an action execution condition (applicable only when an extended regular expression is used at the manager host) |

The value of the variable for an invalid item is NULL. In addition, depending on the type of JP1 event, an action might not be executed, or if executed, might result in an error because the variable itself does not exist or codes (ASCII codes and characters not included in the character set of the multi-byte characters encoding specified in the environment settings) that are not recognizable as characters are included. Consult the documentation for the products that issue JP1 events beforehand for correct specification of the information.

#### Notes about specifying variables

- If you specify a character, such as an alphanumeric character or an underscore (`_`), immediately after the variable name, the variable will not be converted correctly. In such a case, enclose the variable name in curly brackets (`{ }`), as shown in the examples below. These examples assume that `100:0` is specified as the event ID (`$EVID`) and `ABC` is specified as the extended attribute `EX` (`$EV"EX"`).

Examples:

*action-definition* → *information-after-conversion*

```

$EVID abc → 100:0 abc
$EVIDabc → $EVIDabc (in Windows), none (in UNIX)
${EVID}abc → 100:0abc
$EVID_abc → $EVID_abc (in Windows), none (in UNIX)
${EVID}_abc → 100:0_abc
$EV"EX" abc → ABC abc
$EV"EX"abc → ABCabc

```

- If the source character information contains any of the control characters shown below, the control character is converted to a space (0x20).

Control characters that are converted to a space: 0x01 to 0x1F (excluding tab (0x09)), 0x7F

For example, if the message acquired by specifying \$EVMSG contains a linefeed code (0x0A), the linefeed code (0x0A) is converted to the space (0x20).

Example: If the action `echo $EVMSG` is set and the character string "*line-1* 0x0A *line-2*", which contains a linefeed code, is received as the message for the event, the command "`echo line-1Δline-2`" is executed as the action (Δ indicates a space).

- In UNIX, the final expansion depends on the interpretation by the shell. If the expanded data contains a character that has a special meaning in the shell, such as \*, it is replaced by the corresponding data. To prevent such characters from being converted, enclose the entire variable in double-quotation marks ("), such as "EVMSG".
- If a JP1 event specified by using a variable contains a double quotation ("), single-quotation mark ('), or another character that has a special meaning when used in a command, the command might not be interrupted correctly. We recommend that you convert such characters in the configuration file for converting information. For details about configuration file for converting information, see [Configuration file for converting information \(event\\_info\\_replace.conf\)](#) in Chapter 2. Definition Files.

## Regular expressions in the action definition

This subsection describes how to use regular expressions to specify the attributes of JP1 events (message text, basic attributes, and detailed information) in an event monitoring condition of an automated action definition.

The supported regular expressions depend on the OS. The regular expressions supported by Windows and UNIX are described below.

If you share the same action definitions among different OSs, specify conditions using expressions that are supported by all the OSs because interpretation of regular expressions depends on the OS. Regular expressions supported by all OSs are presented in *Appendix G. Regular Expressions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*. Consult this information to determine the regular expressions that can be used.

### *Regular expressions for the Windows version*

For the Windows version, you can set the supported regular expressions to either JP1-specific regular expressions or extended regular expressions. The default is extended regular expressions. For details about how to use the JP1-specific regular expressions, see [Automated action environment definition file \(action.conf.update\)](#) in Chapter 2. Definition Files.

In the case of automated actions in JP1/IM, you can also use the extended notations shown below, in addition to the OS's regular expressions:

`\/, \\\`

Even in an expression enclosed in brackets, / and \ are treated as characters. This method is used to specify / and \ in regular expressions.

## Regular expressions for the UNIX version

For the UNIX version, use the extended regular expressions. For details about the supported regular expressions, see the OS-provided *regex(5)*.

In the case of automated actions in JP1/IM, you can also use the extended notations shown below, in addition to the OS's regular expressions:

`\/, \\`

Even in an expression enclosed in brackets, `/` and `\` are treated as characters. This method is used to specify `/` and `\` in regular expressions.

## Specifying the basic and detailed attributes using regular expressions

This subsection describes how to use regular expressions to specify basic attributes and detailed information about JP1 events in the event monitoring conditions.

The basic attributes of a JP1 event are expressed in the automated action definition parameters in the following format:

*event-ID*<sup>#1</sup> $\Delta$ *event-source-user-name* $\Delta$ *event-source-user-ID* $\Delta$

*event-source-group-name* $\Delta$ *event-source-group-ID* $\Delta$

*event-issuing-server-name*<sup>#2</sup> $\Delta$ *event-source-process-ID* $\Delta$

*event-registration-year-month-day*<sup>#3</sup> $\Delta$ *event-registration-time*<sup>#4</sup> $\Delta$ *event-source-host-IP-address*

#1

The event ID is expressed in the format *basic-code* : *extended-code*. The basic code and extended code are each an 8-digit hexadecimal number (characters from A to F must be uppercase). Any leading zeros in the ID are omitted. If the extended code is 00000000, the event ID is expressed as *basic-code* : 0.

#2

In the event that the server name differs from the host name and the method for acquiring the event issuing host name is set to `local`, the host name is used, not the event server name.

#3

Expressed in the format *YYYY/MM/DD*.

#4

The event registration time is expressed in the format *hh:mm:ss*.

The detailed information about a JP1 event is expressed in the following format:

*information-1* $\Delta$ *information-2* $\Delta$ *information-3* $\Delta$  . . .  $\Delta$ *information-n* $\Delta$

Note:

Depending on the program, the detailed information might not be in this format or it might contain codes that cannot be recognized as characters, such as when only one byte of a multi-byte character is included because of fixed-length requirements. For details about the format, see the documentation for each program.

For both basic attributes and detailed information, each item in the information is separated by a space.

When there is no corresponding information, the item is treated as NULL and multiple consecutive delimiter spaces are displayed. Note that in the future more information might be added after the last item due to functionality extensions.

How to specify each item in the basic attributes and the detailed information is described below.

When you specify the first item in the basic attributes and detailed information, use a caret (^) to indicate the start of a character string. For example, the following specifies the JP1 event whose event ID is 00003A80:

```
^3A80
```

In specifying the second and subsequent items, use .\* (indicating any character string or space) to skip each unneeded item. For example, to specify the event issuing host name, which is the 6th item in the basic event attributes, repeat .\* five times, as follows:

```
^.*Δ.*Δ.*Δ.*Δ.*Δhost01
```

The following are examples of specifying event information:

Example 1: JP1 event sent from the user whose user name begins with JP1USER:

```
^.*ΔJP1USER[_A-Z0-9]+Δ.*Δ.*Δ.*Δ.*Δ.*Δ.*Δ.*Δ.*$
```

Example 2: JP1 event issued at host01 to host05 (when an extended regular expression is used):

```
^.*Δ.*Δ.*Δ.*Δ.*Δhost0[1-5]Δ.*Δhost0[1-5]Δ.*Δhost0[1-5]Δ.*Δhost0[1-5]Δ.*$
```

Example 3: JP1 event registered from 08:00 to 08:10 at host02 (when an extended regular expression is used):

```
^.*Δ.*Δ.*Δ.*Δ.*Δhost02Δ.*Δ.*Δ08:(10|0[0-9]).*Δ.*$
```

Example 4: JP1 event whose third item begins with prn in the detailed information:

```
^.*Δ.*Δprn.*$
```

Note: For the format of detailed information, see the documentation of the program that issues the JP1 events.

#### *Notes about regular expressions*

- To use extended regular expressions by extending JP1-specific regular expressions (Windows), you must re-evaluate the existing definition settings and redefine them for extended regular expressions in order to avoid any malfunction that might be caused by the extension.

The handling of control codes (such as linefeeds and tabs) might vary depending on the product and OS. If you use a regular expression to specify a message as a condition, specify only the message text without the control codes.

- Because the regular expression of the automated action is a partial match, conditions when the same characters (.\* ) are specified as the first and the last characters and when they are not specified are the same.

For example, the same conditions can be set for the following examples 1 and 2:

Example 1: Regular expression matching the string containing "A001Δ:ΔWEB-server":

```
.*A001Δ:ΔWEB-server.*
```

Example 2: Regular expression matching the string containing "A001Δ:ΔWEB-server":

```
A001Δ:ΔWEB-server
```

Do not specify (.\* ) at the beginning or end because searching might take a long time.

- The vertical bar |, which is a special character, represents the OR condition. When you use this OR condition in regular expressions, note the following:

Because the vertical bar | indicating an OR condition has a low priority level, you must explicitly specify the range of the OR condition. Omitting the range might result in no operation or a malfunction. To specify the range of an OR condition, enclose it in parentheses ( ). The example below specifies an OR condition for the event-issuing server name.

Example: JP1 event issued at gyomu or host:

```
^.*Δ.*Δ.*Δ.*Δ.*Δ(gyomu|host)Δ.*Δ.*Δ.*Δ.*$
```

## Example definition

The examples below show example definitions for the automated action definition file. Note that the extended regular expression is specified as the regular expression type in these examples.

### Example definition 1: Using a variable (1)

The following is an example definition for specifying JP1 event information received by using a variable as an argument of a command to be executed as an action:

- Event condition

The event ID (B.ID) is 00000001.

The message format is *message-ID#Δ:Δmessage-text*.

#: A message ID consists of one alphabetic character and three numeric characters.

- Command to be executed as an action

`alarm.batΔargument-1Δargument-2`

- JP1 event information to be specified as a command argument

*argument-1*: The message value (`{EVMSG}`) is specified as a variable)

*argument-2*: The extended attribute AAA (`{EV"AAA"}`) is specified as a variable)

```
1 DESC_VERSION=2
2 :state_watch=false
3 #Example of using a variable
4 +0Δ$1Δ/([A-Z][0-9][0-9])Δ:Δ(.*)/, , Δ:alarm.batΔ"$EV"AAA""Δ"$ {EVMSG}"
```

Note: In this example, a line number is inserted at the beginning of each line to indicate the individual lines you need to write in the definition file.

When the value for the received JP1 event message (B.MESSAGE) is `A001Δ:ΔThe WEB server goes down.`, and the value for the AAA extended attribute is `kanshi`, the action, `alarm.batΔ"kanshi"Δ"A001Δ:ΔThe WEB server goes down."` is performed.

### Example definition 2: Using a variable (2)

The following is an example definition for specifying a part of the JP1 event information received by using the variables EVENV1 to EVENV9 as arguments of the command to be executed as an action:

- Event condition

The event ID (B.ID) is 00000001.

The message format is *message-ID#Δ:Δmessage-text*.

#: A message ID consists of one alphabetic character and three numeric characters.

- Command to be executed as an action

`alarm.batΔargument-1Δargument-2`

- JP1 event information to be specified as a command argument

*argument-1*: Message ID value (`{EVENV1}`) is specified as a variable)

*argument-2*: Message text value (`{EVENV2}`) is specified as a variable)

```
1 DESC_VERSION=2
2 :state_watch=false
3 #Using a variable
4 +0Δ$1Δ/([A-Z][0-9][0-9])Δ:Δ(.*)/, , Δ:alarm.batΔ"${EVENV1}"Δ"${EVENV2}"
```

Note: In this example, a line number is inserted at the beginning of each line to indicate the individual lines you need to write in the definition file.

When the value for the received JP1 event message (B.MESSAGE) is A001Δ:ΔThe WEB server goes down., the action, alarm.batΔ"A001"Δ"The WEB server goes down." is performed.

#### Example definition 3: Specifying an event ID in a regular expression

The following is an example definition when REGEX is specified as the comparison keyword and B.ID is specified as the attribute name of an event condition:

- Event condition

The event ID is a value from 00000001 to 00000200 (Hexadecimal A to F not included).

The event-issuing server name (B.SOURCESERVER) is kanshi.

- Command to be executed as an action

alarm.bat

```
1 DESC_VERSION=2
2 :state_watch=false
3 #The event ID is a value from 00000001 to 00000200 (Hexadecimal A to F not included).
4 +0Δ*Δ,/^([1-9]|^[1-9][0-9]|^[0-9]
  [0-9]|^200):0Δ.*Δ.*Δ.*Δ.*ΔkanshiΔ.*Δ.*Δ.*Δ.*$/,,Δ:alarm.bat
```

Note: In this example, a line number is inserted at the beginning of each line to indicate the individual lines you need to write in the definition file.  
Line 4 spans two lines here, but write it as one line in the definition file.

To specify an event ID in event basic information, specify \* for eid so that the event ID specified in event basic information is to be the target.

In addition, specify a hexadecimal value with a maximum of eight bytes for the basic section and the extended section of an event ID and separate the sections by a colon (:).

#### Example definition 4: Using the AND condition

The following is an example definition for setting the action to be executed when event A and event B are received:

- Event A conditions

The event ID (B.ID) is 00000201.

The message (B.MESSAGE) is WEB server A goes down..

- Event B conditions

The event ID (B.ID) is 00000202.

The message (B.MESSAGE) is Web server B goes down..

- Command to be executed as an action

alarm.bat

```
1 DESC_VERSION=2
2 :state_watch=false
3 #Using the AND condition(Event A conditions)
4 +0Δ$201Δ/WEB server A goes down./,,Δ:alarm.bat
5 #Using the AND condition(Event B conditions)
6 &Δ$202Δ/WEB server B goes down./,,Δ:
```

Note: In this example, a line number is inserted at the beginning of each line to indicate the individual lines you need to write in the definition file.

When the AND condition is applied, we recommend using an automated action by using the correlation event generation function. The correlation event generation function can specify the sequence or the number of JP1 events, a property not available to the AND condition. For details about the correlation events, see *4.3 Issue of correlation events* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## ◆ Automatic action notification definition file (actnotice.conf)

### Format

```
[STATE_WATCH]
EVENT={true | false}
COMMAND=command
[End]
[DELAY_WATCH]
EVENT={true | false}
COMMAND=command
[End]
```

### File

actnotice.conf (automatic action notification definition file)

actnotice.conf.model (model file for the automatic action notification definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\action\

For a logical host:

*shared-folder*\jplcons\conf\action\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/action/

For a logical host:

*shared-directory*/jplcons/conf/action/

### Description

This file defines whether a notification is to be issued when automated action status monitoring or delay monitoring detects an error in an automated action. The notification can be to issue a JP1 event or to execute a notification command. Specify this file by using the language encoding that is used by JP1/IM - Manager.

When you specify in this definition file that notification is to be performed in the event of an automated action error, you will be able to detect an automated action that terminates abnormally in `Fail`, `Error`, or `Fail (Miss)` status by monitoring the automated action status. In such a case, you can specify that a JP1 event is to be issued or that a notification command is to be executed to prompt the operator to take appropriate action for the erroneous automated action. The automated action delay monitoring function enables you to detect an automated action that does not terminate within a specified amount of time (the delay monitoring period) and to issue a JP1 event or execute a notification command to prompt the operator to take appropriate action for the automated action that is in delayed status.

If you have deleted the automatic action notification definition file (actnotice.conf), copy the model file for automatic action notification definition file (actnotice.conf.model) under the name actnotice.conf and change the definitions as necessary.

## When the definitions are applied

The settings in the automatic action notification definition file take effect at the following times

- When JP1/IM - Manager starts
- When the file is reloaded by the `jco_spmc_reload` command

## Information that is specified

### [STATE\_WATCH]

Defines whether to provide notification about an automated action error that is detected during automated action status monitoring by issuing a JP1 event or executing a notification command.

EVENT={true | false}

Specifies whether a JP1 event (event ID: 2011) is to be issued when an error is detected during automated action status monitoring.

Specify either `true` or `false`. If you want to issue a JP1 event when an error is detected, specify `true`; otherwise, specify `false`. The default is `true`. When `true` is specified, a JP1 event (event ID: 2016 or 2021) is also issued in the following cases:

Suppression of notification to the action status monitoring function is released (JP1 event with event ID 2016 is issued).

An erroneous action wraps around in the action information file during action status monitoring (JP1 event with event ID 2021 is issued).

For details about the JP1 events, see [3.2.2 Details of JP1 events output by JP1/IM - Manager](#).

COMMAND=*command*

Specifies the notification command that is to be executed when an error is detected during automated action status monitoring.

You can execute the following types of commands:

When the host executing the command is Windows:

- Executable file (`.com`, `.exe`)
- Batch file (`.bat`)
- JP1/Script script file (`.spt`)

(An appropriate association must have been set so that an `.spt` file can be executed.)

When the host executing the command is UNIX:

- Executable file (with execution permissions)
- Shell script (with execution permissions)
- If neither of the above applies or there is no definition, the default value `unspecified` is assumed.

The following notes apply to defining a notification command:

- Everything from `COMMAND=` to the linefeed code is defined as a single command.
- The maximum length of a command is 1,023 bytes.

If the character string obtained by expanding variables exceeds 1,023 bytes, the command will not execute.

In such a case, the message KAVB4409-E is output to the integrated trace log.

- The maximum length in bytes includes spaces, but does not include the linefeed code.
- If you specify a variable, specify it immediately after `$`. For details about the variables that can be specified, see [Table 2-23 Variables that can be specified in the automatic action notification definition file](#).

The notification command specified in `COMMAND` inherits the execution environment of JP1/IM - Manager.

- The notification command is executed with the execution permissions of JP1/IM - Manager (Windows: SYSTEM user; UNIX: root).
- Specify in `COMMAND` the full path of the notification command.
- Specify for a notification command a command that will always terminate. If you set a batch file (Windows) or a shell script (UNIX), make sure that it will terminate with `exit 0`. If the specified command does not terminate or uses the GUI, processes of the executed notification command will remain unresolved.
- To use \$, specify \$\$.

#### [DELAY\_WATCH]

Defines whether an automated action error that is detected during automated action delay monitoring is to be notified by issuing a JP1 event or by executing a notification command.

`EVENT={true | false}`

Specifies whether a JP1 event (event ID: 2010) is to be issued when an error is detected during automated action delay monitoring.

Specify either `true` or `false`. If you wish to issue a JP1 event when an error is detected, specify `true`; otherwise, specify `false`. The default is `true`. When `true` is specified, a JP1 event (event ID: 2015 or 2020) is also issued in the following cases:

- Suppression of notification to the action delay monitoring function is released (JP1 event with event ID 2015 is issued).
- The erroneous action wraps around in the action information file during action delay monitoring (JP1 event with event ID 2020 is issued).

For details about the JP1 events, see [3.2.2 Details of JP1 events output by JP1/IM - Manager](#).

`COMMAND=command`

Specifies the notification command that is to be executed when an error is detected during automated action delay monitoring.

You can execute the following types of commands:

When the host executing the command is Windows:

- Executable file (.com, .exe)
- Batch file (.bat)
- JP1/Script script file (.spt)

(An appropriate association must have been set so that an .spt file can be executed.)

When the host executing the command is UNIX:

- Executable file (with execution permissions)
- Shell script (with execution permissions)
- If neither of the above applies or there is no definition, the default value `unspecified` is assumed.

The following notes apply to defining the notification command:

- Everything from `COMMAND=` to the linefeed code is defined as a single command.
- The maximum length of a command is 1,023 bytes.

If the character string obtained by expanding variables exceeds 1,023 bytes, the command will not execute.

In such a case, the message KAVB4409-E is output to the integrated trace log.

- The maximum length in bytes includes spaces, but does not include the linefeed code.
- If you specify a variable, specify it immediately after \$. For details about the variables that can be specified, see [Table 2-23 Variables that can be specified in the automatic action notification definition file](#).

The notification command specified in `COMMAND` inherits the execution environment of JP1/IM - Manager.

- The notification command is executed with the execution permissions of JP1/IM - Manager (Windows: SYSTEM user; UNIX: root).

- Specify in `COMMAND` the full path of the notification command.
- Specify for a notification command a command that will always terminate. If you set a batch file (Windows) or a shell script (UNIX), make sure that it will terminate with `exit 0`. If the specified command does not terminate or uses the GUI, processes of the executed notification command will remain unresolved.
- To use \$, specify \$\$.

Table 2–23: Variables that can be specified in the automatic action notification definition file

| Variable name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Example definition

This example issues a JP1 event and executes the notification command `statenotice01.exe` (for status monitoring) or `delaynotice01.exe` (for delay monitoring) when an error is detected during status monitoring or delay monitoring of automated actions:

```
[STATE_WATCH]
EVENT=true
COMMAND=C:\Command\statenotice01.exe
[End]
[DELAY_WATCH]
EVENT=true
COMMAND=C:\Command\delaynotice01.exe

## ◆ Extended startup process definition file (jp1co\_service.conf)

### Format

```
process-name|startup-options|whether-restartable|restart-count|retry-interval|restart-count-reset-time|
```

### File

jp1co\_service.conf (extended startup process definition file)

jp1co\_service.conf.model (model file for the extended startup process definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\

For a logical host:

*shared-folder*\jp1cons\conf\

In UNIX

For a physical host:

/etc/opt/jp1cons/conf/

For a logical host:

*shared-directory*/jp1cons/conf/

### Description

This file defines process information for the functions that constitute JP1/IM - Manager.

JP1/IM - Manager uses the process management function to control restart in the event of abnormal termination of a process. The process management function controls processes according to the definition in the extended startup process definition file.

Do not specify in this file any unneeded characters, such as spaces. Edit numeric values for only those parameters on which editing is permitted.

Customize only the applicable parameters as appropriate to your operations. Normally, there is no need to change the settings for other parameters because appropriate values have already been set in them as the default values for each process.

In the case of a cluster configuration, if the extended startup process definition file is not found in the `conf` folder for the logical host when the a process management process is started at the logical host, the extended startup process definition file for the physical host is copied.

### When the definitions are applied

The contents of the definition file take effect when JP1/IM - Manager starts or when the `jp1co_spmd_reload` command is executed to reload the definition. A change in the *startup-options* parameter takes effect only when JP1/IM - Manager starts.

## Information that is specified

### *process-name*

Specifies the name of a process that is to be started and terminated by the process management function of JP1/IM - Manager.

JP1/IM - Manager's process name is already specified, and must not be edited.

However, if you upgraded from JP1/IM - Manager version 11 or earlier, add `jddmain`, `imbase`, `imbaseproxy` process-definition.

When upgrading from version 12, add `imbase`, `imbaseproxy` process-definition.

The name specified here must be a process name displayed by the `jco_spmc_status` command.

### *startup-options*

Specifies startup options for the process.

#### `-Xmx`

The `-xmx` parameter is a parameter that sets the maximum size of the Java heap space.

The size of the heap area used by the `evtcon` process and the `jddmain` process might exceed the initial value, depending on user settings. The `evtcon` process defaults to `-Xmx 512m`, with a default size of 512 megabytes. The `jddmain` process has no default specification, and the default size is 8,192 megabytes.

If the estimated heap area size that is required exceeds default value, you must change the `-Xmx` parameter's value to a value after a estimation.

For details about how to estimate the heap area size, see the Release Notes for JP1/IM - Manager.

### *Notes about startup options*

- If you change the heap area size for the `evtcon` process of JP1/IM - Manager, check by performing appropriate tests that the change will not cause problems. Even if the value is within the permissible range for the heap area size, a memory shortage might occur and JP1/IM - Manager might terminate or information might not be updated in the Event Console window, resulting in unstable operation. If this occurs, revise as necessary the **Event buffer** and **Num. of events to acquire in 1 search** settings by referencing the formula for estimating the heap area size.
- The maximum memory size cited in the Release Notes for JP1/IM - Manager is a logical value. It might not be possible to allocate the set heap area depending on the OS, the environment in use, and the applications that run concurrently. If the heap area cannot be allocated or the set value is less than default value, problems might occur, such as a JP1/IM - Manager startup error.

The following example changes the heap area size of the `evtcon` process from 512 to 1,024 megabytes in Windows:

Example:

Before the heap area size is changed to 1,024 megabytes (from an initial size of 512 megabytes):

```
evtcon | -Xmx512m | 0 | 3 | 3 | 3600 |
```

After the heap area size has been changed to 1,024 megabytes:

```
evtcon | -Xmx1024m | 0 | 3 | 3 | 3600 |
```

### *whether-restartable*

Specifies whether the process is to be restarted if it terminates abnormally.

Specify 0 to not restart the process and 1 to restart the process.

The default is 0.

### *restart-count*

Specifies the number of times process restart is to be attempted.

The permitted value range is from 0 to 99. The default is 3.

Note that if 0 is specified in the *whether-restartable* field, this field is ignored even if a value is specified.

### *retry-interval*

Specifies in seconds the interval between process restart attempts.

The permitted value range is from 0 to 3,600. The default is 3.

Note that if 0 is specified in the *whether-restartable* field, this field is ignored even if a value is specified.

### *restart-count-reset-time*

Specifies in seconds the amount of time that is to elapse before the restart count will be reset after the process has restarted.

The permitted value range is from 3,600 to 2,147,483,647 (seconds). The default is 3,600.

The restart count is reset when the specified amount of time has elapsed after the process has restarted. If the process terminates abnormally again after this amount of time has elapsed, the restart count starts again from 1. If the process terminates abnormally again within the specified amount of time after it has restarted, the previous restart count is inherited.

Note that if 0 is specified in the *whether-restartable* field, this field is ignored even if a value is specified.

## Example definition

The following shows an example of an extended startup process definition file:

```
evflow||0|3|3|3600|
jcamain||0|3|3|3600|
evtcon|-Xmx512m|0|3|3|3600|
evgen||0|3|3|3600|
jcsmain||0|3|3|3600|
jcfmain||0|3|3|3600|
jddmain||0|3|3|3600|
imbase||0|3|3|3600|
imbaseproxy||0|3|3|3600|
```

## ◆ IM parameter definition file (jp1co\_param\_V7.conf)

### Format

```
[logical-host-name\JP1CONSOLEMANAGER]
"SEND_PROCESS_TERMINATED_ABNORMALLY_EVENT"=dword:value
"SEND_PROCESS_RESTART_EVENT"=dword:value
```

### File

jp1co\_param\_V7.conf (IM parameter definition file)

jp1co\_param\_V7.conf.model (model file for the IM parameter definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\

For a logical host:

*shared-folder\jplcons\conf\*

In UNIX

For a physical host:

*/etc/opt/jplcons/conf/*

For a logical host:

*shared-directory/jplcons/conf/*

## Description

This file defines whether a JP1 event is to be issued when JP1/IM - Manager processes fail or when JP1/IM - Manager processes are recovered automatically from abnormal termination. The following lists the JP1/IM - Manager processes and the JP1 events that can be issued.

- JP1/IM - Manager processes
  - Event Console Service (evtcon)
  - Event Base Service (evflow)
  - Automatic Action Service (jcamain)
  - Central Scope Service (jcsmain)
  - Event Generation Service (evgen)
- JP1 events that can be issued
  - JP1 event whose event ID is 3F90: This event can be issued when a process terminates abnormally.
  - JP1 event whose event ID is 3F91: This event can be issued when a timeout occurs during process startup.
  - JP1 event whose event ID is 3F92: This event can be issued when a process that terminated abnormally has successfully completed restart processing.

By issuing a JP1 event when a process recovers automatically from a process error or abnormal termination, you can manage the history of JP1/IM - Manager failures. For this reason, we recommend that you use this definition file to set issuance of such JP1 events.

The required definitions are provided as a model file. To change the settings, copy the model file and then edit the copy.

## When the definitions are applied

The contents of the file take effect when JP1/IM - Manager is restarted by execution of the `jbssetcnf` command with this definition file specified in an argument.

## Information that is specified

[*logical-host-name*\JP1CONSOLEMANAGER]

Specifies the key name for the JP1/IM - Manager environment settings.

For *logical-host-name*, specify JP1\_DEFAULT for the physical host and *logical-host-name* for a logical host.

"SEND\_PROCESS\_TERMINATED\_ABNORMALLY\_EVENT"=dword:*value*

When 1 is set in *value*, a JP1 event is issued in the following cases:

- A process terminates abnormally (JP1 event whose event ID is 3F90 is issued).

- A timeout occurs during startup processing without a startup notification (JP1 event whose event ID is 3F91 is issued).

The default is 0, in which case no JP1 event is issued.

For details about the JP1 events, see [3.2.2 Details of JP1 events output by JP1/IM - Manager](#).

"SEND\_PROCESS\_RESTART\_EVENT"=dword:*value*

When 1 is set in *value*, a JP1 event is issued in the following case:

- Restart processing of a process that terminated abnormally is completed successfully (JP1 event whose event ID is 3F92 is issued).

The default is 0, in which case no JP1 event is issued.

For details about the JP1 events, see [3.2.2 Details of JP1 events output by JP1/IM - Manager](#).

## Example definition

```
[JP1_DEFAULT\JP1CONSOLEMANAGER]
"SEND_PROCESS_TERMINATED_ABNORMALLY_EVENT"=dword:0
"SEND_PROCESS_RESTART_EVENT"=dword:0
```

Make sure that the end of the file is at the beginning of the last line.

## ◆ System profile (.system)

### Format

```
DESC_VERSION=15
:
[ServerDefine]
InvalidateTime = 1440
EventCount = event-buffer-count
Debug = true
[End]
:
[RetryInfo]
RetryCount = retry-count
RetryInterval = retry-interval
[End]
```

### File

.system (system profile)

.system.model (model file for the system profile)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\profile\

For a logical host:

*shared-folder\jplcons\conf\console\profile\*

In UNIX

For a physical host:

*/etc/opt/jplcons/conf/console/profile/*

For a logical host:

*shared-directory/jplcons/conf/console/profile/*

## Description

This file defines the basic operation of the event console.

There is a system profile for each manager (JP1/IM - Manager). The file defines information about the system environment for the event console (such as the number of event buffers and a retry count for connecting to the event service during event search). The information defined in this profile affects all instances of JP1/IM - View that are connected to the manager to which this profile is applicable.

## When the definitions are applied

The definition takes effect when JP1/IM - Manager starts or when the **Apply** button is clicked in the System Environment Settings window.

## Information that is specified

`EventCount = event-buffer-count`

Specifies the maximum number of events that can be buffered at the manager when events are extracted from the event service.

The permitted value range is from 10 to 2,000. The default is 2,000.

`RetryCount = retry-count`

Specifies the maximum number of times automatic connection establishment can be retried after connection with the event service has failed or the connection has been lost during event search.

The permitted value range is from 0 to 100. The default is 3.

`RetryInterval = retry-interval`

Specifies in milliseconds the retry interval between attempts to establish connection after connection with the event service has failed or the connection has been lost during event search.

The permitted value range is from 1 to 86,400,000. The default is 10,000.

## Notes

- Specify the settings in the System Environment Settings window, unless otherwise necessary.
- Be attentive to the values that you set because the contents of the system profile affect all event console operations. Do not change any attribute or attribute value that is not explained here. If such an attribute or attribute value is changed, the event console might not function correctly.
- You must terminate JP1/IM - View before you edit the system profile.
- There is one system profile for each manager. Therefore, if you have changed the manager for logging in, you must change the system profile at the connection destinations.
- When you intend to edit the contents of the `.system` file, we recommend that you make a backup before editing the file.

- If the system profile contains an error, such as an attribute value that is outside the permitted range of values, the event console might not function correctly.

## Example definition

```
DESC_VERSION=15
:
[End]
[ServerDefine]
InvalidateTime = 1440
EventCount = 500
Debug = true
[End]
:
[RetryInfo]
RetryCount = 3
RetryInterval = 10000
[End]
[LocaleInformation]
Language=English
[End]
```

## ◆ User profile (defaultUser | profile\_user-name)

### Format

```
DESC_VERSION=file-version
[DisplayItemContainer]#
:
[DisplayItemInformation]
ValidTab=All
Visible=whether-visible
AttrName=JP1-event-attribute-name
AttrOrder=sort-order
ColumnSize=column-width
[End]
[End]
:
```

#: You can edit only placeholders in *italic* placed in a section that is enclosed with [DisplayItemInformation] and [End] and that includes ValidTab=All.

### File

defaultUser (default user profile)

defaultUser.model (model file for the default user profile)

profile\_user-name (user profile for an individual JP1 user)

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\profile\

For a logical host:

*shared-folder*\jplcons\conf\console\profile\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/console/profile/

For a logical host:

*shared-directory*/jplcons/conf/console/profile/

## Description

This file defines environment information about how the Event Console window is displayed for each user.

At the manager, there is a user profile for each user. A user profile defines a user environment for the event console (principally, environment information about the window display). A user profile can be created for each user under the name `profile_user-name` (using the JP1 user's user name). There is also a default profile, `defaultUser`, that can be used as the default profile for any user. If you edit the `defaultUser` profile, the new contents become the default profile for user profiles that are created in the future.

You can define `profile_user-name` in the Preferences window. If there are any errors in the user profile, the Event Console window might not display correctly. For this reason, we recommend that you use the Preferences window of JP1/IM - View to define user profiles.

## When the definitions are applied

The definition takes effect the next time you log in to JP1/IM - Manager (Central Console).

## Information that is specified

`DESC_VERSION=file-version`

Specifies the version of the user profile being created. The items that can be specified in `[DisplayItemInformation]` to `[End]` depend on the value specified for the file version. For program version 11-00 or later, specify 15 as the file version. If the file version specified is 11 or earlier, do not attempt to change the file version.

The following operations update all instances of `profile_user-name` to the most recent file version:

- Saving the Preferences window from JP1/IM - View
- Saving the column width of the items that are displayed in the list of events on a page in the Event Console window during logout from JP1/IM - View

To set `defaultUser` (default user profile) to file version 12, overwrite `defaultUser` with `defaultUser.model` (model file for the default user profile), and then edit the file.

`[DisplayItemInformation]` to `[End]`

Specify the attributes of JP1 events that are to be displayed in the Event Console window.

[DisplayItemInformation] through [End] constitute a single definition block. The contents of this definition block take effect on all three pages of the Event Console window. To add a definition block, insert it between [DisplayItemContainer] and [End].

The parameters that can be specified in [DisplayItemInformation] through [End] are described below. You must not edit the parameters in [DisplayItemInformation] through [End] for a definition block in which AttrOrder=0 is specified, because such definition blocks are used by the system.

ValidTab = All

This is a fixed character string that must not be changed.

Visible = *whether-visible*

Specifies whether the information for the attribute specified in AttrName is to be displayed. If true is specified in *whether-visible*, information about the attribute specified in AttrName is displayed. If false is specified, information about the attribute specified in AttrName is not displayed. When false is specified, the corresponding item is displayed in **Available items** in the Preferences window. If you specify false, you must specify -1 in AttrOrder.

AttrName = *attribute-name-to-be-displayed*

Specifies the attribute name of the JP1 event. Information about the attribute specified here is displayed in the Event Console window.

The following table lists the attributes that can be set.

Table 2–24: List of attributes that can be set in attribute-name-to-be-displayed

| No. | Specifiable attribute name | Attribute            | DESC_VERSION |    |       |    |
|-----|----------------------------|----------------------|--------------|----|-------|----|
|     |                            |                      | 1-10#1       | 11 | 12-14 | 15 |
| 1   | IM.EVENT_TYPE              | Type                 | Y            | Y  | Y     | Y  |
| 2   | B.SEQNO                    | Serial number        | Y            | Y  | Y     | Y  |
| 3   | B.IDBASE                   | Event ID             | Y            | Y  | Y     | Y  |
| 4   | B.PROCESSID                | Source process ID    | Y            | Y  | Y     | Y  |
| 5   | B.TIME                     | Registered time      | Y            | Y  | Y     | Y  |
| 6   | B.ARRIVEDTIME              | Arrived time         | Y            | Y  | Y     | Y  |
| 7   | B.USERID                   | Source user ID       | Y            | Y  | Y     | Y  |
| 8   | B.GROUPID                  | Source group ID      | Y            | Y  | Y     | Y  |
| 9   | B.USERNAME                 | Source user name     | Y            | Y  | Y     | Y  |
| 10  | B.GROUPNAME                | Source group name    | Y            | Y  | Y     | Y  |
| 11  | B.SOURCESERVER             | Source host          | Y            | Y  | Y     | Y  |
| 12  | B.SOURCESEQNO              | Source serial number | Y            | Y  | Y     | Y  |
| 13  | B.MESSAGE                  | Message              | Y            | Y  | Y     | Y  |
| 14  | E.SEVERITY                 | Event level          | Y            | Y  | Y     | Y  |
| 15  | E.USER_NAME                | User name            | Y            | Y  | Y     | Y  |
| 16  | E.PRODUCT_NAME             | Product name         | Y            | Y  | Y     | Y  |
| 17  | E.OBJECT_TYPE              | Object type          | Y            | Y  | Y     | Y  |
| 18  | E.OBJECT_NAME              | Object name          | Y            | Y  | Y     | Y  |

| No. | Specifiable attribute name    | Attribute                           | DESC_VERSION       |    |       |    |
|-----|-------------------------------|-------------------------------------|--------------------|----|-------|----|
|     |                               |                                     | 1-10 <sup>#1</sup> | 11 | 12-14 | 15 |
| 19  | E.OBJECT_ID                   | Object ID                           | Y                  | Y  | Y     | Y  |
| 20  | E.ROOT_OBJECT_TYPE            | Root object type                    | Y                  | Y  | Y     | Y  |
| 21  | E.ROOT_OBJECT_NAME            | Root object name                    | Y                  | Y  | Y     | Y  |
| 22  | E.OCCURRENCE                  | Occurrence                          | Y                  | Y  | Y     | Y  |
| 23  | E.START_TIME                  | Start time                          | Y                  | Y  | Y     | Y  |
| 24  | E.END_TIME                    | End time                            | Y                  | Y  | Y     | Y  |

| 33  | E.JP1_SOURCEHOST              | Event source host name              | N                  | N  | Y     | Y  |
| 34  | E.ACTION_TARGET <sup>#2</sup> | Action                              | Y                  | N  | N     | N  |
| 35  | IM.ACTION_TYPE <sup>#2</sup>  | Action type                         | Y                  | N  | N     | N  |
| 36  | E.*                           | Program-specific extended attribute | N                  | N  | N     | Y  |

Legend:

Y: Can be specified

N: Cannot be specified

#1

There are no differences in the items that can be specified for file versions 1 through 10.

#2

These items are compatible with version 8. If DESC\_VERSION is 10 or earlier (definition for version 8 or earlier), these attributes are converted as follows:

E.ACTION\_TARGET → E.@JP1IM\_ACTCONTROL

IM.ACTION\_TYPE → E.@JP1IM\_ACTTYPE

AttrOrder = *sort-order*

Specifies the display column location relative to the left margin. If you specify 1, the attribute is displayed as the first (leftmost) item in the list of events. Do not specify the same value for more than one item.

Do not specify 0 because it is used by the system.

If there are any errors in the user profile, the Event Console window might not display correctly. For this reason, we recommend that you use the Preferences window of JP1/IM - View to define user profiles.

ColumnSize = *column-width*

Specifies the column width. The permitted value range is from 1 to 1,000.

## Notes

- Specify each user profile carefully because the contents of this file affect overall event console operation. Do not change any attribute or attribute value that is not explained here. If such an attribute or attribute value is changed, the event console might not function correctly.
- Because a user profile might be overwritten during JP1/IM - View operation or termination processing, make sure that you terminate JP1/IM - View before editing a user profile.
- There is one user profile for each manager. Therefore, if you have changed the manager for logging in, you must change the profile at the connection destinations.
- When you intend to edit the contents of the `defaultUser` file, you must make a backup before editing the file.
- Using JP1/Base's user management to delete a user does not delete the user profile for that user.
- If you use JP1/Base's user management to rename a user, the user's existing user profile is not inherited.
- If a user profile contains an error, such as an attribute value outside the permitted range of values, the event console might not function correctly.

## ◆ Communication environment definition file (console.conf.update)

### Format

```
[logical-host-name\JP1CONSOLEMANAGER\EVCONS]
"COM_SO_TIMEOUT"=dword:hexadecimal-value

[JP1_DEFAULT\JP1CONSOLE_CMD]
"COM_SO_TIMEOUT"=dword:hexadecimal-value
"COM_RETRY_COUNT"=dword:hexadecimal-value
"COM_RETRY_INTERVAL"=dword:hexadecimal-value
"COM_RMI_TIMEOUT"=dword:hexadecimal-value
```

### File

`console.conf.update` (model file for the communication environment definition file)

### Storage directory

In Windows

*Console-path*\default\

In UNIX

/etc/opt/jplcons/default/

### Description

This file defines communication processing (timeout period) among JP1/IM - Manager, the viewer, and the `jcochstat` command.

When a low-speed line is used in the network for communication between the viewer and JP1/IM - Manager or when the viewer's workload is high, timeouts might occur during the viewer's communication processing, resulting in communication errors. You can prevent such communication errors by modifying the timeout period.

When the `jcochstat` command is used from another manager to change the action status of a JP1 event at the local host, a communication error might occur due to a timeout during communication processing. Modifying the timeout period and the connection retry count might resolve the problem, preventing a recurrence of the communication error.

If you are using JP1/IM - View (event console), you must also change the communication environment definition file for JP1/IM - View (event console) (`view.conf.update`).

The required definitions are provided as a model file. To change the settings, copy the model file and edit the copy after renaming the copy to definition file (for Windows: `console-path\conf\console.conf`, for UNIX: `/etc/opt/jplcons/conf/console.conf`).

## When the definitions are applied

The definition takes effect after JP1/IM - Manager is restarted by executing the `jbssetcnf` command.

## Information that is specified

[*logical-host-name*\JP1CONSOLEMANAGER\EVCONS]

Specifies the key name for Event Console Service environment settings.

For *logical-host-name*, specify `JP1_DEFAULT` for the physical host and *logical-host-name* for a logical host.

"COM\_SO\_TIMEOUT"=dword:*hexadecimal-value*

Specifies as a hexadecimal value the timeout period in milliseconds. The default value is `dword:0000EA60` (60,000 milliseconds).

The range of values that can be specified is from `0x00000001` to `0x0036EE80` (3,600,000 milliseconds).

The specified value must not exceed the value specified for `COM_RMI_TIMEOUT` (default: `0000EA60`) in the `console.conf.update` communication environment definition file and the `view.conf.update` communication environment definition file. Additionally, check the setting value (timeout period) on the connection source.

[JP1\_DEFAULT\JP1CONSOLE\_CMD]

Specifies the key name for the `jcochstat` command environment settings.

"COM\_SO\_TIMEOUT"=dword:*hexadecimal-value*

Specifies as a hexadecimal value the timeout period in milliseconds. The default value is `dword:0000EA60` (60,000 milliseconds).

The range of values that can be specified is from `0x00000001` to `0x0036EE80` (3,600,000 milliseconds).

The specified value must not exceed the value specified for `COM_RMI_TIMEOUT` (default: `0000EA60`) in the communication environment definition file (`view.conf.update`).

"COM\_RETRY\_COUNT"=dword:*hexadecimal-value*

Specifies as a hexadecimal value the retry count to be applied in the event of a communication error. The default is `dword:00000003` (3 times).

The range of values that can be specified is from `0x00000001` to `0x7fffffff` (2,147,483,647 times).

"COM\_RETRY\_INTERVAL"=dword:*hexadecimal-value*

Specifies as a hexadecimal value the wait time in milliseconds between retry attempts. The default is `dword:00000BB8` (3,000 milliseconds).

The range of values that can be specified is from `0x00000001` to `0x7fffffff` (2,147,483,647 milliseconds).

"COM\_RMI\_TIMEOUT"=dword:*hexadecimal-value*

Specifies as a hexadecimal value the timeout period in milliseconds for the event action status to change. The permitted value range is from 0000EA60 to 0036EE80 (from 60,000 to 3,600,000 milliseconds). The default is dword:0000EA60 (60,000 milliseconds).

If the KAVB1205-E message is displayed frequently, set a longer timeout period.

## Example definition

```
[JP1_DEFAULT\JP1CONSOLEMANAGER\EVCONS]
"COM_SO_TIMEOUT"=dword:000009C4

[JP1_DEFAULT\JP1CONSOLE_CMD]
"COM_SO_TIMEOUT"=dword:0000EA60
"COM_RETRY_COUNT"=dword:00000003
"COM_RETRY_INTERVAL"=dword:00000BB8
```

Make sure that the end of the file is at the beginning of the last line.

## ◆ Health check definition file (jcohc.conf)

### Format

```
[HEALTHCHECK]
ENABLE={true | false}
FAILOVER={true | false}
EVENT={true | false}
COMMAND=command
NO_RESPONSE_TIME=no-response-time
ERROR_THRESHOLD=no-response-count-treated-as-error
BASE_NO_RESPONSE_TIME=no-response-time
BASE_ERROR_THRESHOLD=no-response-count-treated-as-error
[End]
```

### File

jcohc.conf (health check definition file)

jcohc.conf.model(model file for the health check definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\health\

For a logical host:

*shared-folder*\jplcons\conf\health\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/health/

For a logical host:

*shared-directory/jplcons/conf/health/*

## Description

This file defines whether the health check function is to be enabled. If you enable the health check function, you can also define whether errors are to be notified by issuing a JP1 event or by executing a notification command.

You must specify this definition file by using the character encoding supported by JP1/IM - Manager.

If you have deleted the health check definition file (`jcohc.conf`), copy the model file for the health check definition file (`jcohc.conf.model`) under the name `jcohc.conf` and then edit the definition in the copy, if necessary.

The health check function cannot monitor Central Scope Service (`jcsmain`).

When you enable the health check function by using this definition file, you gain the capability to check whether each process of JP1/IM - Manager and the event service of JP1/Base on the local host is running normally.

The health check function can detect errors in the following processes:

- Event Console Service (`evtcon`)
- Automatic Action Service (`jcamain`)
- Event Base Service (`evflow`)
- Event Generation Service (`evgen`)
- Event service (`jevservice`)

If any of these processes hang up<sup>#</sup> or terminate abnormally, the health check function can issue a JP1 event or execute a specified notification command to prompt the operator to recover the process.

#

A process hang-up is a status in which a process can no longer accept processing requests due to deadlock or looping.

## When the definitions are applied

The settings in the health check definition file take effect at the following times:

- When JP1/IM - Manager is started.
- When the file is reloaded by the `jco_spmd_reload` command.

## Information that is specified

`ENABLE={true | false}`

Specifies whether the health check function is to be enabled.

Specify either `true` or `false`. To enable the health check function, specify `true`; to disable the function, specify `false`. The default is `false`.

When the health check function has been enabled and it detects an error, a message (`KAVB8060-E` or `KAVB8062-E`) is output to the integrated trace and the Windows event log (`syslog`) reporting whether the `EVENT` setting in the health check definition file is `true` or `false`.

FAILOVER={true | false}

Specifies whether a JP1/IM - Manager operation is to be performed when an error is detected by the health check function when you are operating in a cluster system. Specify `true` if the operation is to be performed, or specify `false` if the operation is not to be performed. The default is `false`. If you do not use a cluster system, do not change the default setting.

- In Windows

When `true` is specified, JP1/IM - Manager is terminated when an error is detected. When the health check function detects an error, it notifies the cluster system of the error in JP1/IM - Manager by stopping JP1/IM - Manager. If you set the cluster system to fail over when a JP1/IM - Manager error occurs, failover can take place when an error is detected.

- In UNIX

When `true` is specified, the JP1/IM - Manager process in which the error was detected is terminated. When the health check function detects an error, it notifies a cluster system of the error in JP1/IM - Manager by stopping JP1/IM - Manager. If you set the cluster system so that, on detection of an error, it is stopped forcibly by the `jco_killall.cluster` command and then failed over, failover can take place when an error is detected.

EVENT={true | false}

Specifies whether JP1 events (event ID: 2012 and 2013) are to be issued when an error is detected by the health check function.

Specify either `true` or `false`. If JP1 events are to be issued, specify `true`; otherwise, specify `false`.

The default is `true`. When `true` is specified, a JP1 event (event ID: 2014) is also issued in the following case:

- The health check function detects abnormal recovery.

For details about JP1 events, see [3.2.2 Details of JP1 events output by JP1/IM - Manager](#).

COMMAND=*command*

Specifies the notification command that is to be executed when an error is detected by the health check function.

You can execute the following types of commands:

When the host executing the command is Windows:

- Executable file (`.com`, `.exe`)
- Batch file (`.bat`)
- JP1/Script script file (`.spt`)  
(An appropriate association must have been set so that an `.spt` file can be executed.)

When the host executing the command is UNIX:

- Executable file (with execution permissions)
- Shell script (with execution permissions)

The following notes apply to defining a notification command:

- Everything from `COMMAND=` to the linefeed code is defined as a single command.
- The maximum length of a command is 1,023 bytes. This length includes spaces, but does not include the linefeed code. If the length exceeds 1,023 bytes, the default value is assumed. If you specify variables and the character string obtained by expanding variables exceeds 1,023 bytes, the command will not execute. In such a case, the message `KAVB8072-E` is output to the integrated trace log.
- If you specify a variable, specify it immediately after `$`. The following table lists and describes the variables that can be specified.

Table 2–25: Variables that can be specified in notification commands

| Variable name | Description                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HCHOST        | Name of host resulting in the error                                                                                                                             |
| HCFUNC        | Name of function resulting in the error<br>(evflow, jcamain, evtcon, evgen, or jevservice)                                                                      |
| HCPNAME       | Name of process resulting in the error<br>(evflow, jcamain, evtcon, evgen, or jevservice)                                                                       |
| HCPID         | <ul style="list-style-type: none"> <li>For evflow, jcamain, evtcon, or evgen<br/>ID of process resulting in the error</li> <li>For jevservice<br/>-1</li> </ul> |
| HCDATE        | Date the error occurred (YYYY/MM/DD)                                                                                                                            |
| HCTIME        | Time the error occurred (hh:mm:ss)                                                                                                                              |

- For the notification command, specify a command that will always terminate. If you set a batch file (Windows) or shell script (UNIX), make sure that it will terminate with `exit 0`. If the specified command does not terminate or uses the GUI, processes of the executed notification command will remain unresolved.
- The notification command specified in `COMMAND` inherits the execution environment of JP1/IM - Manager.
- The notification command is executed with the execution permissions of JP1/IM - Manager (Windows: `SYSTEM` user; UNIX: `root`).
- Specify in `COMMAND` the full path of the notification command.

Use the `jcohctest` command to test thoroughly whether the set notification command functions successfully. For details about the `jcohctest` command, see [jcohctest](#) in *1. Commands*.

- The default is `COMMAND=`, in which case no notification command is executed.
- To use `$`, specify `$$`.
- In Windows, if you execute a command in the `%WINDIR%\System32` folder, the WOW64 redirect functionality redirects execution to the same command in the `%WINDIR%\SysWow64` folder. If there is no applicable command in the destination folder, command execution might fail. Make sure that the applicable command is in the `%WINDIR%\System32` folder when you specify it for execution.

`NO_RESPONSE_TIME=no-response-time`

Specifies in seconds the amount of time to wait for a response to be sent from the JP1/IM - Manager process. The permitted value range is from 60 to 3,600 seconds. The default is 60 seconds.

If the value that is specified is outside the permitted value range or the definition is omitted, the default value (60 seconds) is assumed.

Note that this parameter is not included in the health check definition file (`jcohc.conf`) that is deployed when JP1/IM - Manager is installed. If you want to change the default value, you must add the parameter.

`ERROR_THRESHOLD=no-response-count-treated-as-error`

Specifies the number of times to wait for the set no-response time to elapse before assuming that an error has occurred in the JP1/IM - Manager process. The permitted value range is from 1 to 60 times. The default is 3 times.

If the value that is specified is outside the permitted value range or the definition is omitted, the default value (3 times) is assumed.

BASE\_NO\_RESPONSE\_TIME=*no-response-time*

Specifies in seconds the interval for checking the JP1/Base event service for the set no-response time on Manager. The permitted value range is from 60 to 3,600 seconds. The default is 300 seconds.

If the value that is specified is outside the permitted value range or the definition is omitted, the default value (300 seconds) is assumed.

BASE\_ERROR\_THRESHOLD=*no-response-count-treated-as-error*

Specifies the number of times to wait for the set no-response time to elapse before assuming that an error has occurred in the JP1/Base event service on Manager. The permitted value range is from 1 to 60 times. The default is 2.

If the value that is specified is outside the permitted value range or the definition is omitted, the default value (2 times) is assumed.

## Example definition

Issue a JP1 event and execute the `jcohc01.exe` notification command when an error is detected by the health check function:

```
[HEALTHCHECK]
ENABLE=true
FAILOVER=false
EVENT=true
COMMAND=C:\Command\jcohc01.exe
NO_RESPONSE_TIME=60
ERROR_THRESHOLD=3
BASE_NO_RESPONSE_TIME=300
BASE_ERROR_THRESHOLD=2
[End]
```

## ◆ Event guide information file (jco\_guide.txt)

### Format

```
DESC_VERSION=file-version

[EV_GUIDE_event-guide-number]
EV_USER=JP1-user-name
EV_COMP=attribute-name:attribute-value
EV_GUIDE=event-guide-message
[END]
[EV_GUIDE_event-guide-number]
EV_COMP=attribute-name:attribute-value
EV_COMP=attribute-name:attribute-value
EV_FILE=event-guide-message-file-name
[END]
:
```

### File

sample\_jco\_guide\_ja.txt (sample file of the event guide information file (Japanese))

sample\_jco\_guide\_en.txt (sample file of the event guide information file (English))

sample\_jco\_guide\_ja.txt.model (model file for the event guide information sample file (Japanese))

sample\_jco\_guide\_en.txt.model (model file for the event guide information sample file (English))

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\guide\

For a logical host:

*shared-folder*\jplcons\conf\guide\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/guide/

For a logical host:

*shared-directory*/jplcons/conf/guide/

## Description

This file defines event guide information for JP1 events. The information specified in this file is displayed in the Event Details window of JP1/IM - View or the Event Detail window of the integrated operation viewer.

The maximum size of an event guide information file is 1 megabyte. An event guide information file can contain up to 1,000 blocks.

Use the language encoding supported by JP1/IM - Manager to specify the event guide information file.

You must create an event guide information file under the name `jco_guide.txt`. Copy the `sample_jco_guide_ja.txt` or `sample_jco_guide_en.txt`, depending on the language code used by JP1/IM - Manager, and then rename the file `jco_guide.txt` before you use it. Store the event guide information file in the same directory that stores the sample file. Note that the event guide information file cannot have a user-selected name, unlike the file specified in the `EV_FILE` parameter (event guide message file).

If an issued JP1 event matches multiple event guide information items, the first item specified in the event guide information file is effective.

When `#` is specified, any text following `#` is treated as a comment. Note that a comment cannot be specified after the start tag, attribute information, or the end tag. An error results if a comment is specified following the start tag or the end tag. A comment that is specified following an attribute value is treated as part of the attribute value.

To use `\`, specify `\\`. If `\` is used in a character combination other than `\n` or `\$`, a log is output and the line containing `\` is ignored.

The event guide information file and event guide message file are not checked for HTML syntax errors.

## When the definitions are applied

Once the event guide information file has been edited, the definitions in the file take effect when JP1/IM - Manager is restarted or when the `jco_spmc_reload` command is executed. If there is no display area for event guide information in the Event Details window when you log in to JP1/IM - View or the Event Detail window of the integrated operation

viewer, apply the definitions and then re-log in to JP1/IM - View or the Event Detail window of the integrated operation viewer. The display area should appear.

After you have edited the event guide message file, you can display the new information by reloading the Event Details window.

## Information that is specified

`DESC_VERSION=file-version`

Specifies the file version of the event guide information file. The specifiable values are 1 and 2. When 2 is specified, you can specify the `EV_USER` parameter.

`[EV_GUIDE_event-guide-number]`

This is the start tag for event guide information. The information from the `[EV_GUIDE_event-guide-number]` to the `[END]` tag constitutes a single definition block. Between this parameter and `[END]`, specify a comparison condition for determining the JP1 events that are to be displayed in the Event Details window and the message to be displayed. For *event-guide-number*, specify a decimal number in the range from 1 to 9999.

When there are multiple definition blocks, the event guide numbers need not be in numerical order. However, an error results if the same event guide number is specified more than once, in which case the definition block with the duplicated event guide number is ignored. Note that `[EV_GUIDE_1]` and `[EV_GUIDE_0001]` are different.

Specify a unique character string in each `EV_GUIDE_event-guide-number`. If an invalid character string is specified, a log is output and the corresponding specification is ignored.

If an attribute specified for `EV_GUIDE_event-guide-number` is not permitted, the corresponding specification is ignored.

`EV_USER=JP1-user-name`

Specifies the JP1 user name to be displayed in the event guide message. You can specify 1 to 31 bytes of characters. Only one-byte alphanumeric characters can be used. Alphabetic characters are not case sensitive. If you specify this parameter, specify 2 for `DESC_VERSION`. You can specify this parameter only once. If the parameter is omitted, all JP1 users are assumed as applicable users.

This parameter can be specified only when the version of JP1/IM - Manager is 09-50 or later. You can specify a maximum of 100 JP1 user names by separating them with one or more spaces.

Example:

```
EV_USER=jpluser1 jpluser2 jpluser3
```

`EV_COMP=attribute-name:attribute-value`

Specify this parameter for each attribute that is to be used for comparison with JP1 events. When multiple attributes are specified, they are assumed to be connected by the AND condition. For example, if the `EV_COMP` parameter is specified twice, the event guide message is displayed in the Event Details window only when both of the conditions are satisfied.

If you specify an event ID for the attribute name in an `EV_COMP` parameter, you can specify either `B.ID` or `B.IDBASE`. In `B.ID`, specify the 16-digit attribute value in the format *basic-part:extended-part*. In `B.IDBASE`, specify the 8-digit basic part.

Example:

- `EV_COMP=B.ID:00004107:00000000`
- `EV_COMP=B.IDBASE:00004107`

You can specify a maximum of 100 `EV_COMP` conditions. For an example of using more than one `EV_COMP` condition, see the example definition below.

Note that a business group name cannot be used for the event-issuing server name (B . SOURCESERVER), the target event server name (B . DESTSERVER), and the event source host name (E . JP1\_SOURCEHOST). If you specify a business group name, it is treated as a host name.

#### *attribute-name*

Specifies one of the following as the attribute:

- JP1 event basic attribute: If you specify this attribute, use the format B . *attribute-name*.
- JP1 event extended attribute: If you specify this attribute, use the format E . *attribute-name*.

Note that the reason for registration (B . REASON) and code set (B . CODESET) cannot be specified.

If you specify the registration time (B . TIME) or the arrival time (B . ARRIVEDTIME) for *attribute-name*, the total number of milliseconds after UTC January 1, 1970 at 00:00:00 is compared.

Example: Specify a JP1 event of which the arrival time is 10:20:00.000 (total number of milliseconds: 1371000000000) on June 12, 2013

```
EV_COMP=B.TIME:1371000000000
```

#### *attribute-value*

Specifies as a regular expression the value of the attribute specified in *attribute-name*. For the regular expression, use an extended regular expression. For details about regular expressions, see *Appendix G. Regular Expressions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

By default, the specified regular expression is compared with the entire attribute value of the JP1 event. The condition is satisfied only if they match exactly.

To accept a partial match, execute the `jbssetcnf` command specifying a file that contains the common definition information shown below in an argument and then restart JP1/IM - Manager to apply the definition. When you create the definition file, make sure that the end of the file is at the beginning of the last line.

For a physical host

```
[JP1_DEFAULT\JP1CONSOLEMANAGER]
"GUIDE_EV_COMP"="find"
```

For a logical host

```
[logical-host-name\JP1CONSOLEMANAGER]
"GUIDE_EV_COMP"="find"
```

To reset the definition to a complete match (default), specify `match` for the value of the `GUIDE_EV_COMP` common definition information.

If the common definition information is missing or the specified value is invalid, the system assumes `match` for a complete match.

Note that the common definition information is not set at the time of installation.

When you specify an IPv6 address for a source IP address (B . SOURCEIPADDR) and the target IP address (B . DESTIPADDR), use lowercase alphabetic characters as in the following example:

```
0011:2233:4455:6677:8899:aabb:ccdd:eeff
```

Also note that abbreviated IP addresses such as the following cannot be specified:

```
2012:7:8::a:b
```

When you specify the registered time (B . TIME) or the arrived time (B . ARRIVEDTIME), specify the number of seconds in milliseconds starting from UTC 1970-01-01 00:00:00.

#### *EV\_GUIDE=event-guide-message*

Specifies a character string that is to be displayed as the event guide information. The specified character string is displayed in the event guide information area in the Event Details window (in **Guide** under **Message**).

Note that you can specify this parameter only once between [*EV\_GUIDE\_event-guide-number*] and [END].

If you specify `EV_GUIDE=event-guide-message` and `EV_FILE=event-guide-message-file-name` together, the specification of `EV_FILE=event-guide-message-file-name` takes precedence.

To use `\` in the message, specify `\\`. To use `$`, specify `\$`. To use a linefeed code in the message, specify `\n`.

You can use HTML tags and specify variables for JP1 event attributes in *event-guide-message*.

- Specifying HTML tags

If you use HTML tags, you can display the event guide message in HTML format in the Event Details window (for details about the HTML tags that can be specified, see [Table 2-29 HTML tags that can be used in the event guide message file](#), in the description of `EV_FILE`).

- Specifying variables for JP1 event attributes

If you specify `$B.attribute-nameΔ` or `$E.attribute-nameΔ` in the message, the attribute value corresponding to the JP1 event attribute name is expanded in the message (Δ indicates a space). Note that the reason for registration (`B.REASON`) and code set (`B.CODESET`) cannot be specified. If there is no corresponding attribute, the attribute is replaced with blanks.

The table below lists the attribute names that can be specified in messages. For details about the attributes of JP1 events, see [3.1 Attributes of JP1 events](#).

**Table 2–26: List of attribute names that can be specified in messages**

| JP1 event attribute |                           | Specification in message                                                             |
|---------------------|---------------------------|--------------------------------------------------------------------------------------|
| Basic attributes    | Serial number             | <code>B.SEQNO</code>                                                                 |
|                     | Event ID                  | Specify either of the following:<br>1. <code>B.ID</code><br>2. <code>B.IDBASE</code> |
|                     | Source process ID         | <code>B.PROCESSID</code>                                                             |

| Extended attributes | Event level               | <code>E.SEVERITY</code>                                                              |
|                     | User name                 | <code>E.USER_NAME</code>                                                             |
|                     | Product name              | <code>E.PRODUCT_NAME</code>                                                          |
|                     | Object type               | <code>E.OBJECT_TYPE</code>                                                           |
|                     | Object name               | <code>E.OBJECT_NAME</code>                                                           |
|                     | Root object type          | <code>E.ROOT_OBJECT_TYPE</code>                                                      |
|                     | Root object name          | <code>E.ROOT_OBJECT_NAME</code>                                                      |
|                     | Object ID                 | <code>E.OBJECT_ID</code>                                                             |

| JP1 event attribute |                          | Specification in message |
|---------------------|--------------------------|--------------------------|
|                     | Occurrence               | E.OCCURRENCE             |
|                     | Start time               | E.START_TIME             |
|                     | End time                 | E.END_TIME               |
|                     | Result code              | E.RESULT_CODE            |
|                     | Event source host name   | E.JP1_SOURCEHOST         |
|                     | Other extended attribute | E.xxxxxx <sup>#</sup>    |

#:

You can also specify JP1 product-specific extended attributes. For example, the product-specific extended attribute for the JP1/AJS job execution host is E.C0. For details about the product-specific extended attributes, consult the documentation for the products that issue JP1 events.

You can specify for an event guide message a maximum of 196,608 characters. If more than 196,608 characters are specified, the portion in excess of 196,608 characters will not be displayed in the Event Details window.

The event guide message can display a Web page of related products without unreadable text by specifying replacement characters listed in the table below.

**Table 2–27: Replacement characters that can be specified**

| Specification format                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$B.attribute-nameΔ<br>\$E.attribute-nameΔ                           | Expand the attribute value as is.<br>When guide information is in HTML format, use HTML encoding.<br>Specify the attribute value in this format to display the JP1 event attribute value as part of the text to be displayed in an event guide message.<br>Example: \$B.MESSAGEΔ                                                                                                                                                                        |
| \$B.attribute-name\$URLENCA<br>\$E.attribute-name\$URLENCA           | Handle the attribute value as a UTF-8 string for URL encoding and expand it.<br>Use this format to pass the JP1 event attribute value as a UTF-8 string to be used as the argument (URL parameter) of the Web page application.<br>Example: <a href="http://host/page?msg=\$B.MESSAGE\$URLENCA">                                                                                                                                                        |
| \$B.attribute-name\$ENCA<br>\$E.attribute-name\$ENCA                 | Perform Base64 encoding for the attribute value as a UTF-8 string and expand it.<br>Use this format to display the Base64-encoded JP1 event attribute value as a UTF-8 string as part of the text to be displayed in an event guide message.<br>However, to pass the value as an argument (URL parameter) of a Web page application, use the variables \$B.attribute-name\$ENC\$URLENCA, \$E.attribute-name\$ENC\$URLENCA<br>Example: \$B.MESSAGE\$ENCA |
| \$B.attribute-name\$ENC\$URLENCA<br>\$E.attribute-name\$ENC\$URLENCA | Perform Base64 encoding for the attribute value as a UTF-8 string, and then perform URL-encoding to expand it.<br>Use this format to pass the Base64 value of the JP1 event attribute value as an argument (URL parameter) of the Web page application.<br>Example: <a href="http://host/page?msg=\$B.MESSAGE\$ENC\$URLENCA">                                                                                                                           |

Note:

When you specify \$URLENC or \$ENC, you must specify 2 as the value for DESC\_VERSION.

**EV\_FILE=event-guide-message-file-name**

Specifies the full path name of a file that contains the text for the event guide message that is to be displayed in the Event Details window. You can specify this parameter only once between [EV\_GUIDE\_event-guide-number] and [END]. If nothing is specified for *event-guide-message-file-name*, the file names in the following table are assumed.

**Table 2–28: Event guide message file name**

| OS      | Event guide message file name                                              |
|---------|----------------------------------------------------------------------------|
| Windows | <i>Console-path\conf\guide\EV_GUIDE_event-guide-number.txt</i>             |
|         | <i>shared-folder\jplcons\conf\guide\EV_GUIDE_event-guide-number.txt</i>    |
| UNIX    | <i>/etc/opt/jplcons/conf/guide/EV_GUIDE_event-guide-number.txt</i>         |
|         | <i>shared-directory/jplcons/conf/guide/EV_GUIDE_event-guide-number.txt</i> |

Express the file name using from 1 to 1,024 characters, including the path. If the specified file name exceeds 1,024 characters, an error results when JP1/IM - Manager starts or when the event guide message file is called from JP1/IM - View or the integrated operation viewer.

You can specify any file name and extension for the event guide message file. We recommend that you select a file name that is easy to manage; for the extension, use `.txt` if the event guide message is in TXT format and `.html` or `.htm` if the event guide message is in HTML format.

Example: `jco_guidemes001_AJS2.txt` or `jco_guidemes001_AJS2.htm`

#### *Event guide message file*

Specify in the event guide message file in TXT or HTML format the information that you want to be displayed in the Event Details window. The information that you can specify in the event guide information file is the same as for `EV_GUIDE`. In other words, you can use HTML tags and variables for the attributes of JP1 events. To use a backslash sign (`\`) in a message, write it as `\\`. To use the dollar sign (`$`), write it as `\$`. To insert a linefeed in a message, write it as `\n`.

However, `EV_GUIDE` can be used only to specify a one-line message, whereas with the event guide message file you can use linefeed codes for a formatted message.

You can store the created event guide message file in any folder.

The maximum size of an event guide message file is 1 megabyte. If the file size exceeds 1 megabyte, an error occurs when the event guide message file is loaded into the Event Details window of JP1/IM - View or the integrated operation viewer.

The table below lists and describes the HTML tags and attributes that can be used when you create an event guide message file in HTML format. If any other HTML tags are used, the operational results cannot be guaranteed.

**Table 2–29: HTML tags that can be used in the event guide message file**

| Tag             | Attribute            | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HTML            | --                   | Declares that this is an HTML text. This tag is mandatory.                                                                                                                                                                                                                                                                                                                                   |
| HEAD            | --                   | Declares the header for the HTML text.<br>This tag is mandatory.                                                                                                                                                                                                                                                                                                                             |
| BODY            | --                   | Declares the body of the HTML text.<br>This tag is mandatory.                                                                                                                                                                                                                                                                                                                                |
| A <sup>#1</sup> | HREF="URL"           | Specifies a linkage-target URL. <sup>#2, #3</sup> You can specify URLs beginning with <code>http://</code> or <code>https://</code> .<br>Operation with other URLs is unpredictable.<br>The link specified here is displayed in the Event Details window (HTML format). Clicking the link starts a Web browser and accesses the specified URL. You can encode a maximum of 2,083 characters. |
|                 | TARGET <sup>#5</sup> | Specifies the name of the destination window for the page indicated by the URL specified in HREF.<br>If a destination window with the same name is found in the range of the same session as that of the WWW browser displaying the Integrated Operation Viewer, the window is used as a display destination.                                                                                |

| Tag                    | Attribute                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                             | <p>If the destination window is not found, a new window is opened and used as the display destination.</p> <p>This attribute can accept the following characters:</p> <ul style="list-style-type: none"> <li>• Half-width upper-case and lower-case alphabetic characters</li> <li>• Half-width numbers</li> <li>• Space characters</li> <li>• Symbols (! Legend:

--: None

#1: The interpretation of the URL in the A tag and the screen to be displayed are dependent on the WWW browser and other aspects of the environment.

#2: The following is a coding example of a URL used to link with JP1/Navigation Platform.

Example:

```
http://hostA:8080/ucnpBase/portal/screen/Home/action/
PLoginUser?contentId=f24077e7-0136-1000-8000-00000ad20b6f-0
```

For details about linking with JP1/Navigation Platform, see the descriptions of the URL for calling Navigation Platform from JP1 products in the JP1/Navigation Platform manuals.

#3: For details about the URL for linking with JP1/AJS, see the JP1/AJS manuals.

#4: In the integrated operation viewer window, Japanese strings are not italicized even with the I tag.

#5: This attribute is available only for the Integrated Operation Viewer window.

[END]

Specifies the end tag for the event guide information. This item is not case sensitive.

## Example definition

```
# JP1/IM-CC Guide Information File.
```

```
DESC_VERSION=1
[EV_GUIDE_001]
EV_COMP=B.ID:00004107:00000000
EV_COMP=E.SEVERITY:Error
EV_GUIDE=The job terminated abnormally.\nCheck whether an error has occurred on the $E.C0 host.
[END]
```

## ◆ Status event definition file (processupdate.conf)

### Format

```
[PROCESSUPDATE]
PROCESS_UPDATE_EVENT_OPTION={true | false}
[End]
```

### File

processupdate.conf (status event definition file)

processupdate.conf.model (model file for the status event definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\processupdate\

For a logical host:

*shared-folder*\jplcons\conf\processupdate\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/processupdate/

For a logical host:

*shared-directory*/jplcons/conf/processupdate/

### Description

This file defines whether a JP1 event is to be issued when the action status changes.

### When the definitions are applied

The setting specified in the status event definition file takes effect at the following time:

- When JP1/IM - Manager starts

## Information that is specified

`PROCESS_UPDATE_EVENT_OPTION={true | false}`

Specifies whether a JP1 event (event ID: 3F11) is to be issued when the action status changes. The value is not case sensitive.

Specify `true` if a JP1 event is to be issued when the action status changes.

Specify `false` if a JP1 event is not to be issued when the action status changes. The default is `false`.

If this parameter is omitted or an invalid value is specified, `false` is assumed.

For details about JP1 events, see [3.2.2 Details of JP1 events output by JP1/IM - Manager](#).

## Note

- If you specify that a JP1 event is to be issued, one instance of the JP1 event with ID 3F11 will be issued for each JP1 event for which an action is taken. For example, if you select multiple JP1 events on the **Severe Events** page on the Event Console window and their action status changes, as many JP1 events with ID 3F11 will be issued as there are JP1 events whose action status has changed.

You should not enable this function when the action status of a large number of JP1 events will be changed by processing in the batch mode.

## ◆ Correlation event generation system profile (egs\_system.conf)

### Format

```
VERSION=1

START_OPTION={cold | warm}
```

### File

`egs_system.conf` (correlation event generation system profile)

`egs_system.conf.model` (model file for the correlation event generation system profile)

### Storage directory

In Windows

For a physical host:

`Console-path\conf\evgen\profile\`

For a logical host:

`shared-folder\jplcons\conf\evgen\profile\`

In UNIX

For a physical host:

`/etc/opt/jplcons/conf/evgen/profile/`

For a logical host:

`shared-directory/jplcons/conf/evgen/profile/`

## Description

This file defines the start and stop operations for the Event Generation Service.

## When the definitions are applied

The settings in the correlation event generation system profile take effect at the following times:

- When JP1/IM - Manager starts
- When the file is reloaded by the `jco_spmd_reload` command

## Information that is specified

VERSION=1

Specifies the file version. There is no need to edit this parameter. If this parameter is omitted or a numeric value other than 1 is specified, VERSION=1 is assumed.

START\_OPTION={cold | warm}

Specifies the startup option for the Event Generation Service.

Specify the value that corresponds to the operation to be performed during start and stop processing. The permitted values are `cold` and `warm`. The default is `warm`. This value is not case sensitive. If the parameter is omitted or an invalid value is specified, `warm` is assumed.

The operations are different depending on whether or not the integrated monitoring database is used.

The table below describes the operation of the Event Generation Service during start and stop processing depending on whether `cold` or `warm` is specified when the integrated monitoring database is not used. Change the value as appropriate to your operations.

Table 2–30: Operation of the Event Generation Service during start and stop processing depending on the start option (when the integrated monitoring database is not used)

| Start option | Operation of Event Generation Service                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                    |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | Operation during startup processing <sup>#1</sup>                                                                                                                                                                                                                                                          | Operation during stop processing                                                                                                                                                                                   |
| cold         | When the start option was set to <code>cold</code> during the previous stop processing:<br>JP1 events registered after the Event Generation Service started are subject to generation processing.                                                                                                          | All correlation events under generation processing fail and are output to the correlation event generation history file.                                                                                           |

| warm         | When the start option was set to <code>cold</code> during the previous stop processing:<br>JP1 events are subject to generation processing beginning with the one that immediately follows the last JP1 event acquired by the Event Generation Service during the previous stop processing.                | Information about the last JP1 event acquired before the service stopped, details of the generation processing, and the correlation event generation definition information are output to internal logs and saved. |
|              | When the start option was set to <code>warm</code> during the previous stop processing:<br>The correlation event generation processing performed during the previous stop processing is inherited, and JP1 events are subject to generation processing beginning with the one that immediately follows the |                                                                                                                                                                                                                    |

| Start option | Operation of Event Generation Service                                                                     |                                  |
|--------------|-----------------------------------------------------------------------------------------------------------|----------------------------------|
|              | Operation during startup processing <sup>#1</sup>                                                         | Operation during stop processing |
|              | last JP1 event acquired by the Event Generation Service during the previous stop processing <sup>#2</sup> |                                  |

#1

When the Event Generation Service starts for the first time, it functions as follows, regardless of the start option value:

- The Event Generation Service acquires JP1 events that are registered after the Event Generation Service starts.
- The Event Generation Service loads the correlation event generation definition and starts processing according to the definition.

Note that the default is that correlation events are not generated because the correlation event generation definition has not been set.

#2

If the correlation event generation definition used when JP1/IM - Manager stopped differs from the definition used the next time JP1/IM - Manager starts, all correlation events under generation processing fail. After the contents are cleared, JP1 events are subject to generation processing again starting with the one that immediately follows the JP1 event acquired during the previous stop processing.

When the integrated monitoring database is used, the correlation event generation function associates the correlation event generation definition with the event acquired by the Event Base Service and then generates the correlation event.

It is possible to choose the position at which the Event Base Service is to start acquiring JP1 events from the JP1/Base event database after startup. Use the `-b` option to the `jcoimdef` command to choose where to start JP1 event acquisition.

The correlation event generation processing varies depending on the combination of the start option and the JP1 event acquisition start position, as shown in the following table.

**Table 2–31: Operation of the Event Generation Service during start and stop processing depending on the start option (when the integrated monitoring database is used)**

| Start option | Value of -b option | Processing                                                                                                                                                                                                                                                                                                                                      |
|--------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| warm         | -1 (default value) | The status of the JP1 events under correlation event generation processing is inherited.<br><br>JP1 event acquisition starts from the next JP1 event after the last JP1 event acquired when the service stopped. If there is no such JP1 event, acquisition starts from the oldest JP1 event among the events registered in the event database. |
|              | 0 to 144           | Message KAJV2316-W is output, and the status of the JP1 events under correlation event generation processing is not inherited.                                                                                                                                                                                                                  |
| cold         | -1 to 144          | All correlation event generation processing stops and the service terminates. The status of the JP1 events under correlation event generation processing is not inherited.                                                                                                                                                                      |

Note that when the integrated monitoring database is used, JP1 events that were once subject to correlation event generation processing are not subject to correlation event generation processing again.

If you run JP1/IM - Manager in a cluster system, change the setting to `warm`.

In the event of failover, products are stopped and started in the following order: stopping JP1/IM - Manager → stopping JP1/Base → starting JP1/Base → starting JP1/IM - Manager. If failover occurs while the parameter is set to `cold`, the system cannot acquire JP1 events that occur during the period of stopping JP1/IM - Manager → stopping JP1/Base and during the period of starting JP1/Base → starting JP1/IM - Manager. Therefore, if you leave the parameter set to `cold`, some JP1 events that are subject to generation processing might be missed.

## ◆ Correlation event generation definition file

### Format

```
VERSION={1 | 2}

#comment-line
[generation-condition-name]
TARGET=filtering-condition-for-the-correlation-target-range
CON=event-condition
TIMEOUT=timeout-period
TYPE=event-correlation-type
SAME_ATTRIBUTE=duplicate-attribute-value-condition
CORRELATION_NUM=maximum-correlation-number
SUCCESS_EVENT=correlation-approval-event
FAIL_EVENT=correlation-failure-event

[generation-condition-name]
TARGET=filtering-condition-for-the-correlation-target-range
CON=event-condition
TIMEOUT=timeout-period
TYPE=event-correlation-type
SAME_ATTRIBUTE=duplicate-attribute-value-condition
CORRELATION_NUM=maximum-correlation-number
SUCCESS_EVENT=correlation-approval-event
FAIL_EVENT=correlation-failure-event
:
```

### File

Use any file. However, the following limitations apply:

- The extension must be `.conf`.
- The file name can consist of only alphanumeric characters and the underscore (`_`).

### Storage directory

In Windows

Any folder

In UNIX

Any directory

### Description

This file defines JP1 event conditions that result in generation of correlation events and the correlation events that are generated when the JP1 event conditions are satisfied. Use the language encoding that is used by JP1/IM - Manager to specify this file.

### When the definitions are applied

The definitions take effect after the correlation event generation definitions are applied by the `jcoegschange` command.

## Information that is specified

VERSION={1 | 2}

Specifies the version of the correlation event generation definition file.

Specify either 1 or 2.

If you specify 1, none of the parameters listed below can be specified. To specify all the parameters described here, specify 2 in the VERSION parameter.

Table 2–32: Parameters that cannot be specified

| Version | Parameter       |
|---------|-----------------|
| 1       | TARGET          |
|         | SAME_ATTRIBUTE  |
|         | CORRELATION_NUM |
| 2       | None            |

Any zeros that are specified preceding the value are ignored. For example, VERSION=0001 is the same as VERSION=1. If this parameter is omitted, VERSION=1 is assumed.

If the specified value is neither 1 nor 2, a definition error results. Specifying VERSION more than once also results in a definition error.

### #comment-line

A line beginning with a hash mark (#) is treated as a comment.

### [generation-condition-name]

This is the start tag for a definition block that defines a correlation event generation condition. The information from the [generation-condition-name] tag to the information immediately before the next [generation-condition-name] tag constitutes one definition block. This tag cannot be omitted. You can define a maximum of 1,000 correlation event generation conditions. If more than 1,000 correlation event generation conditions are defined, a definition error occurs.

You must enclose the generation condition name in square brackets ([ ]). The generation condition name can consist of from 1 to 32 alphanumeric characters, the hyphen (-), underscore (\_), and forward slash (/).

This name is case sensitive. For example, [JP1\_HAKKOUZYOUKEN] is treated as being different from [jp1\_hakkouzyouken].

Each generation condition name specified in the correlation event generation definition file must be unique. If the same generation condition name is specified more than once, the first name specified in the file is effective. A generation condition name cannot begin with IM\_ (whether upper- or lowercase letters are used). If such a name is specified, a definition error occurs.

If you wish to specify a comment immediately following [generation-condition-name], use the format [generation-condition-name] #comment-on-generation-condition.

### TARGET=filtering-condition-for-the-correlation-target-range

Specifies a filtering condition to narrow the range of JP1 events that are to be subject to generation of correlation events. If this parameter is omitted, all JP1 events that are acquired are subject to correlation event generation processing.

You can specify only one filtering condition for the correlation target range for each correlation event generation condition. If multiple filtering conditions are specified, a definition error results.

The following is the format:

- TARGET=event-attribute-condition-1 [ , event-attribute-condition-2 . . . ]

Separate multiple event attribute conditions with the comma ( , ). When multiple event attribute conditions are specified, it is assumed that they are connected with the AND condition, in which case the condition is satisfied only when a JP1 event that satisfies all the specified event attribute conditions is issued.

Specify an event attribute condition in the following format:

*attribute-name comparison-condition attribute-value*

The following table lists and describes the items that can be set for an event attribute condition.

Table 2–33: Items to be set for an event attribute condition

| No. | Item                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <i>attribute-name</i>       | <p>Specifies a JP1 event basic or extended attribute. Prefix a basic attribute with B . and an extended attribute with E . . For example, to specify a message, specify B . MESSAGE.</p> <p>If you specify an extended attribute, express the character string that follows E . using from 1 to 32 bytes of characters. The following rules apply:</p> <ul style="list-style-type: none"> <li>• The character string must begin with an uppercase letter.</li> <li>• The character string beginning with byte 2 must be expressed using uppercase alphanumeric characters and the underscore ( _ ).</li> </ul> <p>For details about the specifiable attribute names, see <a href="#">Table 2-34 List of attribute names that can be specified in the filtering condition for the correlation target range</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 2   | <i>comparison-condition</i> | <p>Specifies a comparison condition. The supported comparison conditions and their meanings are listed below. If any other comparison condition is used, a definition error results.</p> <ul style="list-style-type: none"> <li>• ==: Match</li> <li>• !=: Does not match</li> <li>• ^=: First characters</li> <li>• &gt;=: Is contained</li> <li>• &lt;=: Is not contained</li> <li>• *=: Regular expression</li> </ul> <p>Note: For details about regular expressions, see <a href="#">Appendix G. Regular Expressions</a> in the <i>JP1/Integrated Management 3 - Manager Overview and System Design Guide</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 3   | <i>attribute-value</i>      | <p>Specifies the value to be compared. You can specify a character string with a maximum of 2,048 bytes (1,023 bytes for JP1/IM - Manager version 09-10 or earlier) for an attribute value. If the value exceeds 2,048 bytes (1,023 bytes for JP1/IM - Manager version 09-10 or earlier), the definition is not valid.</p> <p>When specifying multiple event attribute conditions, you can specify a maximum of 2,305 bytes (1,280 bytes for JP1/IM - Manager version 09-10 or earlier) for the total of the attribute values for all conditions. If the value exceeds 2,305 bytes (1,280 bytes for JP1/IM - Manager version 09-10 or earlier), the definition is not valid.</p> <p>For example, if five event attribute conditions are specified, the total of these attributes must be equal to or smaller than 2,305 bytes (1,280 bytes for JP1/IM - Manager version 09-10 or earlier).</p> <p>Separate multiple attribute values with the semicolon ( ; ). Any number of consecutive semicolons between attribute values is treated as a single semicolon ( ; ). For example, B . ID==A ; ; ; B is treated as B . ID==A ; B.</p> <p>Example: If E . xxx==A ; B is specified, the condition is satisfied when E . xxx matches A or B.</p> <p>To use a comma ( , ) or semicolon ( ; ) as an attribute value, or use a space on each end of an attribute value, enclose the part you want to use as an attribute value in double quotation marks ( " ).</p> <p>To specify a double-quotation mark ( " ) or a backslash sign ( \ ) in an attribute value, prefix it with a backslash sign ( \ ).</p> |

- If you specify multiple attribute values for a single attribute name, the condition is satisfied as shown in the following examples:

Example 1: If E . xxx==A ; B is specified, the condition is satisfied when E . xxx matches A or B.

Example 2: If `E.xxx!=A;B` is specified, the condition is satisfied when `E.xxx` matches neither A nor B.

Example 3: If `E.xxx^=A;B` is specified, the condition is satisfied when `E.xxx` begins with A or B.

Example 4: If `E.xxx>=A;B` is specified, the condition is satisfied when `E.xxx` contains either A or B.

Example 5: If `E.xxx<=A;B` is specified, the condition is satisfied when `E.xxx` contains neither A nor B.

Example 6: If `E.xxx*=A;B` is specified, the condition is satisfied when `E.xxx` matches the regular expression of either A or B.

- Be careful about specifying the same attribute name more than once in the same attribute condition. The following combinations result in a definition error:
  - A combination that never matches
    - The message (`B.MESSAGE`) begins with `KAVB` and does not include `KAVB`.
  - Redundant combinations
    - The message (`B.MESSAGE`) begins with `KAVB` and contains `KAVB`.
- The system ignores any space (space and ASCII codes from `0x01` to `0x1F`) between an attribute name, a comparison condition, and an attribute value, at both ends of an attribute value separated by a semicolon, and at both ends of an event attribute condition.  
 Example: The message matches `KAJVxxx-IΔExecuted` or `Error`.  
 A space is ignored if it is specified at the location of `Δ` below:  
`ΔB.MESSAGEΔ==Δ"KAJVxxx-IΔExecuted";ΔErrorΔ`  
 The following specifications are the same as the above example:  
`B.MESSAGE==KAJVxxx-IΔExecuted;Error`  
`B.MESSAGE=="KAJVxxx-IΔExecuted";Error`
- If you specify the event ID (`B.ID`) as the attribute name, the comparison condition must be a complete match (`==`).

The following table lists the attribute names that can be specified in the filtering condition for the correlation target range.

**Table 2–34: List of attribute names that can be specified in the filtering condition for the correlation target range**

| No. | Attribute name                              | Item                                                               |
|-----|---------------------------------------------|--------------------------------------------------------------------|
| 1   | <code>B.SOURCESERVER</code> <sup>#1</sup>   | Event-issuing server name                                          |
| 2   | <code>B.DESTSERVER</code> <sup>#1</sup>     | Target event server name                                           |
| 3   | <code>B.MESSAGE</code>                      | Message                                                            |
| 4   | <code>B.ID</code>                           | Event ID                                                           |
| 5   | <code>B.REASON</code>                       | Reason for registration                                            |
| 6   | <code>B.USERID</code>                       | Source user ID                                                     |
| 7   | <code>B.GROUPID</code>                      | Source group ID                                                    |
| 8   | <code>B.USERNAME</code>                     | Source user name                                                   |
| 9   | <code>B.GROUPNAME</code>                    | Source group name                                                  |
| 10  | <code>E.JP1_SOURCEHOST</code> <sup>#1</sup> | Event source host name                                             |
| 11  | <code>E.xxxxxxx</code> <sup>#2</sup>        | Extended attribute (common information, user-specific information) |

#1

If the integrated monitoring database and the IM Configuration Management database are enabled, the business group name can be specified in a path format.

If the integrated monitoring database and the IM Configuration Management database are disabled, a business group name specified in a path format is treated as a host name.

If the `-ignorecasehost` option of the `jcoimdef` command is set to ON, and a comparison keyword other than Regular expression is selected, the character string is no longer case sensitive.

#2

You can also specify a JP1 product-specific extended attribute. For example, the program-specific extended attribute for the JP1/AJS job execution host is `E.C0`. For details about the product-specific extended attributes, consult the documentation for the products that issue JP1 events.

#### CON=event-condition

Defines the targets of correlation event generation processing or a condition for JP1 events that are to be excluded as targets. You can specify multiple event conditions. There must be at least one definition in each correlation event generation condition. You can define a maximum of 10 event conditions. If no event condition is defined or the specified definition is invalid, a definition error results.

The following is the specification format:

```
CON={NOT| [CID:n] }, event-attribute-condition-1 [, event-attribute-condition-2 [, event-attribute-condition-3 ...] ]
```

If you specify multiple event attribute conditions, separate them with the comma (,). When multiple event attribute conditions are specified, they are assumed to be connected with the AND condition, in which case the condition is satisfied only when a JP1 event that satisfies all the specified event attribute conditions is issued.

The following table lists and describes the items to be set for the event condition.

Table 2–35: Items to be set for the event condition

| No. | Item                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | NOT                        | Specifies that JP1 events are to be excluded as targets of correlation event generation processing.<br>When you specify NOT as an event condition, that condition is applied first, regardless of the sequence in which the event conditions (CON statements) are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2   | CID:n                      | Specifies an ID for the condition. Specify this item to use a variable to pass the correlation source event information to another parameter (SAME_ATTRIBUTE, SUCCESS_EVENT). The permitted values are the integers in the range from 1 to 999.<br>For example, if the correlation source event consists of multiple JP1 events and the <code>\$EVn_B.MESSAGE</code> variable is specified in the SUCCESS_EVENT parameter, message information for the correlation source event can be passed to the correlation event.<br>If this parameter is omitted, information cannot be passed to another parameter. If the specified value is preceded by zeros or the same CID is specified more than once, a definition error results.                                                  |
| 3   | event -attribute-condition | Specifies the event attribute condition in the following format:<br>Format:<br><i>attribute-name comparison-condition attribute-value</i><br><i>attribute-name</i><br>Specifies a JP1 event basic or extended attribute.<br>Prefix a basic attribute with <code>B.</code> and an extended attribute with <code>E.</code><br>For example, to specify the message, specify <code>B.MESSAGE</code> .<br>If you specify an extended attribute, express the character string that follows <code>E.</code> using from 1 to 32 bytes of characters. The following rules apply:<br>The character string must begin with an uppercase letter.<br>The character string beginning in byte 2 must be expressed using uppercase alphanumeric characters and the underscore ( <code>_</code> ). |

| No. | Item | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |      | <p>For details about basic and extended attributes, see <a href="#">3.1 Attributes of JP1 events</a>. To specify a product-specific extended attribute, consult the documentation for that product.</p> <p>If you specify product-specific extended attributes, consult the documentation for the products that issue the JP1 events.</p> <p>Note that you cannot specify the source IP address (SOURCEIPADDR).</p> <p><i>comparison-condition and attribute value</i></p> <p>The rules for specifying the comparison condition and attribute value are the same as for specifying the event attribute condition in TARGET.</p> <p>See <a href="#">Table 2-33 Items to be set for an event attribute condition</a> and the information following the table.</p> |

TIMEOUT=*timeout-period*

Specifies the timeout period for the correlation event generation condition. The permitted value range is from 1 to 86,400 (seconds). If this parameter is omitted, 60 seconds is assumed.

TYPE=*event-correlation-type*

Specifies the event correlation type.

The three event correlation types that can be specified are `sequence`, `combination`, and `threshold`, which are explained below:

- `sequence`  
The correlation event generation condition is satisfied if the JP1 events that satisfy the defined event condition are issued in the order defined.
- `combination`  
The correlation event generation condition is satisfied if a JP1 event that satisfies the combination of defined event conditions is issued regardless of the sequence.
- `threshold:n`  
The correlation event generation condition is satisfied if the number of JP1 events that satisfy the defined event condition reaches the threshold. If multiple event conditions are defined, the correlation event generation condition is satisfied if the total number of JP1 events that satisfy any of the defined conditions reaches the threshold.  
The value permitted for the threshold is from 1 to 100 (count). For example, if the threshold is 10, specify as follows:  
`threshold:10`

This parameter is not case sensitive. If the event correlation type is omitted, `combination` is assumed.

SAME\_ATTRIBUTE=*duplicate-attribute-value-condition*

Specifies the duplicate attribute value condition.

Define this parameter to group the JP1 events (correlation source events) that satisfy the event condition for an attribute value and to generate a correlation event for the group.

You can define a maximum of 3 duplicate attribute value conditions per correlation event generation condition. This parameter is optional.

The following shows the format:

```
- SAME_ATTRIBUTE=attribute-name | { $EVn_attribute-name | $EVn_ENVo } [ , { $EVn_attribute-name | $EVn_ENVo } ... ]
```

The following table lists and describes the items to be set for the duplicate attribute value condition.

Table 2–36: Items to be set for the duplicate attribute value condition

| No. | Item                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <i>attribute-name</i>                    | <p>Specifies a JP1 event basic or extended attribute.</p> <p>The attribute value of the correlation source event that corresponds to the attribute name specified here becomes the grouping key.</p> <p>You can specify only one <i>attribute-name</i> per <i>duplicate-attribute-value-condition</i>.</p> <p>Prefix a basic attribute with B . and an extended attribute with E . If you specify an extended attribute, express the character string that follows E . using from 1 to 32 bytes of characters. The following rules apply:</p> <ul style="list-style-type: none"> <li>• The character string must begin with an uppercase letter.</li> <li>• The character string beginning in byte 2 must be expressed as uppercase alphanumeric characters and the underscore (_).</li> </ul> <p>For details about the specifiable attribute names, see <a href="#">Table 2-37 List of attribute names that can be specified in the duplicate attribute value condition</a>.</p> |
| 2   | Variable<br>\$EVn_ <i>attribute-name</i> | <p>Specify this parameter if the attribute value to be used as the grouping key belongs to an attribute that varies for each correlation source event.</p> <p>For example, specify this parameter to use attribute A ' of correlation source event A and attribute B ' of correlation source event B as the grouping key.</p> <p>You can specify a maximum total of 10 \$EVn_<i>attribute-name</i> and \$EVn_ENVo parameters per duplicate attribute value condition.</p> <p>For details, see <a href="#">(1)(a) Using an attribute value of the correlation source event as the duplicate attribute value condition</a>.</p>                                                                                                                                                                                                                                                                                                                                                     |
| 3   | Variable<br>\$EVn_ENVo                   | <p>Specify this parameter to use part of the attribute value of a correlation source event as the duplicate attribute value condition.</p> <p>For example, specify this parameter to use part of the message (B . MESSAGE) as the grouping key.</p> <p>You can specify a maximum total of 10 \$EVn_ENVo and \$EVn_<i>attribute-name</i> parameters per duplicate attribute value condition.</p> <p>For details, see <a href="#">(1)(b) Using part of an attribute value of the correlation source event as the duplicate attribute value condition</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |

- The attribute name and the value that is replaced with a variable (an attribute value or part of an attribute value) are case sensitive. Only values that perfect matches are able to be a duplicate attribute value condition.
- If the attribute name and the value that is replaced with a variable (attribute value or part of an attribute value) are not in the correlation source event, they are replaced with the null character (0 byte). This means that the null character is used as the grouping key. If this occurs, the following character string is output to the correlation event generation history file:

```
A JP1 event that matches the correlation event generation condition
occurred and correlation event generation processing started, but the
event attribute defined in that attribute value condition was not
found in the JP1 event. (generation-condition-name (generation-processing-number) serial-
number attribute-name)
```

- If you specify SAME\_ATTRIBUTE=*duplicate-attribute-value-condition* more than once, a correlation event is generated for each duplicate attribute value condition.

For example, to issue a correlation event for each host name (B . SOURCESERVER) and user name (B . USERNAME), define as follows:

```
:
SAME_ATTRIBUTE=B.SOURCESERVER
SAME_ATTRIBUTE=B.USERNAME
:
```

- If you specify multiple variables in the duplicate attribute value condition, separate them with the comma ( , ). A correlation event is generated for each attribute value that is replaced with a variable.
- The system ignores any space (space and ASCII codes from 0x01 to 0x1F) between an attribute name and a variable (\$EVn\_attribute-name, \$EVn\_ENVo) and at both ends of a duplicate attribute value condition (Δ in the following example):

Example:

ΔSAME\_ATTRIBUTEΔ=Δ\$EV1\_ENV1Δ, Δ\$EV2\_ENV2Δ

The following table lists the attribute names that can be specified in the duplicate attribute value condition

**Table 2–37: List of attribute names that can be specified in the duplicate attribute value condition**

| No. | Attribute name | Item                                                               |
|-----|----------------|--------------------------------------------------------------------|
| 1   | B.SOURCESERVER | Event-issuing server name                                          |
| 2   | B.DESTSERVER   | Target event server name                                           |
| 3   | B.MESSAGE      | Message                                                            |
| 4   | B.ID           | Event ID                                                           |
| 5   | B.REASON       | Reason for registration                                            |
| 6   | B.USERID       | Source user ID                                                     |
| 7   | B.GROUPID      | Source group ID                                                    |
| 8   | B.USERNAME     | Source user name                                                   |
| 9   | B.GROUPNAME    | Source group name                                                  |
| 10  | E. ....#       | Extended attribute (common information, user-specific information) |

#

You can also specify a JP1 product-specific extended attribute. For example, the product-specific extended attribute for the JP1/AJS job execution host is E.C0. For details about the product-specific extended attributes, consult the documentation for the products that issue JP1 events.

**CORRELATION\_NUM=maximum-correlation-number**

Specifies the maximum number of JP1 event sets that can be held by the correlation event generation condition. Only one maximum correlation number can be defined for a single correlation event generation condition.

The permitted value range is from 1 to 1,024 (sets). If this parameter is omitted, 10 sets is assumed.

*Note:*

It is not recommended to specify CORRELATION\_NUM for many correlation event generation conditions and a large value for the maximum correlation number.

Doing so will increase the number of JP1 event sets that need to be processed concurrently by the Event Generation Service, and result in an increase in the amount of memory required and a reduction in processing speed.

The maximum number of JP1 event sets that can be issued concurrently by all correlation event generation conditions is 20,000 sets. When 20,000 sets have been issued concurrently, a JP1 event (event ID: 00003F28) is output; until the number of sets drops below 20,000, no more processing is performed even if new JP1 events that satisfy the event conditions are issued.

**SUCCESS\_EVENT=correlation-approval-event**

Defines the JP1 event (correlation event) that is to be issued when the correlation event generation condition results in correlation approval. Only one correlation approval event can be defined for a correlation event generation condition.

For details about the conditions that result in correlation approval, see *4.3.6(1) Generation condition satisfied in the JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

If you have defined `FAIL_EVENT=correlation-failure-event` in the correlation event generation condition, you can omit this parameter. When this parameter is omitted, no correlation approval event is issued, even when the correlation event generation condition results in correlation approval.

Specify the correlation approval event in the following format:

*attribute-name : attribute-value*

The following describes each item.

#### *attribute-name*

Specifies a JP1 event basic or extended attribute (correlation source event). Prefix a basic attribute with `B.` and an extended attribute with `E.` If you specify an extended attribute, express the character string that follows `E.` using from 1 to 32 bytes of characters. The following rules apply:

- The character string must begin with an uppercase letter.
- The character string beginning in byte 2 must be expressed as uppercase alphanumeric characters and the underscore (`_`).

You can specify any value for the following attributes:

- Event ID (`B.ID`)
- Message (`B.MESSAGE`)
- Extended attributes, except for those listed in the table below.

**Table 2–38: Extended attributes for which a value cannot be specified**

| Attribute type            | Item                                        | Attribute name                                        | Description                                                                                                                                                                                                 |
|---------------------------|---------------------------------------------|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Common information        | Product name                                | <code>E.PRODUCT_NAME</code>                           | <code>/HITACHI/JP1/IM/GENERATE_EVENT</code>                                                                                                                                                                 |
|                           | Object type                                 | <code>E.OBJECT_TYPE</code>                            | <code>SERVICE</code>                                                                                                                                                                                        |
|                           | Object name                                 | <code>E.OBJECT_NAME</code>                            | <code>EGS</code>                                                                                                                                                                                            |
|                           | Occurrence                                  | <code>E.OCCURRENCE</code>                             | <code>SUCCESS</code>                                                                                                                                                                                        |
| User-specific information | Relation Event serial number                | <code>E.JP1_GENERATE_SOURCE_SEQNO</code>              | Stores the serial numbers of the correlation source events separated by the space:<br><i>serial-number-1 serial-number-2 serial-number-3 . . . serial-number-n</i><br>The maximum value of <i>n</i> is 100. |
|                           | Correlation event generation condition name | <code>E.JP1_GENERATE_NAME</code>                      | Name of correlation event generation condition that is satisfied                                                                                                                                            |
|                           | Reserved word                               | Extended attribute beginning with <code>E.JP1_</code> | Extended attribute reserved by JP1/IM - Manager (other than the event source host name ( <code>E.JP1_SOURCEHOST</code> ))                                                                                   |

If you want to pass the attribute value of a correlation source event to the correlation event, specify a variable. Specify *correlation-approval-event* in the following format:

*attribute-name : \$EVn\_attribute-name*

In this case, specify the correlation source event to be inherited by `CID` of the event condition and then specify the value of `CID` in *n*. Specify a variable to the right of the colon.

For details, see *(2)(a) Passing an attribute value of the correlation source event to an attribute value of the correlation event*.

If you want to specify a threshold (`threshold`) as the event correlation type and pass an attribute value of the correlation source event to the correlation event, specify *correlation-approval-event* in the following format:

*attribute-name*: \$EVn\_m\_attribute-name

In this case, specify the correlation source event to be inherited by CID and then specify in *n* the value of CID. Specify a variable to the right of the colon. Also, specify in *m* the location of the correlation source event whose attribute value is to be passed.

For details, see (2)(b) *Passing an attribute value of the correlation source event to an attribute value of the correlation event (when the event correlation type is threshold)*.

If you wish to pass a portion of an attribute value of the correlation source event to the correlation event, specify the \$EVn\_ENVo variable. Use a regular expression to specify the event condition and enclose the portion of the attribute value to be acquired in parentheses.

Specify *correlation-approval-event* in the following format:

*attribute-name*: \$EVn\_ENVo

In this case, specify the correlation source event to be passed to CID and specify the value of CID in *n*. In *o* of ENVo, specify the acquisition order.

For details, see (2)(c) *Passing part of an attribute value of the correlation source event to the correlation event*.

For details about basic and extended attributes, see 3.1 *Attributes of JP1 events*. If you specify product-specific extended attributes, consult the documentation for the products that issue JP1 events.

- You can specify multiple items in *correlation source event* by separating them with the comma ( , ).
- Make sure that you specify the event ID of a basic attribute (B.ID). The permitted range of event IDs is from 0 to 1FFF and from 7FFF8000 to 7FFFFFFF. If the event ID is not specified, 0 is set as the event ID.
- The maximum length of a single correlation approval event is 8,192 bytes. The maximum length of B.MESSAGE is 1,023 bytes. These maximum lengths include spaces but do not include linefeed codes.
- The system ignores any space (space and ASCII codes from 0x01 to 0x1F) between an attribute name and an attribute value and at both ends of SUCCESS\_EVENT=*correlation-approval-event* (the space is represented by Δ in the following example).

Example:

ΔSUCCESS\_EVENTΔ=ΔB.IDΔ:Δ1Δ

- To use a comma ( , ) or a space in an attribute value, enclose it in double-quotation marks (").
- To specify a double-quotation mark (") or a backslash (\), prefix it with a backslash (\) so that the value becomes \" or \\\.

To restore a special character (^ \$ . \* + ? | ( ) { } [ ] \) to its original meaning, prefix it with two backslash signs so that the value becomes \\special-character.

For example, to treat \$ as a normal character, specify it as \\\$. Also, to give \ its original meaning, specify \\\.

- If you omit an attribute value, nothing is set when a correlation event is generated. If you omit the attribute value of an attribute name (B.ID), 0 is set.
- To specify a setting following the \$EVn\_attribute-name variable, specify a space (indicated by Δ in the example below) after the variable.

Example:

SUCCESS\_EVENT=B.MESSAGE:"\$EVn\_B.IDΔ\$EVn\_B.TIMEΔ..."

- If you use a variable and there is no matching attribute name, the variable is replaced with a space. If the variable would be replaced when the correlation event is generated with an attribute value that exceeds the permitted maximum value, the correlation event is not generated.
- Up to 94 extended attributes can be specified.

FAIL\_EVENT=*correlation-failure-event*

Defines a JP1 event (correlation event) that is to be issued when the correlation event generation condition results in a correlation failure. You can define only one correlation failure event per correlation event generation condition. For details about the conditions that result in a correlation failure, see 4.3.6(2) *Generation condition fails* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

If you have specified SUCCESS\_EVENT=*correlation-approval-event* in the correlation event generation conditions, you can omit this parameter. When this parameter is omitted, no correlation failure event is issued even if a correlation event generation condition results in a failure.

Specify *correlation-failure-event* in the same format as used for a correlation approval event. For details, see *SUCCESS\_EVENT=correlation-approval-event*.

## (1) Using a variable in the duplicate attribute value condition (SAME\_ATTRIBUTE)

This subsection describes how to use a variable (\$EVn or \$EVn\_ENVo) in the duplicate attribute value condition (SAME\_ATTRIBUTE).

### (a) Using an attribute value of the correlation source event as the duplicate attribute value condition

To use an attribute value of the correlation source event as the duplicate attribute value condition, use the \$EVn\_attribute-name variable. The format is as follows:

- SAME\_ATTRIBUTE=\$EVn\_attribute-name

For *n*, specify the value that corresponds to the condition ID (CID) of the event condition. A value from 1 to 999 can be specified for the condition ID.

For *attribute-name*, specify the attribute name that is to be used as the grouping key. For details about the specifiable attributes names, see *Table 2-37 List of attribute names that can be specified in the duplicate attribute value condition*.

For example, the following definition associates JP1 events that have attribute values whose host information is different, such as a JP1 event of Windows log trapping (event ID: 00003A71) and a JP1 event issued by JP1/AJS (event ID: 00004107), and generates a correlation event for each host:

```
CON=CID:1,B.ID==3A71,E.A0==host1;host2
CON=CID:2,B.ID==4107,E.C0==host1;host2
:
SAME_ATTRIBUTE=$EV1_E.A0,$EV2_E.C0
:
```

### (b) Using part of an attribute value of the correlation source event as the duplicate attribute value condition

To use part of the attribute value of a correlation source event as the duplicate attribute value condition, use the \$EVn\_ENVo variable. The format is as follows:

- SAME\_ATTRIBUTE=\$EVn\_ENVo

When you specify \$EVn\_ENVo, use a regular expression (\*=) to specify the event condition and enclose the part of the attribute value that is to be acquired in parentheses. For *n*, specify the value that corresponds to the condition ID (CID) of the event condition. A value from 1 to 999 can be specified for the condition ID.

In *o* of ENVo, specify the acquisition order. The acquisition order is based on the order of the parentheses in the right-hand term of the event condition, counting the pairs of parentheses from left to right. A value from 1 to 9 can be specified for the acquisition order.

The following figure shows the correspondence between the event condition (CON) and the part that is acquired by \$EVn\_ENVo.

Figure 2–3: Correspondence between the event condition (CON) and the part that is acquired by \$EVn\_ENVo

If there are multiple event attribute conditions that specify regular expressions in a single event condition (CON), count the pairs of parentheses from left to right and set in *o* the order of the pair enclosing the attribute value that is to be acquired.

For example, if you want to issue correlation events for each event that has the same host name in the message in the correlation source event, define as follows:

```
CON=CID:1, B.ID==1001, B.MESSAGE*=.*HOST=(.*\\)
TYPE=threshold:5
SAME_ATTRIBUTE=$EV1_ENV1
:
```

## (2) Using a variable in the correlation approval event (SUCCESS\_EVENT)

To pass an attribute value of the correlation source event to the correlation event, use a variable in the correlation approval event (SUCCESS\_EVENT).

- (a) Passing an attribute value of the correlation source event to an attribute value of the correlation event
 

To pass an attribute value of the correlation source event to an attribute value of the correlation event, use the \$EVn\_attribute-name variable. The format is as follows:

- SUCCESS\_EVENT=attribute-name:\$EVn\_attribute-name

For *n*, specify the condition ID (CID) that was specified in the event condition. For the right-hand *attribute-name*, specify the attribute that is to be passed from the correlation source event. Note that if the event ID (B.ID) is specified in the left-hand *attribute-name*, an attribute value of the correlation source event cannot be passed.

The following table lists the attribute names that can be specified in the variable.

Table 2–39: List of attribute names that can be specified in the variable

| No. | Attribute name | Item              | Format                                                  |
|-----|----------------|-------------------|---------------------------------------------------------|
| 1   | B.SEQNO        | Serial number     | Numeric value                                           |
| 2   | B.ID           | Event ID          | <i>basic-part:extended-part</i> in hexadecimal notation |
| 3   | B.PROCESSID    | Source process ID | Numeric value                                           |

| No. | Attribute name        | Item                      | Format                               |
|-----|-----------------------|---------------------------|--------------------------------------|
| 4   | B.TIME                | Registered time           | YYYY/MM/DD<br>hh:mm:ss <sup>#1</sup> |
| 5   | B.ARRIVEDTIME         | Arrived time              | YYYY/MM/DD<br>hh:mm:ss <sup>#1</sup> |
| 6   | B.REASON              | Reason for registration   | Character string                     |
| 7   | B.USERID              | Source user ID            | Numeric value                        |
| 8   | B.GROUPID             | Source group ID           | Numeric value                        |
| 9   | B.USERNAME            | Source user name          | Character string                     |
| 10  | B.GROUPNAME           | Source group name         | Character string                     |

| 12  | B.DESTSERVER          | Target event server name  | Character string                     |
| 13  | B.SOURCESEQNO         | Source serial number      | Numeric value                        |
| 14  | B.MESSAGE             | Message                   | Character string                     |
| 15  | E.SEVERITY            | Event level               | Character string                     |
| 16  | E.USER_NAME           | User name                 | Character string                     |
| 17  | E.PRODUCT_NAME        | Product name              | Character string                     |
| 18  | E.OBJECT_TYPE         | Object type               | Character string                     |
| 19  | E.OBJECT_NAME         | Object name               | Character string                     |
| 20  | E.ROOT_OBJECT_TYPE    | Root object type          | Character string                     |
| 21  | E.ROOT_OBJECT_NAME    | Root object name          | Character string                     |
| 22  | E.OBJECT_ID           | Object ID                 | Character string                     |
| 23  | E.OCCURRENCE          | Occurrence                | Character string                     |
| 24  | E.START_TIME          | Start time                | YYYY/MM/DD<br>hh:mm:ss <sup>#1</sup> |
| 25  | E.END_TIME            | End time                  | YYYY/MM/DD<br>hh:mm:ss <sup>#1</sup> |
| 26  | E.xxxxx <sup>#2</sup> | Other extended attribute  | Character string                     |

#1

This value is obtained by converting the JP1 event's time in GMT to the time zone of JP1/IM - Manager.

#2

You can also specify a JP1 product-specific extended attribute. For example, the program-specific extended attribute for the JP1/AJS job execution host is E.C0. For details about the product-specific extended attributes, consult the documentation for the products that issue JP1 events.

The following figure shows an example of passing an attribute value from the correlation source event.

**Figure 2–4: Example of using a variable to pass an attribute value to the correlation approval event**

Contents of JP1 events that are issued (example)

- JP1 event issued by JP1/AJS2  
SEVERITY = Error  
MESSAGE = An error occurred in job A.
- JP1 event issued by JP1/Base  
SEVERITY = Error  
MESSAGE = hostA has stopped.

Definition in the correlation event generation definition file

```
CON=CID:1,E.SEVERITY==Error,E.PRODUCT_NAME>=HITACHI/JP1/AJS2
CON=CID:5,E.SEVERITY==Error,E.PRODUCT_NAME>=HITACHI/JP1/Base1

SUCCESS_EVENT=E.SEVERITY: $EV1_E.SEVERITY ,B.MESSAGE: $EV1_B.MESSAGE Δ $EV5_B.MESSAGE
```

*Italics indicate the attribute values that are passed.*

Matching of JP1 events and the correlation event generation definition

- JP1 event issued by JP1/AJS2

```
SEVERITY = Error
MESSAGE = An error occurred in job A.
```

- JP1 event issued by JP1/Base

```
SEVERITY = Error
MESSAGE = An application error occurred on hostA.
```

```
CON=CID:1,E.SEVERITY==Error,E.PRODUCT_NAME>=HITACHI/JP1/AJS2
CON=CID:5,E.SEVERITY==Error,E.PRODUCT_NAME>=HITACHI/JP1/Base1

SUCCESS_EVENT=E.SEVERITY: $EV1_E.SEVERITY ,B.MESSAGE: $EV1_B.MESSAGE Δ $EV5_B.MESSAGE
```

Correlation event that is generated:

```
SEVERITY= Error
MESSAGE= An error occurred in job A. An application error occurred on hostA.
```

Legend:

Δ : Single-byte space

In this example, the event levels issued by JP1/AJS and JP1/Base associate the JP1 event for an error, resulting in generation of a correlation event.

This example defines *correlation-approval-event* as follows:

- For the event level, the correlation event passes the event level of the JP1 event issued by JP1/AJS.
- For the message, the correlation event passes the messages for the JP1 events issued by JP1/AJS and JP1/Base.

(b) Passing an attribute value of the correlation source event to an attribute value of the correlation event (when the event correlation type is threshold)

This subsection describes how to define a correlation approval event using a variable when the event correlation type is threshold.

When the event correlation type is threshold, multiple JP1 events can satisfy a single event condition (CON). The following figure shows an example.

Figure 2–5: When the event correlation type is threshold

Example:  
Generate a correlation event if a JP1 event containing `Login error` in the message is issued three times.

| Issued JP1 events (example) |                                                                                  | Issuance order |
|-----------------------------|----------------------------------------------------------------------------------|----------------|
| Event 1                     | Message: Login error user ID (10000000) does not have permissions.               | ...1           |
| Event 2                     | Message: Login error (second time) user ID (10000000) does not have permissions. | ...2           |
| Event 3                     | Message: Login error (third time) user ID (10000000) is an unauthorized user.    | ...3           |

Definition in the correlation event generation definition file

```
CON=CID:1,B.MESSAGE*="Login△error"  
TYPE=threshold:3  
SUCCESS_EVENT=B.ID:A00,△E.SEVERITY:Error,△B.MESSAGE:$EV1_B.MESSAGE
```

*Italics indicate the attribute values that are passed.*

Because three JP1 events match *\$EV1\_B.MESSAGE*, the messages that are passed (event 1, event 2, or event 3) must be specified.

Legend:  
△ : Single-byte space

As shown in this figure, three JP1 events (Event 1, Event 2, and Event 3) match *\$EV1\_B.MESSAGE*. Therefore, the message to be passed must be specified.

In this case, specify the correlation approval event in the following format:

- *SUCCESS\_EVENT=attribute-name:\$EVn\_m\_attribute-name*

For *n*, specify the condition ID (CID) that was specified in the event condition as described above. For the right-hand *attribute-name*, specify the attribute that is to be passed from the correlation source event. Note that if the event ID (B.ID) is specified in the left-hand *attribute-name*, an attribute value of the correlation source event cannot be passed.

In *m*, specify the order in which the JP1 events (correlation source events) are processed. To pass the attribute value of the third JP1 event that was processed, specify 3 in *m*. If the value of *m* is greater than the value specified in the threshold (*threshold:n*), a definition error results.

The following figure shows an example of passing attribute values when the event correlation type is threshold.

Figure 2–6: Example of passing attribute values when the event correlation type is threshold

You can omit both *n* and *m* in *attribute-name*: `$EVn_m_attribute-name`. The following examples describe how attribute values are passed when *n* and *m* are omitted.

**Example 1:**  
If a JP1 event containing `Login error` in the message is issued three times, generate a correlation event that receives the message in the correlation source event.

*Definition in the correlation event generation definition file*

```
[ex.1]
CON=CID:1,B.MESSAGE*="Login error"
TYPE=threshold:3
SUCCESS_EVENT=B.ID:A00,E.SEVERITY:Error,B.MESSAGE:setting
```

Table 2–40: Conditions to be satisfied and settings (in Example 1)

| No. | Condition to be satisfied                                                                           | Setting                                                                          |
|-----|-----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| 1   | Pass to the correlation event the message in the first JP1 event that satisfies the event condition | \$EV1_1_B.MESSAGE<br>or \$EV_1_B.MESSAGE                                         |
| 2   | Pass the message in the second JP1 event that satisfies the event condition                         | \$EV1_2_B.MESSAGE<br>or \$EV_2_B.MESSAGE                                         |
| 3   | Pass the message in the third (last) JP1 event that satisfies the event condition                   | \$EV1_3_B.MESSAGE,<br>\$EV1_B.MESSAGE,<br>\$EV_3_B.MESSAGE,<br>or \$EV_B.MESSAGE |

*Example 2:*

If a JP1 event that satisfies either of the conditions listed below is issued 10 times, generate a correlation event that receives the message in the correlation source event.

- Event ID is 100 and the message contains Warning.
- Event ID is 200 and the message contains Warning or Error.

*Definition in the correlation event generation definition file:*

```
[ex.2]
CON=CID:100,B.ID==100,B.MESSAGE*="Warning"
CON=CID:200,B.ID==200,B.MESSAGE*="Warning";"Error"
TYPE=threshold:10
SUCCESS_EVENT=B.ID:B00,E.SEVERITY:Error,B.MESSAGE:setting
```

Table 2–41: Conditions to be satisfied and settings (in Example 2)

| No. | Condition                                                                                                               | Setting                                |
|-----|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| 1   | Pass to the correlation event the message in the first JP1 event that satisfies the event condition (condition ID: 100) | \$EV100_1_B.MESSAGE                    |
| 2   | Pass to the correlation event the message in the fifth JP1 event that satisfies the event condition (condition ID: 100) | \$EV100_5_B.MESSAGE                    |
| 3   | Pass to the correlation event the message in the 10th JP1 event that satisfies the event condition (condition ID: 100)  | \$EV100_10_B.MESSAGE                   |
| 4   | Pass to the correlation event the message in the first JP1 event processed, regardless of the event conditions          | \$EV_1_B.MESSAGE                       |
| 5   | Pass to the correlation event the message in the fifth JP1 event processed, regardless of the event conditions          | \$EV_5_B.MESSAGE                       |
| 6   | Pass to the correlation event the message in the 10th (last) JP1 event processed, regardless of the event conditions    | \$EV_10_B.MESSAGE<br>or \$EV_B.MESSAGE |

The following summarizes the processing:

*When n is omitted:*

If *n* is omitted, only the correlation source event with the order specified in *m* is used for checking the conditions. For example, if 3 is specified in *m*, the attribute value of the third correlation source event processed is passed to the correlation event.

*When m is omitted:*

If *m* is omitted, the last correlation source event processed is the target, regardless of the order. For example, if the threshold is 10, the attribute value of the 10th correlation source event processed is passed.

If *n* is specified, the attribute value of the last correlation source event processed by the event condition is passed.

*When n and m are both omitted:*

If *n* and *m* are both omitted, the last correlation source event processed is the target, regardless of the event conditions or the order of processing.

Note that regardless of whether *n* or *m* is specified, if no (source) JP1 event satisfies the conditions, the variable is replaced with the null character (0 bytes).

(c) Passing part of an attribute value of the correlation source event to the correlation event

To pass part of an attribute value of the correlation source event to the correlation event, use the `$EVn_ENVo` variable.

In this case, use a regular expression (`*`) to specify the event condition and enclose the part of the attribute value that is to be acquired in parentheses.

Specify *correlation-approval-event* in the following format:

`SUCCESS_EVENT=attribute-name:$EVn_ENVo`

Specify the correlation source event to be received by `CID` and specify the value of `CID` in *n*. In *o* of `ENVo`, specify the acquisition order. The following figure shows an example of receiving part of an attribute value.

Figure 2–7: Example of receipt by the correlation approval event when the \$EVn\_ENVo variable is used

Example:

Acquire the error code contained in the message in the issued event and set it in the message that is received by the correlation event.

Issued JP1 event (example)

Event 1 Event level: Error Message: KAx-E Error occurred ErrorCode=1111 2006/11/11/16:10:52

Event 2 Event level: Critical Message: KAx-E Fatal error occurred ErrorCode=2000 2006/11/11/16:12:30

Definition in the correlation event generation definition file

```
CON=CID:1,E.SEVERITY==Error,B.MESSAGE*=ErrorCode=(...).*$
CON=CID:2,E.SEVERITY==Critical,B.MESSAGE*=ErrorCode=(...).*$
SUCCESS_EVENT=B.ID:C00,ΔE.SEVERITY:Alert,
ΔB.MESSAGE: Error code $EVI_ENVIΔ$Error occurred inΔ$EV2_ENVI
```

*Italics indicate the attribute values that are received.*

Matching of JP1 events and the correlation event generation definition

Issued JP1 event (example)

Event 1 Event level: Error Message: KAx-E Error occurred ErrorCode= 1111 2006/11/11/16:10:52

Event 2 Event level: Critical Message: KAx-E Fatal error occurred ErrorCode= 2000 2006/11/11/16:12:30

Definition in the correlation event generation definition file

```
CON=CID:1,E.SEVERITY==Error,B.MESSAGE*=ErrorCode=(...).*$
CON=CID:2,E.SEVERITY==Critical,B.MESSAGE*=ErrorCode=(...).*$
SUCCESS_EVENT=B.ID:C00,ΔE.SEVERITY:Alert,
ΔB.MESSAGE: Error code $EVI_ENVIΔ$Error occurred inΔ$EV2_ENVI
```

Correlation event that is generated

```
ID=C00
SEVERITY= Alert
MESSAGE=Error code 1111 Error occurred in 2000
```

Legend:

Δ : Single-byte space

This example uses parentheses to acquire the right-hand term of ErrorCode= from the correlation source event that is specified by the conditions of condition ID (CID) =1 and condition ID (CID) =2.

If you use the \$EVn\_ENVo variable, when a correlation source event that has an attribute value containing a specific character string is issued, you can generate a correlation event, and then pass the portion of the character string contained in the attribute value to the correlation event.

In this case, specify in o of ENVo the numeric value that determines the parentheses pair that follows the regular expression (\*=) specified in the event conditions. In other words, count parentheses pairs from left to right for the attribute value in the correlation source event that follows the regular expression (\*=) in the event conditions, and then specify in o the location that is to be passed.

The part acquired by \$EVn\_ENVo is the same as when \$EVn\_ENVo is specified in the duplicate attribute value condition. For details, see [Figure 2-3 Correspondence between the event condition \(CON\) and the part that is acquired by \\$EVn\\_ENVo](#).

The example shown below generates a correlation event if a correlation source event with an attribute value that contains a specific character string is issued, and passes part of the character string contained in that attribute value to the correlation event.

**Figure 2–8: Example of passing part of a character string contained in an attribute value to the correlation event**

**Example:**

Acquire part of the message in a correlation source event that has multiple sets of parentheses in the attribute value and then pass it to the correlation event.

**Issued JP1 event (example)**

```
Event   Event level: Error
        Message: KAx-E Error occurred  host=AGENT_A ErrorCode=1111 2006/11/11/16:10:52
```

**Definition in the correlation event generation definition file**

```
CON=CID:1,△E.SEVERITY==Error,△B.MESSAGE*=host=(MANAGER_A△
|AGENT_(A|B|C)).*ErrorCode=(....).*$
SUCCESS_EVENT=B.ID:C00,△E.SEVERITY:Alert,
△B.MESSAGE: Error with error code $EVI_ENV3△ occurred at the host $EVI_ENV1△
```

*Italics indicate the attribute values that are passed.*

**Matching JP1 events and the correlation event generation definition**

**Issued JP1 event (example)**

```
Event   Event level: Error
        Message: KAx-E Error occurred  host=AGENT_A ErrorCode=1111 2006/11/11/16:10:52
```

**Definition in the correlation event generation definition file**

```
CON=CID:1,△E.SEVERITY==Error,△B.MESSAGE*=host=(MANAGER_A△
|AGENT_(A|B|C)).*ErrorCode=(....).*$
SUCCESS_EVENT=B.ID:C00,△E.SEVERITY:Alert,
△B.MESSAGE: Error with error code $EVI_ENV3△ occurred at the host $EVI_ENV1△
```

**Correlation event that is generated**

```
B.ID : C00
E.SEVERITY : Alert
B.MESSAGE : Error with error code 1111 occurred at the host AGENT_A
```

**Legend:**

△ : Single-byte space

This example specifies the definition in such a manner that whenever a correlation source event that satisfies the conditions listed below is generated, an attribute value is passed from it to the correlation event:

- host= is followed by MANAGER\_A, AGENT\_A, AGENT\_B, or AGENT\_C.
- ErrorCode= is followed by a character string of at least 4 characters.#

#

- If the character string consists of more than four characters, only the first four characters are passed. For example, in the case of ErrorCode=12345678, 1234 is passed.

- If the character string consists of fewer than four characters, the necessary number of characters that follow `ErrorCode=` *character-string* are included so that four characters are passed.

For example, in the case of `ErrorCode=1 2006/11/11, 1 20` is passed.

If the character string that follows `ErrorCode=` consists of fewer than 4 characters, no correlation event is generated.

## Example definition

Example 1: Generate a correlation event for any JP1 event whose event level is `Error` or higher:

```
VERSION=2

#Generate a correlation event for any a JP1 event
#whose event level is Error or higher
[filter_over_error]
CON=CID:1,B.ID==1,E.SEVERITY==Error;Critical;Alert;Emergency
SUCCESS_EVENT=E.SEVERITY:Emergency,B.MESSAGE:$EV1_B.MESSAGE
```

Example 2: Generate a correlation event for any JP1 event whose event level is `Error` or higher and for any JP1 event issued by JP1/AJS whose event level is `Error`:

If the following definition is specified and JP1/AJS issues a JP1 event whose event level is `Error`, two correlation events will be generated because the JP1 event satisfies the two correlation event generation conditions `over_error` and `ajs2_over_error`:

```
VERSION=2

#Generate a correlation event for any JP1 event whose
#event level is Error or higher.
[over_error]
CON=CID:1,E.SEVERITY==Error;Critical;Alert;Emergency
SUCCESS_EVENT=E.SEVERITY:Emergency,B.MESSAGE:$EV1_B.MESSAGE

#Generate a correlation event for any JP1 event issued by
#JP1/AJS@ whose event level is Error.
[ajs2_over_error]
CON=CID:1,E.SEVERITY==Error,E.PRODUCT_NAME==/HITACHI/JP1/AJS2
SUCCESS_EVENT=E.SEVERITY:Emergency,B.MESSAGE:$EV1_B.MESSAGE
```

To generate only one correlation event when JP1/AJS issues a JP1 event whose event level is `Error`, specify the first correlation event generation condition as follows:

```
VERSION=2

#Generate a correlation event for any JP1 event whose
#event level is Error or higher.
#Exclude events issued by JP1/AJS2.
[over_error_and_not_ajs2]
CON=NOT,E.SEVERITY==Error,E.PRODUCT_NAME==/HITACHI/JP1/AJS2
CON=CID:1,E.SEVERITY==Error;Critical;Alert;Emergency
SUCCESS_EVENT=E.SEVERITY:Emergency,B.MESSAGE:$EV1_B.MESSAGE

#Generate a correlation event for any JP1 event issued by
#JP1/AJS2 whose event level is Error.
[ajs2_over_error]
```

```
CON=CID:1,E.SEVERITY==Error,E.PRODUCT_NAME==/HITACHI/JP1/AJS2
SUCCESS_EVENT=E.SEVERITY:Emergency,B.MESSAGE:$EV1_B.MESSAGE
```

**Example 3: Define a timeout period:**

```
VERSION=2

[condition]
CON=NOT,E.SEVERITY==Error,E.PRODUCT_NAME==/HITACHI/JP1/AJS2

CON=CID:1,B.ID==1,B.MESSAGE==TEST,E.SEVERITY==Warning
CON=CID:2,B.ID==1,B.MESSAGE==TEST,E.SEVERITY==Error
CON=CID:3,B.ID==1,B.MESSAGE==TEST,E.SEVERITY==Critical

TIMEOUT=10
SUCCESS_EVENT=E.SEVERITY:Emergency,B.MESSAGE:$EV1_B.MESSAGE
```

**Example 4: Generate a single correlation event that combines the messages in JP1 events issued by JP1/AJS2 and JP1/Base and whose event level is Error:**

```
VERSION=2

[cond1]

CON=CID:1,E.SEVERITY==Error,E.PRODUCT_NAME>=HITACHI/JP1/AJS2
CON=CID:5,E.SEVERITY==Error,E.PRODUCT_NAME>=HITACHI/JP1/Base

SUCCESS_EVENT=E.SEVERITY:$EV1_E.SEVERITY,B.MESSAGE:"$EV1_B.MESSAGE $EV5_B.
MESSAGE"
```

**Example 5: Acquire a value by using the \$EVn\_ENVo variable:**

This example acquires the detail code `errorΔcodeΔ=ΔnΔ` that is included in the message and then places it in the message in the correlation event (*n*: any character string; Δ: Space).

```
VERSION=2

[SAMPLE]

CON=CID:100, B.MESSAGE*=(errorΔcodeΔ=.*Δ)
SUCCESS_EVENT=B.ID:100,E.SEVERITY:Emergency,B.MESSAGE: error-information[$
EV100_ENV1Δ]
```

**Example 6: Narrow down the target range for correlation by the host and generate a correlation event for each user with the maximum correlation number set to 20:**

```
VERSION=2

[condition2]
TARGET=B.SOURCESERVER==host1;host2;host3
CON=NOT, E.SEVERITY==Error, E.PRODUCT_NAME==/HITACHI/JP1/AJS2

CON=CID:1, B.ID==1, B.MESSAGE==TEST, E.SEVERITY==Warning
CON=CID:2, B.ID==1, B.MESSAGE==TEST, E.SEVERITY==Error
CON=CID:3, B.ID==1, B.MESSAGE==TEST, E.SEVERITY==Critical

SAME_ATTRIBUTE=E.USERNAME
CORRELATION_NUM=20
```

```
TIMEOUT=10
SUCCESS_EVENT=B.MESSAGE:$EV1_B.MESSAGE
```

## ◆ Correlation event generation environment definition file

### Format

```
[logical-host-name\JP1CONSOLEMANAGER\EVGEN]
"OPERATION_LOG_SIZE"=dword:hexadecimal-value
"OPERATION_LOG_NUM"=dword:hexadecimal-value
```

### File

Use any file.

### Storage directory

In Windows

Any folder

In UNIX

Any directory

### Description

This file defines the size and number of correlation event generation history files.

When this file is updated, the definition information is updated for all processes managed by JP1/IM - Manager.

### When the definitions are applied

The definition takes effect when JP1/IM - Manager is restarted or the `jco_spmd_reload` command is executed after the `jbssetcnf` command has been executed to apply the definition to the common definition information.

### Information that is specified

[*logical-host-name*\JP1CONSOLEMANAGER\EVGEN]

Specifies the key name for the JP1/IM - Manager environment settings.

For *logical-host-name*, specify JP1\_DEFAULT for the physical host and *logical-host-name* for a logical host.

"OPERATION\_LOG\_SIZE"=dword:*hexadecimal-value*

Specifies in hexadecimal notation the size of one correlation event generation history file. The permitted value range is from 00010000 to 06400000 (from 64 kilobytes to 100 megabytes). The default is 00A00000.

"OPERATION\_LOG\_NUM"=dword:*hexadecimal-value*

Specifies in hexadecimal notation the number of correlation event generation history files. The permitted value range is from 00000003 to 00000064 (from 3 to 100 files). The default is 00000003 (3 files).

## How to determine the size and number of correlation event generation history files

If it is necessary to adjust the size and number of correlation event generation history files, estimate the size of the correlation event generation history file required for one day and multiply that value by the number of days the files are to be retained. Set a value that is larger than the estimated value.

For details about the estimation, see the Release Notes for JP1/IM - Manager.

## ◆ Definition file for manually registering incidents (incident.conf)

### Format

```

### File

`incident.conf` (definition file for manually registering incidents)

`incident.conf.model` (model file for the definition file for manually registering incidents)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\incident\

For a logical host:

*shared-folder*\jplcons\conf\console\incident\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/console/incident/

For a logical host:

*shared-directory*/jplcons/conf/console/incident/

### Description

This definition file is used to register a JP1 event in JP1/IM - View as an incident in another product.

### When the definitions are applied

The settings in the definition file for manually registering incidents take effect when the `jco_spmc_reload` command is executed, or when a user logs in to JP1/IM - Manager (Central Console) after restarting JP1/IM - Manager.

## Information that is specified

VERSION=*version-information*

Specify the version of the definition file for manually registering incidents. Specify 3 for *version-information*. If you omit this parameter, or did not specify the value correctly, the SS\_URL and SS\_MODE parameters are ignored. Note that if you specify this parameter more than once, the parameter on the last line is valid.

**Table 2–42: List of parameters that can be specified for the version information and definition file for manually registering incidents**

| Version information | Parameter name    |
|---------------------|-------------------|
| 2                   | SS_URL#           |
| 3                   | SS_URL<br>SS_MODE |

#

This works with SS\_MODE=1.

SS\_MODE={ 1 | 2 | 3 }

Specify the registration mode of an incident. If you want to specify this parameter, specify 3 for the VERSION parameter. If not, this parameter is ignored. You can specify 1, 2, or 3. The following table describes available incident registration modes and when each mode should be used.

**Table 2–43: Incident registration modes and when to use each of them**

| Incident registration mode | Description                                                                                                                                                                                                                                     | When to use                                                                                                                                                                                                                             | Supported version of JP1/IM - Manager, JP1/IM - View, and JP1/Service Support |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| SS_MODE=1                  | Source attributes and their target fields are fixed.                                                                                                                                                                                            | The specification of JP1/IM - Manager 10-00 or earlier must be used for linkage with JP1/Service Support.                                                                                                                               | 09-50 or later                                                                |
| SS_MODE=2                  | <ul style="list-style-type: none"><li>Source attributes and their target fields are fixed.</li><li>The event ID (B.IDBASE) is inherited in addition to the attributes that are inherited when SS_MODE=1.</li></ul>                              | <ul style="list-style-type: none"><li>The event ID is required to be registered.</li><li>Linkage with JP1/IM - Manager, JP1/Service Support, and JP1/Navigation Platform is required.</li></ul>                                         | 10-10 or later                                                                |
| SS_MODE=3                  | <ul style="list-style-type: none"><li>The mapping between source attributes and target fields is configurable.</li><li>Multiple attributes can be mapped to one target field.</li><li>Any character string you want can be inherited.</li></ul> | <ul style="list-style-type: none"><li>Any attribute or character string you want is required to be registered.</li><li>This mode also allows linkage with JP1/IM - Manager, JP1/Service Support, and JP1/Navigation Platform.</li></ul> | 11-50 or later                                                                |

If you omit this parameter, or do not specify the value correctly, 1 is assumed. Note that if you specify this parameter more than once, the parameter on the last line is valid.

If you specify the registration mode of an incident, information to be registered as an incident is changed. For details about registration modes of incidents and information to be registered as incidents, see *10.1.1 Attributes of a JP1 event registered as an incident in JP1/Service Support during linkage* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

#comment-line

A line beginning with a hash mark (#) is treated as a comment.

[SS\_URL=http://JP1/Service Support-host:port-number]

Specifies the URL of a Web page for JP1/Service Support on which you can register an incident by using one-byte numeric values and symbols. The default is SS\_URL=, and no value is set.

The maximum length of a URL that calls JP1/Service Support is 2,046 characters. If 2 is set for the registration mode of an incident, event IDs are inherited. Therefore, the length of a message that can be inherited when 2 is set is less than the length of a message when 1 is set. If a message is truncated before the end, the user must copy the rest of the message displayed in the Event Details window, and paste it into JP1/Service Support.

When you code the port numbers of JP1/Service Support in this parameter, you must set them to ensure passage through the firewall between the JP1/IM - View machine and the JP1/Service Support machine.

To link with JP1/Service Support after upgrading JP1/IM - Manager, add this line, and then do the following:

- Change *version-information* to 2 or 3.
- Add SS\_MODE on a new line to specify the registration mode when you want to register an event ID (SS\_MODE=2) or you want a desired attribute or character string of a JP1 event to be inherited as an incident (SS\_MODE=3).
- Change the line beginning with IDM\_URL as the comment statement (add #).

Restart JP1/IM - Manager or execute the jco\_spmc\_reload command to apply the definitions. If you already logged in to JP1/IM - View, restart JP1/IM - View.

## ◆ Configuration file for incident inheritance information (incident\_info.conf)

### Format

```
[@encode UTF-8]
#item-field-ID=value-to-be-set-for-the-item
JP1/Service-Support-item-element-ID=value-passed-to-item-element[end-of-line
-character]
```

### File

incident\_info.conf (Configuration file for incident inheritance information)

incident\_info.conf.model (Model file for the configuration file for incident inheritance information)

### Storage directory

In Windows:

Physical hosts:

*Console-path*\conf\console\incident\

Logical hosts:

*shared-folder*\jplcons\conf\console\incident\

In UNIX:

Physical hosts:

/etc/opt/jplcons/conf/console/incident/

Logical hosts:

*shared-directory/jplcons/conf/console/incident/*

## Description

Attributes or character strings of a JP1 event can be inherited as an incident in JP1/Service Support. This file defines which attributes or character strings of a JP event are mapped to which item elements of the New item window in JP1/Service Support.

## When the definitions are applied

The settings edited in the configuration file for incident inheritance information take effect when you log in to JP1/IM - Manager (Central Console) with JP1/IM - View after setting the incident registration mode to 3 and then executing the `jco_spmc_reload` command or restarting JP1/IM - Manager.

## Information that is specified

`[@encode UTF-8]`

Specifies the character encoding of the configuration file for incident inheritance information. The `@encode` statement must be on the first line. When the `@encode` statement does not exist, the character encoding of the manager is used. The acceptable character encoding is UTF-8. When the specified character encoding is UTF-8, the character encoding of the configuration file is set to UTF-8.

The error message KAVB1115-W is issued and the character encoding of the manager is used when any of the following conditions is true:

- The configuration file does not begin with `@encode`.
- `@encode` is not followed by a character encoding value.

The error message KAVB1119-W is issued and the character encoding of the manager is used when the following condition is true:

- The specified character encoding is not UTF-8.

The managers use the following character encodings:

In Windows:

One of the following character encodings is used depending on the system locale:

Japanese: MS932 (Note that available characters are limited to SJIS characters.)

English: C

Chinese: GB18030

Any encoding other than Japanese or Chinese: C

In UNIX:

The character encoding depends on the value of the `LANG` environment variable specified in the `/etc/opt/jplcons/conf/jplco_env.conf` file.

*#comment-line*

A line beginning with a hash mark (#) is treated as a comment.

*JP1/Service-Support-item-element-ID=value-passed-to-item-element* *[end-of-line-character]*

Specifies which attributes or character strings of a JP1 event that are inherited as incidents are mapped to which item elements of the New item window in JP1/Service Support.

### *JP1/Service-Support-item-element-specification-ID*

Specifies an item element specification ID in JP1/Service Support. If there are multiple occurrences of the same ID, the first occurrence takes precedence. For details about item element specification IDs, see the *JP1/Service Support Configuration and Administration Guide*.

### *value-passed-to-item-element [end-of-line-character]*

Specifies any character strings or variables. You can specify as many multiple variables as you need.

A character string can consist of any characters other than control characters. When you include a control character (0x00 to 0x0F, 0x14 to 0x1F, or 0x7F), the character is replaced with a space (0x20). To use a dollar sign (\$) as a literal character, place an escape character \ immediately before the dollar sign (\$). To break a line, specify \n on the point where you want to break the line. To use \n as literal characters, specify \\n.

The following table describes how to specify a variable.

**Table 2–44: How to specify a variable**

| Format                                                                       | Description                                                                                                                                                                                                                                              |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>\$variable-name</i>                                                       | A variable must be specified in the following format: <i>\$variable-name</i> . For details about specific variable names of JP1 event attributes, see <a href="#">Table 2-46 Variables that can be specified for JP1/Service Support item elements</a> . |
| <i>\${variable-name}</i>                                                     | A variable name must be enclosed in curly brackets ( { } ) when the variable name is directly followed by an alphanumeric character or an underscore ( _ ).                                                                                              |
| <i>\$variable-name\$URLENC</i><br><i>\${variable-name\$URLENC}</i>           | The attribute value is URL-encoded with UTF-8 character encoding.                                                                                                                                                                                        |
| <i>\$variable-name\$ENC</i><br><i>\${variable-name\$ENC}</i>                 | The attribute value is Base64-encoded.                                                                                                                                                                                                                   |
| <i>\$variable-name\$ENC\$URLENC</i><br><i>\${variable-name\$ENC\$URLENC}</i> | The attribute value is Base64-encoded and then URL-encoded.                                                                                                                                                                                              |

The following table lists the examples of specified variables. These examples assume that the value of the event ID (\$EVID) is 100:0 and the value of the EX extended attribute (\$EV"EX") is ABC.

**Table 2–45: Examples of specified variables**

| Specified variable | Converted value                                                     |
|--------------------|---------------------------------------------------------------------|
| \$EVID abc         | 100:0 abc                                                           |
| \$EVIDabc          | In Windows<br>\$EVIDabc<br>In UNIX<br>Converted to an empty string. |
| \${EVID}abc        | 100:0abc                                                            |
| \$EVID_abc         | In Window<br>\$EVID_abc<br>In UNIX<br>Converted to an empty string. |
| \${EVID}_abc       | 100:0_abc                                                           |
| \$EV"EX" abc       | ABC abc                                                             |
| \$EV"EX"abc        | ABCabc                                                              |

The table below lists variables that can be used to pass the attribute values. You can map any source attribute to any target element but you must ensure that the value of the source attribute matches the display format of the target element.

Table 2–46: Variables that can be specified for JP1/Service Support item elements

| Item                                             | Information to be inherited                                                                                                                                                                                                                                                                                                                                                                                                                            | Variable name |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Entire basic event information                   | Entire basic event information                                                                                                                                                                                                                                                                                                                                                                                                                         | EVBASE        |
| Event ID ( <i>basic-code:extended-code</i> )     | Value of the event ID in the format <i>basic-code:extended-code</i> .<br><i>basic-code</i> is the value of the event ID (B.ID). <i>extended-code</i> is the value of the event code (extended code) (B.IDEXT). Both <i>basic-code</i> and <i>extended-code</i> are an 8-digit hexadecimal number (where A-F are uppercase). Zeros preceding the ID are omitted. When the extended code is 00000000, the value of the variable is <i>basic-code:0</i> . | EVID          |
| Event ID ( <i>basic-code</i> )                   | 8-digit hexadecimal number representing the event ID (basic code) (where A-F are uppercase). Zeros preceding the ID are omitted.                                                                                                                                                                                                                                                                                                                       | EVIDBASE      |
| Event registration date                          | Character value of the registration time (B.TIME) in the following format: <i>yyyy/mm/dd</i>                                                                                                                                                                                                                                                                                                                                                           | EVDATE        |
| Event registration time ( <i>hh:mm:ss</i> )      | Character value of the registration time (B.TIME) in the following format: <i>hh:mm:ss</i>                                                                                                                                                                                                                                                                                                                                                             | EVTIME        |

| Common exclude conditions group ID                   | Value of E.JP1_IMCOMEXCLUDE_ID<br>Only when the extended mode of common exclusion is enabled and the integrated monitoring database is enabled                                                                                                 | EV"JP1_IMCOMEXCLUDE_ID"      |
| Common exclude conditions group name                 | Value of E.JP1_IMCOMEXCLUDE_NAME<br>Only when the extended mode of common exclusion is enabled and the integrated monitoring database is enabled                                                                                               | EV"JP1_IMCOMEXCLUDE_NAME"    |
| Common exclude conditions group target-for-exclusion | Value of E.JP1_IMCOMEXCLUDE_TARGET<br>Only when the extended mode of common exclusion is enabled and the integrated monitoring database is enabled                                                                                             | EV"JP1_IMCOMEXCLUDE_TARGET"  |

When a variable name other than those listed above is specified, the statement including the variable is not replaced with event information. For example, when you use the variable AAA to compose the statement \$AAA, the literal characters \$AAA are passed to the New item window in JP1/Service Support.

When the value of an attribute that is specified in EV"*extended-attribute-name*" is not available, the statement including the variable is not replaced with event information. For example, when you specify the statement \$EV"BBB" but the JP1 event does not have the extended attribute BBB, the literal characters \$EV"BBB" are passed to the New item window in JP1/Service Support.

When the value of an attribute that is specified in a statement other than EV"*extended-attribute-name*" is not available, the statement including the variable is replaced with an empty string. For example, when you specify the statement \$EVSEV but the JP1 event does not have the extended attribute SEVERITY, "" (an empty string) is passed to the New item window in JP1/Service Support.

## Example definition

To show "Event that occurred on *event-source-host name (IP-address)* : *event-ID*" in the **Title** element of the New item window in JP1/Service Support (only when the event source host mapping is enabled):

```
TITLE=Event that occurred on $EV"JP1_SOURCEHOST" ($EVIPADDR) : $EVIDBASE
```

To show a URL link (by URL-encoding the attribute value with UTF-8 character encoding) in the **Related information** element of the New item window in JP1/Service Support:

```
LINKURL=http://host/page?msg=$EVMSG$URLENC
```

## ◆ Severity changing definition file (jcochsev.conf)

### Format

```
DESC_VERSION=version-information

def definition-name-1
  [cmt comment]
  [define {enable | disable}]
  [addflag {true | false}]
  cnd
    event-condition
  end-cnd
  sev event-level
end-def

def definition-name-2
  [cmt comment]
  [define {enable | disable}]
  [addflag {true | false}]
  cnd
    event-condition
  end-cnd
  sev event-level
end-def
```

### File

jcochsev.conf (severity changing definition file)

jcochsev.conf.model (model file for the severity changing definition file)

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\chsev\

For a logical host:

*shared-folder*\jplcons\conf\chsev\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/chsev/

For a logical host:

*shared-directory*/jplcons/conf/chsev/

## Description

This file defines conditions for changing the event level of JP1 events and the new event level. The event severity changing function changes the event level of a JP1 event if it satisfies an event condition defined in this file. Specify this file using the language encoding that is used by JP1/IM - Manager.

The maximum size of this file is 17 megabytes (17,825,792 bytes). There is no upper limit on the number of definitions.

There are two types of parameters in the severity changing definition file:

- Severity changing definition file version  
Defines the format version of the severity changing definition file.
- Severity changing definition parameter  
Defines a condition for JP1 events whose event level is to be changed and the new event level. The higher a severity changing definition is listed in the severity changing definition file, the higher its priority.

## When the definitions are applied

The definition takes effect when the event severity changing function is enabled, and one of the following operations is performed:

- JP1/IM - Manager is started.
- The `jco_spmc_reload` command is executed.
- The **OK** button is clicked in the Add Severity Change Definition Settings window.
- The **Apply** button is clicked in the View Severity Change Definitions window.

## Information that is specified (severity changing definition file version)

DESC\_VERSION

Specifies the file version that determines the format of this severity changing definition file as version information. Specify 2. If DESC\_VERSION is omitted, 2 is assumed as the file version.

Specify DESC\_VERSION on the first line of the definition file (the first line in the file excluding any null lines and comment lines). If there is no file version in the first line, 2 is assumed.

Table 2–47: Version information of the severity changing definition file format

| Version information | Description                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------|
| 1                   | Indicates version 10-10 or earlier as the version of the severity changing definition file. |
| 2                   | Indicates version 10-50 as the version of the severity changing definition file.            |

Table 2–48: List of parameters that can be specified in the severity changing definition file according to the version information

| Version information | Parameter name                                                                                                                                                  |

| 2                   | def to end-def (definition block)<br>cmt <i>comment</i><br>define {enable   disable}<br>addflag {true   false}<br>cnd to end-cnd (event condition block)<br>sev |

## Information that is specified (severity changing definition parameter)

As shown in the following figure, the definition parameter for changing severity consists of a definition block and an event condition block.

Figure 2–9: Parameter for changing severity

### def to end-def (definition block)

These are the start and end parameters for a severity changing definition. The block from `def` to `end-def` can be omitted, in which case the system assumes that the event level is not to be changed for any JP1 events. After `def`, specify the names of severity changing definitions. If you specify `def Δ Δ Δ definition-1 Δ Δ Δ definition-2 Δ Δ Δ`, then `Δ Δ definition-1 Δ Δ Δ definition-2 Δ Δ Δ` are treated as the definition names (Δ indicates a single-byte space).

For a definition name, specify a character string of from 1 to 50 bytes. Each definition name must be unique within the severity changing definition file. The permitted characters are all characters other than the control characters (from 0x00 to 0x1F and 0x7F to 0x9F).

### cmt *comment*

Describes the comment for the severity changing definition. The comment specified for `cmt` is displayed in the comment section of the Severity Change Definition Settings window. Only one `cmt` parameter can be specified in the definition block. This parameter can be omitted. Specify the comment within 1,024 bytes. The permitted characters are all characters other than the control characters (0x00 to 0x1F, and 0x7F to 0x9F).

If you specify this parameter when *version-information* is 1, an error occurs.

define {enable | disable}

Specifies whether to enable the severity changing definition. Only one `define` parameter can be specified in the definition block. To enable the severity changing definition, specify `enable`, to disable it, specify `disable`. The `define` parameter can be omitted. By default, `enable` is set. The values are not case sensitive.

If you specify this parameter when *version-information* is 1, an error occurs.

addflag {true | false}

Indicates an additional severity changing definition has been added from a window, and specifies whether the severity changing definition is an additional severity changing definition. Therefore, to edit the severity changing definition file, you do not need to specify the `addflag` parameter. Only one `addflag` parameter can be specified in the definition block. Specify `true` for the additional severity changing definition, and `false` for the severity changing definition. When `true` is specified, the icon (  ) is displayed in **Type** of the View Severity Change Definitions window. The `addflag` parameter can be omitted. By default, `false` is specified. The value is not case sensitive.

If you specify this parameter when *version-information* is 1, an error occurs.

cnd to end-cnd (event condition block)

These are the start and end parameters for the block that specifies a condition for the JP1 events whose event level is to be changed. You must specify one event condition block in a definition block. The event condition block cannot be omitted. If a received JP1 event satisfies multiple event conditions, the definition block closest to the beginning of the severity changing definition file is effective. Tabs and spaces before and after the `cnd` and `end-cnd` parameters are ignored.

*event-condition*

Specifies a condition for the JP1 events whose event level is to be changed. You can specify from 0 to 256 event conditions in an event condition block. You can specify from 1 to 256 event conditions per event condition block. When multiple event conditions are specified, it is assumed that they are connected with the AND condition. Specify the event conditions in the following format ( $\Delta$  indicates a single-byte space):

*attribute-name* $\Delta$ *comparison-keyword* $\Delta$ *operand* [ $\Delta$ *operand*] . . .

Note that a line consisting of only spaces or tabs is ignored during processing.

*attribute-name*

Specifies the name of the attribute that you want to compare. To specify a basic attribute, place `B .` immediately before the name. To specify an extended attribute (common information or user-specific information), place `E .` immediately before the name. The attribute names are case sensitive.

The following table lists and describes the combinations of attribute names and comparison keywords and the operands that can be specified.

Table 2–49: Combinations of attribute names and comparison keywords and the operands that can be specified

| No. | Item                    | Attribute name | Comparison keyword                                                           | Operand                                                                                                                                                                    |
|-----|-------------------------|----------------|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Event ID                | B.ID           | <ul style="list-style-type: none"><li>Match</li><li>Does not match</li></ul> | A maximum of 100 event IDs can be specified.<br>Specify event IDs in hexadecimal notation. Event IDs are not case sensitive.<br>The permitted range is from 0 to 7FFFFFFF. |
| 2   | Reason for registration | B.REASON       | <ul style="list-style-type: none"><li>Match</li><li>Does not match</li></ul> | A maximum of 100 reasons for registration can be specified.                                                                                                                |
| 3   | Source process ID       | B.PROCESSID    | <ul style="list-style-type: none"><li>Match</li><li>Does not match</li></ul> | A maximum of 100 source process IDs can be specified.                                                                                                                      |

| No. | Item                                                  | Attribute name | Comparison keyword                                                                                                                                                                                | Operand                                                                                                                                                |
|-----|-------------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |                                                       |                |                                                                                                                                                                                                   | The permitted value range is from -2,147,483,648 to 2,147,483,647.                                                                                     |
| 4   | Source user ID                                        | B.USERID       | <ul style="list-style-type: none"> <li>• Match</li> <li>• Does not match</li> </ul>                                                                                                               | <p>A maximum of 100 source user IDs can be specified.</p> <p>The permitted value range is from -2,147,483,648 to 2,147,483,647.</p>                    |
| 5   | Source group ID                                       | B.GROUPID      | <ul style="list-style-type: none"> <li>• Match</li> <li>• Does not match</li> </ul>                                                                                                               | <p>A maximum of 100 source group IDs can be specified.</p> <p>The permitted value range is from -2,147,483,648 to 2,147,483,647.</p>                   |
| 6   | Source user name                                      | B.USERNAME     | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Does not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 source user names can be specified. However, if a regular expression is used, only one source user name is allowed.                   |
| 7   | Source group name                                     | B.GROUPNAME    | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Does not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 source group names can be specified. However, if a regular expression is used, only one source group name is allowed.                 |
| 8   | Event-issuing server name (source host) <sup>#1</sup> | B.SOURCESERVER | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Does not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 event-issuing server names can be specified. However, if a regular expression is used, only one event-issuing server name is allowed. |
| 9   | Target event server name <sup>#1</sup>                | B.DESTSERVER   | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Does not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 target event server names can be specified. However, if a regular expression is used, only one target event server name is allowed.   |
| 10  | Message                                               | B.MESSAGE      | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Does not match</li> </ul>                                                                                   | A maximum of 100 messages can be specified. However, if a regular expression is used, only one message is allowed.                                     |

However, if a regular expression is used, only one termination code is allowed.             |
| 21  | Event source host name <sup>#1</sup> | E.JP1_SOURCEHOST   | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Do not match</li> <li>• Is contained</li> <li>• Is not contained</li> </ul>                                 | A maximum of 100 event source host names can be specified. However, if a regular expression is used, only one event source host name is allowed. |

| No. | Item                                              | Attribute name | Comparison keyword                                                                                                                                                                    | Operand                                                                                                                                                                                                                                                                                                                                                     |
|-----|---------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |                                                   |                | <ul style="list-style-type: none"> <li>Regular expression</li> </ul>                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                             |
| 22  | Program-specific extended attribute <sup>#2</sup> | E .xxxxxx      | <ul style="list-style-type: none"> <li>First characters</li> <li>Match</li> <li>Does not match</li> <li>Is contained</li> <li>Is not contained</li> <li>Regular expression</li> </ul> | <p>For the attribute name, you can specify a name with a maximum length of 32 bytes that begins with an uppercase letter and consists of uppercase letters, numeric characters, and the underscore (_).</p> <p>A maximum of 100 extended attributes can be specified. However, if a regular expression is used, only one extended attribute is allowed.</p> |

#1

If the integrated monitoring database and the IM Configuration Management database are enabled, and the comparison keyword is *Match* or *Do not match*, the business group name can be specified in a path format.

If the integrated monitoring database and the IM Configuration Management database are disabled, and a comparison keyword other than *Match* and *Do not match* is selected, a business group name specified in a path format is treated as a host name.

If the *-ignorecasehost* option of the *jcoimdef* command is set to *ON*, and a comparison keyword other than *Regular expression* is selected, the character string is no longer case sensitive.

#2

You can also specify a JP1 product-specific extended attribute. For example, the program-specific extended attribute for the JP1/AJS job execution host is *E .C0*. For details about the product-specific extended attributes, consult the documentation for the products that issue JP1 events.

#### •*comparison-keyword*

Specifies one of *BEGIN* (begins with), *IN* (matches), *NOTIN* (does not match), *SUBSTR* (includes), *NOTSUBSTR* (does not include), or *REGEX* (regular expression) as the comparison keyword. The comparison keyword is case sensitive.

#### •*operand*

Specifies a character string as the value that is to be compared with the attribute value by the specified comparison keyword. Operands are case sensitive.

Separate multiple operands with one or more consecutive spaces or a tab. The *OR* condition is applied to the specified operands. Note that if a regular expression is specified, only one operand can be specified.

To specify a space, a tab, end-of-line code (CR or LF), or % as part of an operand, specify as follows:

| No. | Value to be set                | How to specify |
|-----|--------------------------------|----------------|
| 1   | Tab (0x09)                     | %09            |
| 2   | Space (0x20)                   | %20            |
| 3   | % (0x25)                       | %25            |
| 4   | Linefeed code LF (0x0a)        | %0a            |
| 5   | Carriage return code CR (0x0d) | %0d            |

During maximum value checking for the definition format, %20 and %25 are each treated as a single character. The character code specified after the % is not case sensitive. The following shows an example of defining ID matches 100 and 200, which selects multiple operands:

B.IDΔINΔ100Δ200

Legend:

Δ: Space (0x20)

You can specify a maximum of 4,096 bytes of operands per event condition and per event condition block (total length in bytes of all operands that are specified in the event condition block).

`sev`

Specifies the new event level after the change.

You must specify one `sev` parameter in a definition block. This parameter cannot be omitted.

You can specify in the `sev` parameter Emergency, Alert, Critical, Error, Warning, Notice, Information, or Debug.

*#comment-line*

A line beginning with a hash mark (#) is treated as a comment. Note that if you set the severity changing definition from JP1/IM - View, the comment line beginning with # is deleted.

## Example definition

Change the event level to Emergency when the event ID is 100 or 200, the existing event level is Warning, and the source host is hostA, hostB, or hostC:

```
DESC_VERSION=2
def Event level change 1
  cmt comment1
  define enable
  cnd
    B.ID IN 100 200
    E.SEVERITY IN Warning
    B.SOURCESERVER IN hostA hostB hostC
  end-cnd
  sev Emergency
end-def
```

## ◆ Command button definition file (cmdbtn.conf)

### Format

```
DESC_VERSION=file-version

#comment-line
def
  [usr target-user-name target-user-name ...]

  btn command-button-name
    [cmt comment-about-command-button]
    [cmdtype {agent|client}]
    [inev {true|false}]
    [hst target-host]
    cmd command-line
    [var environment-variable-file-name]
    [qui {true|false}]
    [preview {true|false}]
  end-btn
  :
  :
end-def
```

```
:
```

## File

cmdbtn.conf

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\rmtrcmd\

For a logical host:

*shared-folder*\jplcons\conf\console\rmtrcmd\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/console/rmtrcmd/

For a logical host:

*shared-directory*/jplcons/conf/console/rmtrcmd/

## Execution permission

In Windows

Administrators group and SYSTEM users

In UNIX

Users with the root permissions

## Description

This file defines the command buttons to be displayed in the Execute Command window. The maximum size of the command button definition file is 10 megabytes. If there are multiple command button definitions that can be used, the definition listed first in the command button definition file is displayed.

## When the definitions are applied

If the `jcoimdef` command has been executed to enable the command button, the command button definitions are applied when the Execute Command window opens.

Note that if you change the definition of the command button while JP1/IM - View is running, you must restart JP1/IM - View.

## Information that is specified

DESC\_VERSION=*file-version*

Specifies the version of the format of the command button definition file. The specifiable values are 1 and 2. To use the functionality that inherits the client application or event information, specify 2. When 2 is specified, the following parameters can be specified:

- cmdtype
- inev

- preview

When the file version is omitted or a numeric value other than 1 or 2 is specified, 1 is assumed.

#### *#comment-line*

A line beginning with a hash mark (#) is treated as a comment.

#### *def to end-def (definition block)*

These are the start and end parameters of the command button definition. You can specify a maximum of 64 parameters.

[usr *target-user-name target-user-name ...*]

Specifies the names of JP1 users who use the command button. The number of characters you can specify for each target user name is from 1 to 31 bytes. Only one-byte alphanumeric characters can be used. Alphabets are not case sensitive. To specify multiple names, separate the names by one or more consecutive spaces or tabs. You can specify a maximum of 100 target user names. Target user names from the 101st are ignored. If this parameter is omitted, all JP1 users become target users. One target user name can be specified between *def* and *end-def*. No target user names can be specified between *btn* and *end-btn*.

*btn command-button-name to end-btn*

Specify the start and the end of a command button. *command-button-name* is displayed as the name of a command button in the Execute Command window. You can specify a maximum of eight characters for *command-button-name*. Specifiable characters are characters other than control characters (0x00 to 0x1F, 0x7F to 0x9F). The command button name is case sensitive. A maximum of 16 command buttons can be specified in a definition block. The same command button name cannot be specified twice. If *command-button-name* exceeds the limit for number of characters or the same command button name is specified twice, the command button name cannot be loaded.

[cmt *comment-about-command-button*]

Provides a description of the command button. The comment is displayed as a tool tip. This parameter can be omitted. You can specify a maximum of 40 characters for the comment. Characters from the 41st are ignored. You can specify any characters.

[cmdtype {agent|client}]

Specifies the type of command executed by a command button. Select whether the button will be used for managed-host commands or by client applications. Client applications are executed by the client application execution functionality. If you specify this parameter, specify 2 for DESC\_VERSION.

For command execution on an agent or a manager host, specify the *agent* parameter. For command execution by a client application, specify the *client* parameter.

If you specify *client* for *cmdtype*, you cannot specify the *hst* and *var* parameters.

*agent* and *client* are not case sensitive.

[inev {true|false}]

Specifies whether to inherit event information by using the command button. If you specify this parameter, specify 2 for DESC\_VERSION.

Specify *true* to execute the command by inheriting event information specified when you click the command button, or specify *false* not to execute the command. If this parameter is omitted, *false* is assumed.

*true* and *false* are not case sensitive.

[hst *target-host*]

Specifies the name of the host on which the command is executed. For *target-host*, you can specify a host name, host group name, business group name, or monitoring group name.

For a host name or a host group name, you can specify a character string with a maximum of 255 bytes. For a business group name or a monitoring group name, you can specify a character string with a maximum of 2,048 bytes. This parameter can be omitted.

If the integrated monitoring database and the IM Configuration Management database are enabled, the business group name can be specified in a path format.

If the integrated monitoring database and the IM Configuration Management database are disabled, and you specify the business group name in a path format, the name is treated as a host name or a host group name.

Specify a variable to hold the inherited event information. For details about the inherited event information that can be specified, see *4.19.5(1) Specifiable event inheritance information* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*. To specify inheritance of event information, specify `true` for the `inev` parameter. If you make this specification, make sure that the length of the character string following replacement of the variable with JP1 event information is equal to or less than the maximum number of bytes permitted for *target-host*. If the length of the character string exceeds the limit, a truncated character string is specified as the target host name in the environment variable file.

`cmd` *command-line*

Specifies the command to be executed. You can specify a maximum of 4,096 bytes for the command line. This parameter cannot be omitted.

Specify a variable to hold the inherited event information. To specify inheritance of event information, specify `true` for the `inev` parameter. If you make this specification, make sure that the length of the character string following replacement of the variable with JP1 event information is equal to or less than the maximum number of bytes permitted for *target-host*. If the length of the character string exceeds the limit, a truncated character string is specified as the target host name in the environment variable file.

[`var` *environment-variable-file-name*]

Specifies the name of the environment variable file in which the environment variable of the command to be executed is specified. This parameter can be omitted. For details about the environment variable file format, see the *JP1/Base User's Guide*. You can specify a character string with a maximum of 255 bytes for the environment variable file name. If the environment variable file name exceeds the limit, the command button is not loaded.

Specify a variable for the inherited event information. To specify inherited event information, specify `true` for the `inev` parameter. When you specify inherited event information, make sure that the length of a character string following replacement of the variable with JP1 event information is equal to or less than the maximum number of bytes permitted for the environment variable file. If the length of the character string exceeds the limit, a truncated character string is specified as the target host name in the environment variable file.

[`qui` {`true`|`false`}]

Specifies whether to display a message confirming that the command can be executed before executing a command with a command button. If the confirmation message is not displayed, the command is executed at the same time the command button is clicked.

Specify `true` if you want the confirmation message to be displayed. Specify `false` if you do want the message to be displayed. If this parameter is omitted, `false` is assumed. However, if `true` is specified for the `preview` parameter, the Preview Command Execution Content window opens.

`true` and `false` are not case sensitive.

[`preview` {`true`|`false`}]

If you inherit event information by using a command button, this parameter specifies whether to check the action definition of the command with the preview function after event information is inherited. To specify this parameter, specify 2 for `DESC_VERSION`.

Specify `true` to display the preview window. Specify `false` if you do not want to display the preview window. If this parameter is omitted, `true` is assumed.

`true` and `false` are not case sensitive.

This parameter is ignored if `false` is specified for the `inev` parameter.

If false is specified for the preview parameter and true is specified for the qui parameter, the command is executed at the same time the command button is clicked. The Preview Command Execution Content window and a message to confirm command execution are not displayed.

## Example definition

```
DESC_VERSION=2

def
# Execute the command on the viewer host.
# Specify inherited event information for the command to be executed.
# Before executing the command, display the preview window.
  btn App1
    cmt Execute App1.
    cmdtype client
    inev true
    cmd C:\kansi\app1.exe $EVIDBASE $EVSEQNO "$EVMSG"
  end-btn

# Execute the command on the viewer host.
# Specify inherited event information for the command to be executed.
# Before executing the command, display the confirmation dialog box. The pre
view window is not displayed.
  btn App2
    cmt Execute App2.
    cmdtype client
    inev true
    cmd C:\kansi\app2.exe $EVIDBASE $EVSEQNO "$EVMSG"
    preview false
  end-btn

# Execute the command on the viewer host.
# Specify inherited event information for the command to be executed.
# Do not display the dialog box and the preview window before executing the
command.
  btn App3
    cmt Execute App3.
    cmdtype client
    inev true
    cmd C:\kansi\app3.exe $EVIDBASE $EVSEQNO "$EVMSG"
    qui true
    preview false
  end-btn

# Execute the command on the agent or the manager host.
# Specify inherited event information for the command to be executed.
# Display the preview window before executing the command.
  btn Cmd1
    cmt Execute cmd1.
    cmdtype agent
    inev true
    hst $EVHOST
    cmd /kansi/cmd1 $EVIDBASE $EVSEQNO '$EVMSG'
  end-btn

# Execute the command on the agent or the manager host.
# Do not specify inherited event information for the command to be executed.
```

```
# Display the confirmation dialog box before executing the command.
  btn Cmd2
    cmt Execute cmd2.
    hst agent2
    cmd /kansi/cmd2
  end-btn
end-def
```

## ◆ File that defines which items are displayed for event conditions (attr\_list.conf)

### Format

```
# comment-line
attribute-name
attribute-name
attribute-name
.
.
.
attribute-name
```

### File

attr\_list.conf (file that defines which items are displayed for event conditions)

attr\_list.conf.model (model file for the file that defines which items are displayed for event conditions)

### Storage directory

#### In Windows

For a physical host:

*Console-path*\conf\action\attr\_list

For a logical host:

*shared-folder*\jplcons\conf\action\attr\_list

#### In UNIX

For a physical host:

/etc/opt/jplcons/conf/action/attr\_list

For a logical host:

*shared-directory*/jplcons/conf/action/attr\_list

### Description

This file defines the items to be displayed in the **Attribute name** field in the Action Parameter Detailed Definitions window. The Action Parameter Detailed Definitions window displays the items in the **Attribute name** field in the order they are specified in this file.

## When the definitions are applied

The file that defines which items are displayed for event conditions is loaded when Central Console is started or when the `jco_spmc_reload` command is executed. When JP1/IM - View displays the Action Parameter Definitions window, it acquires the contents of the file that defines the items and which was loaded by Central Console, and then applies the file's contents to the Action Parameter Detailed Definitions window.

## Information that is specified

### *attribute-name*

Specifies an item to be displayed in the **Attribute name** field of the Action Parameter Detailed Definitions window. Specify the attribute name of each item that is to be displayed with one item per line. You can specify from 0 to 256 items.

An attribute name is case sensitive. Any space or tab character immediately preceding or following the attribute name will be ignored.

The table below lists the attribute names that can be specified.

If you specify `SEPARATOR`, a horizontal line, such as `-----`, is displayed in the **Attribute name** field of the Action Parameter Detailed Definitions window. You can use `SEPARATOR` to separate the items that are used often from the items that are used infrequently.

If you specify only `SEPARATOR`, only a horizontal line is displayed in the **Attribute name** field. In such a case, no event condition can be set by selecting the separator line and then adding an event condition.

Table 2–50: List of items that can be displayed

| No. | Display item                        | Attribute name           |
|-----|-------------------------------------|--------------------------|
| 1   | Source host                         | B.SOURCESERVER           |
| 2   | Event level                         | E.SEVERITY               |
| 3   | Object type                         | E.OBJECT_TYPE            |
| 4   | Object name                         | E.OBJECT_NAME            |
| 5   | Root object type                    | E.ROOT_OBJECT_TYPE       |
| 6   | Root object name                    | E.ROOT_OBJECT_NAME       |
| 7   | Occurrence                          | E.OCCURRENCE             |
| 8   | User name                           | E.USER_NAME              |
| 9   | Message                             | B.MESSAGE                |
| 10  | Product name                        | E.PRODUCT_NAME           |
| 11  | Event ID                            | B.ID                     |
| 12  | Start time                          | E.START_TIME             |
| 13  | End time                            | E.END_TIME               |
| 14  | Registered time                     | B.TIME                   |
| 15  | Arrived time                        | B.ARRIVEDTIME            |
| 16  | Program-specific extended attribute | OTHER_EXTENDED_ATTRIBUTE |
| 17  | Reason for registration             | B.REASON                 |
| 18  | Source process ID                   | B.PROCESSID              |
| 19  | Source user name                    | B.USERNAME               |

| No. | Display item               | Attribute name   |
|-----|----------------------------|------------------|
| 20  | Source user ID             | B.USERID         |
| 21  | Source group name          | B.GROUPNAME      |
| 22  | Source group ID            | B.GROUPID        |
| 23  | Source IP address          | B.SOURCEIPADDR   |
| 24  | Object ID                  | E.OBJECT_ID      |
| 25  | Result code                | E.RESULT_CODE    |
| 26  | Event source host name     | E.JP1_SOURCEHOST |
| 27  | Basic event information    | B.BASIC          |
| 28  | Detailed event information | B.DETAIL         |
| 29  | -----                      | SEPARATOR        |

Note:

If an attribute name has already been specified, subsequent specifications of the same name are ignored.

If the event display item definition file could not be read and the number of valid display items is zero, items 1 through 25 are displayed.

#### *#comment-line*

A line beginning with a hash mark (#) is treated as a comment.

## ◆ Configuration file for converting information (event\_info\_replace.conf)

### Format

```
character-before-conversion=character-string-after-conversion
character-before-conversion=character-string-after-conversion
:
character-before-conversion=character-string-after-conversion
```

### File

event\_info\_replace.conf

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\action

For a logical host:

*shared-folder*\jplcons\conf\action

In UNIX

For a physical host:

/etc/opt/jplcons/conf/action

For a logical host:

*shared-directory*/jplcons/conf/action

### File permissions

The following permissions are needed to use the configuration file for converting information:

In Windows

The Administrators group and SYSTEM users must be able to reference the file.

In UNIX

Users with the root permissions must be able to reference the file.

### Description

This file specifies the following conversion rules:

- Conversion rules for the event takeover information transform function of the auto action and command execution.
- Conversion rules of string for suggestion activation condition and response action when type is cmd in suggestion function.
- Conversion rules of string for auto response action and manual response action when type is cmd

The above string can convert certain ASCII characters in event-takeover information to another string according to conversion rules of configuration file for converting information.

For details about suggestion activation criteria with type cmd and response action strings in the suggestion function, see [Suggestion definition file \(imdd\\_suggestion.conf\)](#) in *Chapter 2. Definition Files*.

For details on when type `cmd` in auto response action, see the section *Automatic execution of response actions* of Chapter 7. *Automatic execution and manual execution of response action (JP1/IM - Agent linkage)* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

For details on when type `cmd` in manual response action, see the section *Manual execution of response actions* of Chapter 7. *Automatic execution and manual execution of response action (JP1/IM - Agent linkage)* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

The configuration file for converting information is not created when JP1/IM - Manager is installed. To use this configuration file, use a text editor to create and edit `event_info_replace.conf`.

## When the definitions are applied

For an automated action:

The contents of the configuration file for converting information take effect when JP1/IM - Manager starts, when the **Apply** button is clicked on the Action Parameter Definitions window of JP1/IM - View, and when the `jccachechange` command is executed to reload the definition.

For command execution:

The contents of the configuration file for converting information take effect when the Execute Command window opens.

For the Intelligent Integrated Management Base (suggestion function, auto and manual execution function in Response Action):

The contents of the configuration file for converting information take effect when the JP1/IM3-Manager service is started, when the `jddupdatesuggestion` command is executed to reload the suggestion definition, or when REST API is execute to load the auto response action definition.

If loading the configuration file for converting information fails when the JP1/IM3-Manager service is started, conversion is made with no conversion rule.

If loading the configuration file for converting information fails when the `jddupdatesuggestion` command is executed to load the suggestion definition, or when REST API is execute to load the auto response action definition, conversion is made with the conversion rules before the suggestion definition is loaded.

Note that if there is no configuration file for converting information, the function works without any conversion rule.

## Information that is specified

*character-before-conversion=character-string-after-conversion*

Define in the configuration file for converting information conversion rules for the event inheritance information conversion function. Each rule consists of a *character-before-conversion* and a *character-string-after-conversion*. You can specify from 0 to 34 conversion rules.

Lines consisting of only spaces, tabs, or linefeed codes in the event inheritance information conversion settings file are ignored. Specify one conversion rule per line. Separate the character before conversion from the character string after conversion with an equal sign (=).

A defined line that is not in the format *character-before-conversion=character-string-after-conversion* is ignored and processing continues. If no character string after conversion is specified, the function assumes that the specified character before conversion is to be deleted from the event inheritance information.

There can be only one conversion rule for the same character before conversion. If more than one conversion rule is specified for the same character before conversion, the first conversion rule specified takes effect and the subsequent conversion rules for that character are ignored.

If the event inheritance information contains a control character (0x01 to 0x08, 0x0A to 0x1F, or 0x7F), the control character is converted to a space (0x20).

If either of the following applies, the conversion rules are ignored and processing continues:

- A character that cannot be specified as a character before conversion is specified.
- Two or more characters are specified as a character before conversion.

#### *character-before-conversion*

As a character before conversion, you can specify an ASCII character (0x00 to 0x7F) indicated by *Y* in the applicable *character-before-conversion* column of the table below.

The table below lists the ASCII characters that can be specified as the character before conversion.

**Table 2–51: Characters that can be specified as a character before conversion and a character string after conversion**

| Character         | Hexadecimal value | <i>character-before-conversion</i> | <i>character-string-after-conversion</i> |
|-------------------|-------------------|------------------------------------|------------------------------------------|
| Control character | 0x00 to 0x08      | N                                  | N                                        |
| Tab               | 0x09              | Y                                  | Y                                        |
| Control character | 0x0a to 0x1f      | N                                  | N                                        |
| Space             | 0x20              | Y                                  | Y                                        |
| !                 | 0x21              | Y                                  | Y                                        |
| "                 | 0x22              | Y                                  | Y                                        |
| #                 | 0x23              | Y                                  | Y                                        |
| \$                | 0x24              | Y                                  | Y                                        |
| %                 | 0x25              | Y                                  | Y                                        |

|-----------|-------------------|------------------------------------|------------------------------------------|
| [         | 0x5b              | Y                                  | Y                                        |
| \         | 0x5c              | Y                                  | Y                                        |
| ]         | 0x5d              | N                                  | Y                                        |
| ^         | 0x5e              | Y                                  | Y                                        |
| _         | 0x60              | Y                                  | Y                                        |
| {         | 0x7b              | Y                                  | Y                                        |
|           | 0x7c              | Y                                  | Y                                        |
| }         | 0x7d              | Y                                  | Y                                        |
| ~         | 0x7e              | Y                                  | Y                                        |

Legend:

Y: Can be specified

N: Cannot be specified

#### *character-string-after-conversion*

As a character string after conversion, you can specify 0 to 2 ASCII characters (0x00 to 0x7F) indicated by *Y* in the applicable *character-string-after-conversion* column of the above table.

## Example definition

The following shows examples of converting ", ', and \* to \_:

```
"=_
'=_
*=_
_
```

When the value for a message (B.MESSAGE) receives a JP1 event, The Web server goes down. Details: "NetworkΔError", the value for the entire message text (variable: EVMSG) will be The Web server goes down. Details: \_NetworkΔError\_.

## ◆ Item file

### Format

```
[@] item-name
# comment-line
:
```

### File

Use any file.

## Storage directory

In Windows

Any folder

In UNIX

Any directory

## Description

This file specifies the JP1 event attributes that are to be output during output of event reports.

The maximum size of this file is 32 kilobytes (32,768 bytes).

### Definition specification

- A line consisting of only single-byte spaces or tabs is ignored.
- Single-byte spaces and tabs before the first parameter name on each line, and at the end of each line are ignored.

## When the definitions are applied

When the `jcoevtreport` command with the `-k` option specified is executed, the specified item file is loaded and the attribute values of JP1 events are output to event reports according to the item file.

## Contents of the file

### *item-name*

Specifies the items you want to output in an event report.

The following table lists and describes the items you can specify.

| No. | Specifiable item | Description                           |
|-----|------------------|---------------------------------------|
| 1   | B.SEQNO          | Serial number                         |
| 2   | B.ID             | Event ID                              |
| 3   | B.PROCESSID      | Source process ID                     |
| 4   | B.TIME           | Registered time                       |
| 5   | B.ARRIVEDTIME    | Arrived time                          |
| 6   | B.REASON         | Reason for registration               |
| 7   | B.USERID         | Source user ID                        |
| 8   | B.GROUPID        | Source group ID                       |
| 9   | B.USERNAME       | Source user name                      |
| 10  | B.GROUPNAME      | Source group name                     |
| 11  | B.SOURCESERVER   | Source host                           |
| 12  | B.DESTSERVER     | Target event server name              |
| 13  | B.SOURCEIPADDR   | Source IP address                     |
| 14  | B.DESTIPADDR     | Target IP address                     |
| 15  | B.SOURCESEQNO    | Source event database sequence number |
| 16  | B.CODESET        | Code set                              |

| No. | Specifiable item                   | Description                       |
|-----|------------------------------------|-----------------------------------|
| 17  | B.MESSAGE                          | Message                           |
| 18  | E.SEVERITY                         | Event level                       |
| 19  | E.USER_NAME                        | User name                         |
| 20  | E.PRODUCT_NAME                     | Product name                      |
| 21  | E.OBJECT_TYPE                      | Object type                       |
| 22  | E.OBJECT_NAME                      | Object name                       |
| 23  | E.ROOT_OBJECT_TYPE                 | Root object type                  |
| 24  | E.ROOT_OBJECT_NAME                 | Root object name                  |
| 25  | E.OBJECT_ID                        | Object ID                         |
| 26  | E.OCCURRENCE                       | Occurrence                        |
| 27  | E.START_TIME                       | Start time                        |
| 28  | E.END_TIME                         | End time                          |
| 29  | E.RESULT_CODE                      | Return code                       |
| 30  | E.JP1_SOURCEHOST                   | Event source host name            |
| 31  | E.@JP1IM_ACTTYPE                   | Action type                       |
| 32  | E.@JP1IM_ACTCONTROL                | Action                            |
| 33  | E.@JP1IM_SEVERE                    | Severe event                      |
| 34  | E.@JP1IM_CORRELATE                 | Correlation event                 |
| 35  | E.@JP1IM_RESPONSE                  | Response waiting event            |
| 36  | E.@JP1IM_ORIGINAL_SEVERITY         | Original severity level           |
| 37  | E.@JP1IM_CHANGE_SEVERITY           | New severity level                |
| 38  | E.@JP1IM_DEALT                     | Event status                      |
| 39  | E.@JP1IM_RELEASE                   | Canceling severe events           |
| 40  | E.@JP1IM_DISMISSED                 | Severe event deleted              |
| 41  | E.@JP1IM_MEMO                      | Memo                              |
| 42  | E.@JP1IM_DISPLAY_MESSAGE           | Changed display message           |
| 43  | E.@JP1IM_CHANGE_MESSAGE            | New display message               |
| 44  | E.@JP1IM_CHANGE_MESSAGE_NAME       | Display message change definition |
| 45  | E.user-specific extended attribute | Extended attribute                |

If there is no corresponding attribute in a JP1 event, the null character is output.

In addition, if you specify @ at the beginning of an item name, the date and time item for the basic or extended attribute is output, in the format *YYYYMMDDhhmmss*.

However, if any of the attributes of a JP1 event contain any of the following values, the value of the date and time item is output as is, even if @ is specified.

- nonnumeric value
- value less than 0, or value greater than 4,102,444,800

### #comment-line

A line beginning with a hash mark (#) is treated as a comment.

## ◆ Environment definition file for event report output (evtreport.conf)

### Format

```
[logical-host-name\JP1CONSOLEMANAGER]
"PROGRAM_SPECIFIC_EX_ATTR_COLUMN"=dword:hexadecimal-value
```

### File

evtreport.conf.update (model file for the environment definition file for event report output)

### Storage directory

In Windows

*Console-path*\default\

In UNIX

/etc/opt/jplcons/default/

### Description

This file defines the execution environment of the event report output function. It specifies whether to enable the function.

The required definitions are provided as a model file. To change the settings, copy the model file and edit the copy after renaming the copy to definition file (for Windows: *console-path*\conf\evtreport.conf, for UNIX: /etc/opt/jplcons/conf/evtreport.conf).

### When the definitions are applied

The definitions take effect when JP1/IM - Manager is restarted after the jbssetcnf command has been executed in JP1/Base to apply the definitions to the JP1 common definition information.

### Information that is specified

[logical-host-name\JP1CONSOLEMANAGER]

Indicates the key name of the JP1/IM - Manager environment settings.

For *logical-host-name*, specify JP1\_DEFAULT for a physical host and *logical-host-name* for a logical host.

"PROGRAM\_SPECIFIC\_EX\_ATTR\_COLUMN"=dword:*hexadecimal-value*

Specifies whether to enable the function for assigning a column to each program-specific extended attribute function when program-specific extended attributes are output using the `jcoevtreport` command, in the same way as for basic attributes, common extended attributes, and IM attributes.

- 00000001: Enable
- 00000000: Disable

The default value is 00000001 (enable).

## Example definition

```
[JP1_DEFAULT\JP1CONSOLEMANAGER]
"PROGRAM_SPECIFIC_EX_ATTR_COLUMN"=dword:00000001
```

## ◆ Filter file

### Format

```
event-condition
:
OR
event-condition
:
EXCLUDE
event-condition
:
```

### File

Use any file.

### Storage directory

In Windows

Any folder

In UNIX

Any directory

### Description

This file defines filter conditions to be applied during output of event reports. To load the file, execute the `jcoevtreport` command with the `-f` option specified.

The maximum size of this file is 256 kilobytes (262,144 bytes).

### When the definitions are applied

When the `jcoevtreport` command with the `-f` option specified is executed, the specified item file is loaded and the JP1 events that satisfy the specified condition are acquired from the integrated monitoring database and then output to an event report.

## Contents of the file

### *pass-conditions group, exclusion-conditions group*

The `jcoevtreport` command outputs the JP1 events that do not satisfy any of the exclusion-conditions groups and that satisfy one of the pass-conditions groups. For the filter conditions, you can specify from 0 to 5 pass-conditions groups and from 0 to 5 exclusion-conditions groups.

In a pass-conditions group or exclusion-conditions group, you can specify from 0 to 50 event conditions. In the case of an extended attribute (user-specific information), you can specify a maximum of 5 event conditions per pass-conditions group or exclusion-conditions group.

OR

If you specify multiple condition groups, specify OR between the condition groups.

EXCLUDE

Specify EXCLUDE between a pass-conditions group and an exclusion-conditions group. Any event condition that follows EXCLUDE is treated as an exclusion-conditions group. If no event condition follows EXCLUDE, only the pass-conditions groups take effect.

### *event-condition*

Specify the event conditions in the following format ( $\Delta$  indicates a single-byte space):

*attribute-name* $\Delta$ *comparison-keyword* $\Delta$  *operand* [ $\Delta$ *operand*] . . .

Note that a line consisting of only spaces or tabs is ignored during processing.

#### *attribute-name*

Specifies the name of the attribute that you want to compare. To specify a basic attribute, place `B .` immediately before the name; to specify an extended attribute (common information or user-specific information), place `E .` immediately before the name. Attribute names are case sensitive.

#### *comparison-keyword*

Specifies one of BEGIN (begins with), IN (matches), NOTIN (does not match), SUBSTR (includes), NOTSUBSTR (does not include), or REGEX (regular expression) as the comparison keyword. The comparison keyword is case sensitive.

#### *operand*

Specifies a character string as the value that is to be compared with the attribute value by the specified comparison keyword. Operands are case sensitive.

Specify multiple operands by separating them with one or more consecutive spaces or a tab. The OR condition is applied to the specified operands. Note that if a regular expression is specified for the comparison keyword, only one operand can be specified.

To specify a space, a tab, end-of-line code (CR or LF), or % as a part of an operand, specify as follows:

| No. | Value to be specified          | How to specify |
|-----|--------------------------------|----------------|
| 1   | Tab (0x09)                     | %09            |
| 2   | Space (0x20)                   | %20            |
| 3   | % (0x25)                       | %25            |
| 4   | Linefeed code LF (0x0a)        | %0a            |
| 5   | Carriage return code CR (0x0d) | %0d            |

During maximum value checking for the definition format, %20 and %25 are each treated as a single character. The character code specified after the % is not case sensitive. The following shows an example of defining ID matches 100 and 200, which selects multiple operands:

B.ID△IN△100△200

Legend:

△: Space (0x20)

You can specify a maximum of 4,096 bytes of operands per event condition and per event condition block (total length of operands in bytes that are specified in the event condition block). The following table shows the attribute names, comparison keywords, and operands that can be specified for event conditions.

| No. | Item                                    | Attribute name | Comparison keyword                                                                                                                                                                    | Operand                                                                                                                                                                                                                                                                                                                                                                                                                     |

#1

If the integrated monitoring database and the IM Configuration Management database are enabled, and the comparison keyword is `Match` or `Do not match`, you can specify the business group name in a path format.

If the integrated monitoring database and the IM Configuration Management database are disabled, and a comparison keyword other than `Match` and `Do not match` is selected, a business group name specified in a path format is treated as a host name.

If the `-ignorecasehost` option of the `jcoimdef` command is set to `ON`, and a comparison keyword other than `Regular expression` is selected, the character string is no longer case sensitive.

#2

`E.START_TIME` (start time), and `E.END_TIME` (end time) cannot be specified.

#3

If you have upgraded from version 10-50 or earlier of JP1/IM - Manager, this item is not output unless the integrated monitoring database has been updated using the `jimdbupdate` command.

## Example definition

```
B.ID IN 1
B.MESSAGE SUBSTR Warning
E.SOURCESERVER IN host1 host2 host3 host4
OR
B.ID IN 1
B.MESSAGE SUBSTR Error
E.SOURCESERVER IN host1 host2 host3 host4
EXCLUDE
E.SOURCESERVER IN host3
```

## ◆ System color definition file (systemColor.conf)

### Format

```
DESC_VERSION=file-version

#comment-line
[DEFAULT.BackgroundColor=color]
[DEFAULT.TextColor=color]

[SEVERITY.event-level.BackgroundColor=color]
[SEVERITY.event-level.TextColor=color]
:
```

### File

`systemColor.conf` (system color definition file)

`systemColor.conf.model` (model file for the system color definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\profile

For a logical host:

*shared-folder\jplcons\conf\console\profile*

In UNIX

For a physical host:

*/etc/opt/jplcons/conf/console/profile*

For a logical host:

*shared-directory/jplcons/conf/console/profile*

## Description

This file defines the color settings used on the **Monitor Events** page, **Severe Events** page, and **Search Events** page of the Event Console window.

## Execution permission

In Windows

The Administrators group and SYSTEM users must be able to reference the file.

In UNIX

Users with the root permissions must be able to reference the file.

## When the definitions are applied

When you select the **Display** check box in the **Coloring** section of the Preferences window, the events in an event list are colored according to the settings specified in the system color definition file.

JP1/IM - View colors the events according to the settings in the system color definition file specified when the user logs in.

If a user changes the settings in the system color definition file during the login process, the new settings take effect when the user restarts JP1/IM - View.

## Information that is specified

DESC\_VERSION=*file-version*

Indicates the system color definition file format version. The value to be specified is 1. If this value is omitted or another numeric value is specified, 1 is assumed.

*#comment-line*

A line beginning with a hash mark (#) is treated as a comment.

[DEFAULT.BackgroundColor=*color*]

Specifies the default background color. If the background color for the event level is not specified, or is specified for a JP1 event that does not match the specification of the background color, the background color specified for this parameter is applied. This parameter can be omitted. The background color is specified by the name of the color or by RGB values. The following table shows the correspondence between color name and RGB values.

| Color name | RGB value   |
|------------|-------------|
| black      | 0, 0, 0     |
| blue       | 0, 0, 255   |
| cyan       | 0, 255, 255 |

| Color name | RGB value     |
|------------|---------------|
| darkGray   | 64, 64, 64    |
| gray       | 128, 128, 128 |
| green      | 0, 255, 0     |
| lightGray  | 192, 192, 192 |
| magenta    | 255, 0, 255   |
| orange     | 255, 200, 0   |
| pink       | 255, 175, 175 |
| red        | 255, 0, 0     |
| white      | 255, 255, 255 |
| yellow     | 255, 255, 0   |

The color names are not case sensitive.

The range of RGB values that can be specified is from 0 to 255. The default value is white (255, 255, 255). RGB values are separated by a comma (,).

[DEFAULT.TextColor=*color*]

Specifies the text color of an event level if a color is not specified. This parameter can be omitted. The color name, the RGB values, and the range of RGB values are the same as DEFAULT.BackgroundColor=*color*. The color names are not case sensitive.

The default value is black (0, 0, 0).

[SEVERITY.*event-level*.BackgroundColor=*color*]

Specifies the background color of an event level. This parameter can be omitted. The color name, the RGB values, and the range of RGB values are the same as DEFAULT.BackgroundColor=*color*. The color names are not case sensitive.

The event levels that can be specified are Emergency, Alert, Critical, Error, Warning, Notice, Information, and Debug. The event levels are case sensitive.

[SEVERITY.*event-level*.TextColor=*color*]

Specifies the text color of the event level. This parameter can be omitted. The color name, the RGB values, and the range of RGB values are the same as DEFAULT.BackgroundColor=*color*. The color names are not case sensitive.

The event levels that can be specified are Emergency, Alert, Critical, Error, Warning, Notice, Information, and Debug. The event levels are case sensitive.

## Example definition

```
DESC_VERSION=1

DEFAULT.TextColor=black
DEFAULT.BackgroundColor=white

SEVERITY.Emergency.TextColor=white
SEVERITY.Emergency.BackgroundColor=red

SEVERITY.Alert.TextColor=white
SEVERITY.Alert.BackgroundColor=red
```

```

SEVERITY.Critical.TextColor=white
SEVERITY.Critical.BackgroundColor=red

SEVERITY.Error.TextColor=white
SEVERITY.Error.BackgroundColor=255,128,0

SEVERITY.Warning.TextColor=black
SEVERITY.Warning.BackgroundColor=yellow

```

## ◆ Definition file for extended event attributes

### Format

```

@encode character-encoding
@file type="definition-file-type", version="definition-format-version";
@product name="product-name";
@define-block type="event-attr-def";
block lang = "language-type", platform="platform-type"
attr name="attribute-name", title="display-item-name"[, type="attribute-disp
lay-type"];
...
@define-block-end;
@define-block type="event-attr-group-def";
block platform="platform-type"
group name="group-name", attrs="list-of-attribute-names";
...
@define-block-end;
@define-block type="event-attr-order-def";
block platform="platform-type"
order id="event-ID-definition-character-string", attrs="list-of-attribute-na
mes";
...
@define-block-end;

```

### File

The extension of a definition file for extended event attributes must be `.conf` (in lowercase).

`default.conf` (default definition file for extended event attributes)

`hitachi_xxxx.conf` (definition file for extended event attributes for a linked product)

`company-name_product-name_attr.conf` (user-defined definition file for extended event attributes)

*company-name* can be changed to *series-name\_product-name*. We recommend that you use the value specified for `PRODUCT_NAME` at the time of JP1 event issuance as the file name, with the forward slash (/) replaced by the underscore (\_). Because, `hitachi` is used for the default file name, use a name other than `hitachi` for *company-name*.

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\attribute\

For a logical host:

*shared-folder*\JP1Cons\conf\console\attribute\

In UNIX

For a physical host:

/etc/opt/jp1cons/conf/console/attribute/

For a logical host:

*shared-directory*/jp1cons/conf/console/attribute/

## Description

A definition file for extended event attributes defines the order for sorting the event attributes and the attribute names that are to be displayed in the Event Details window.

The following table describes the four types of definition files for extended event attributes.

Table 2–52: Types of definition files for extended event attributes

| No. | Type                              | Description                                                                                                                                |
|-----|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Default file                      | Definition of detailed event information about the basic attributes common to all events and the common information of extended attributes |
| 2   | Extended file                     | Definition of program-specific extended attributes                                                                                         |
| 3   | File provided by a linked product | Definition of program-specific information about the extended attributes of a linked product that issues JP1 events                        |
| 4   | User-defined file                 | User-specific information about user-defined extended attributes                                                                           |

The two file types listed under No. 1 and No. 3 above are stored in the definition file storage directory of JP1/IM. These two types of files are system standard definition files created when JP1/IM - Manager is installed, and they cannot be added to, changed, or deleted by the user.

To add new user- or program-specific information about extended attributes of JP1 events, you can create a definition file of type No. 2 or No. 4 above and store it in the storage directory.

For details about file type No. 2, see [Definition file for extended event attributes \(extended file\)](#) in *Chapter 2. Definition Files*.

## Creation timing

The following shows when the different types of definition files for extended event attributes are created.

| No. | File type                                  | When created                       |
|-----|--------------------------------------------|------------------------------------|
| 1   | default.conf                               | When JP1/IM - Manager is installed |
| 2   | hitachi_xxxx.conf                          | When JP1/IM - Manager is installed |
| 3   | <i>company-name_product-name_attr.conf</i> | When the user adds the file        |

## When the definitions are applied

The definitions in the definition file for extended event attributes take effect after either of the following occurs:

- JP1/IM - Manager is restarted.
- The command `jco_spmc_reload` is executed.

## Information that is specified

A definition file for extended event attributes defines the order for sorting event attributes and the attribute names that are to be displayed in the Event Details window of JP1/IM - View or the Event Detail window of the integrated operation viewer.

There are three types of definition files for extended event attributes:

- File for definition of detailed event information about the basic attributes common to all events and the common information for extended attributes (file included with the product: `default.conf`)
- File for definition of program-specific information about the extended attributes of a linked product that issues JP1 events (file included with the product: `hitachi_xxx.conf`)
- File for definition of user-specific information about user-defined extended attributes (created by the user)

The definition files for extended event attributes that are created when JP1/IM - Manager is installed are system standard definition files, and they cannot be added to, changed, or deleted by the user.

To add new user-specific information about extended attributes of JP1 events, you can create a definition file according to the naming rules described in [Table 2-2 Naming rules for definition files](#) and then store the file in the same definition file storage directory.

You should note the following about creating such a definition file:

- In JP1/IM - Manager for Linux, use UTF-8 encoding. In JP1/IM - Manager for OSs other than Linux, use Shift-JIS or EUC encoding.
  - If you mistakenly define the basic attributes or common information for the extended attributes in the definition file, the following is displayed if attributes (attribute name, item name, and attribute display type) are duplicated.
  - If only the attribute name or item name is duplicated: The attribute names and item names defined in each definition file are displayed.
  - If all attributes are duplicated: Specifications of the default file (`default.conf`) for the definition files for extended event attributes are ignored.

JP1/IM provides the `jcoattrfcheck` command for checking the contents of a definition file for extended event attributes. For details about this command, see [jcoattrfcheck](#) in *Chapter 1. Commands*.

You can specify the statements and blocks described in the table below in a definition file for extended event attributes.

**Table 2-53: Statements and blocks that can be specified in a definition file for extended event attributes**

| Statement or block | Description                                                  |
|--------------------|--------------------------------------------------------------|
| @encode statement  | Specifies the character encoding used in the definition file |
| @file statement    | Declares the definition file type and version                |
| @product statement | Declares product information in the definition               |

| Statement or block                               | Description                                                                        |
|--------------------------------------------------|------------------------------------------------------------------------------------|
| Definition block for extended event attributes   | Defines the display of event attributes                                            |
| Definition block for attribute groups            | Defines event attribute groups                                                     |
| Definition block for the attribute display order | Defines ID the order in which attributes are displayed in the Event Details window |

## Information that is specified (specification of character encoding)

### @encode

Specifies the character encoding that is to be used in the definition file for extended event attributes. The @encode statement can be omitted.

To create an additional file for definition file for extended event attributes, use an @encode statement to specify the character set for the definition file.

Item names are expressed in characters that can be represented in the character encoding specified in the @encode statement. In addition, the definition file for extended event attributes is stored in the character encoding specified in the @encode statement.

In the following circumstances, item names displayed in JP1/IM - View or the integrated operation viewer might be garbled:

- If the item name uses characters that cannot be represented in the character encoding specified in the @encode statement
- If the character encoding specified in the @encode statement does not match the character encoding in which the file was saved

If no @encode statement exists or if there is an error in the specified character set name that follows the @encode statement, the character set is determined automatically. However, depending on the content of the definition file, the character encoding might not be determined correctly.

The following character encodings can be specified:

- C
- EUCJIS
- SJIS
- UTF-8
- GB18030

### Note

If you use UTF-8 as the encoding to save a definition file, save the file without attaching a BOM (byte order mark).

An error is output in the following cases:

- A character encoding other than C, EUCJIS, SJIS, UTF-8 or GB18030 is specified
- The definition file does not begin with @encode.
- @encode is not followed by a character encoding value.

### Note

If you use a definition file for extended event attributes provided by another product, make sure that the character encoding specified in the @encode statement matches the character encoding used in the definition file. In addition, if you plan to transfer definition files, do not convert their character encoding.

## Information that is specified (rules for generating in-file statements)

### @file *statement*

Declares that this is a definition file for extended event attributes and that the version of the definition specification format is 0300. This statement is mandatory.

This statement must be on the first line of the file, or on the line following the @encode statement. If the statement is not specified on the first line, the integrity of operations cannot be guaranteed.

#### Syntax

```
@file type="extended-attributes-definition", version="0300";
```

### @product *statement*

Defines product information for the statements defined in the file.

When you specify this statement, note the following:

- The specified value must match the PRODUCT\_NAME JP1 event extended attribute. If this specification is omitted, the integrity of operations cannot be guaranteed.
- Prohibited characters and formatting irregularities are not checked during parsing; instead, the specified character string is used as is.

#### Syntax

```
@product name="product-name";
```

name="product-name"

The product name is a string of alphanumeric characters separated by a forward slash. It must be specified in one of the following formats:

- /company-name/series-name/product-name
- /company-name/product-name

#### Example definition

The following shows an example of definition information header statements:

```
@file type="extended-attributes-definition", version="0300";
@product name="/HITACHI/JP1/CentralConsole";
@define-block type="event-attr-def";
block lang="English", platform="NT";
attr name="E.SAMPLE_TIME", title="Sample time";
attr name="E.SAMPLE_HOST", title="Sample host";
attr name="E.SAMPLE_USER", title="Sample user";
@define-block-end;
```

## Information that is specified (rules for generating blocks in the definition file for extended event attributes)

This subsection describes the blocks that can be specified in a definition file for extended event attributes. If an invalid statement is specified in a block, an error is output but only the statement with the error is ignored.

### Definition block for extended event attributes

In the Event Details window, associate the event attribute name with its display item name (for all Japanese, English, and Chinese names). You can specify this block more than once in the definition file unless the blocks have the same key attribute (the value specified in the block statement discussed below).

When specifying multiple languages, if you specify an attribute name in an attr statement (described below) for any one language, you must specify that attribute name in an attr statement for every specified language.

### *Types of statements that can be specified*

You can specify the following statements in this block:

- `block` statement
- `attr` statement

### *Definition block for attribute groups*

This block groups event attributes that are defined in the definition blocks for extended event attributes. If you group multiple event attributes, you can avoid defining `order` statements repeatedly in the definition blocks for the attribute display order.

This block is optional.

### *Types of statements that can be specified*

You can specify the following statements in this block:

- `block` statement
- `group` statement

### *Definition block for the attribute display order*

Defines the order in which event attributes and attribute names are to be displayed when the details of each event are displayed.

### *Types of statements that can be specified*

You can specify the following statements in this block:

- `block` statement
- `order` statement

## **Information that is specified (rules for generating statements in a definition block for extended event attributes)**

### `block` statement

Defines block attributes. You can specify this statement only once at the beginning of a block.

#### *Syntax*

```
block lang=language-type, platform=platform-type;
```

#### `lang=language-type`

Declares the language used for the definition block for extended event attributes. You can specify one of the following languages:

- Japanese

Indicates that this is a definition for a Japanese language environment.

- English

Indicates that this is a definition for an English language environment.

- Chinese

Indicates that this is a definition for a Chinese language environment.

#### `platform=platform-type`

Specifies the platform to which the definition in the block is to be applied. You can specify the following values:

- `base`

The definition is applicable to all platforms.

If `base` is specified for the `platform` parameter, you must specify a comma (,) followed by `extended="false"`.

- *user-defined*

The definition is applicable to a user-defined platform. You must specify for *user-defined* a character string of alphanumeric characters. Note that this character string is not checked for errors.

The platform name specified in the `platform` parameter is compared with the PLATFORM JP1 event extended attribute; if they match, the specified information is subject to detailed information processing. If the platform name specified here is not found in the PLATFORM JP1 event extended attribute, the specified information is not processed. Note that if the PLATFORM extended attribute is not set at the time of JP1 event issuance, the system assumes that `base` is specified and executes file parsing.

#### Example definition

See the example definition for the `attr` statement below.

#### `attr` statement

Specifies an item name that is to be displayed in the attribute name column in the Event Details window and the type of the attribute value. You can specify this statement more than once in a block.

Note that this statement can be used to define only user-specific extended attribute information; the basic attributes and the common information of extended attributes are excluded. If the specified information is not user-specific extended attribute information, processing continues without outputting an error, but the specified information is displayed together with the provided standard definition information. For details about the standard definitions included with the product, see [Example definition](#) below.

#### Syntax

```
attr name=attribute-name, title=display-item-name [, type="elapsed_time/  
date_format:CLIENT"] ;
```

`name=attribute-name`

Specifies the name of an attribute.

The following table lists the attributes that can be displayed.

| No. | Specification format                 | Meaning of attribute     |
|-----|--------------------------------------|--------------------------|
| 1   | "B.SEQNO"                            | Serial number            |
| 2   | "B.IDBASE"                           | Event ID                 |
| 3   | "B.PROCESSID"                        | Source process ID        |
| 4   | "B.TIME"                             | Registered time          |
| 5   | "B.ARRIVEDTIME"                      | Arrived time             |
| 6   | "B.USERID"                           | Source user ID           |
| 7   | "B.GROUPID"                          | Source group ID          |
| 8   | "B.USERNAME"                         | Source user name         |
| 9   | "B.GROUPNAME"                        | Source group name        |
| 10  | "B.SOURCESERVER"                     | Source host              |
| 11  | "B.DESTSERVER"                       | Target event server name |
| 12  | "B.SOURCESEQNO"                      | Source serial number     |
| 13  | "B.MESSAGE"                          | Message                  |
| 14  | "B.SOURCEIPADDR"                     | Source IP address        |
| 15  | "E. <i>extended-attribute-name</i> " | Extended attribute       |

`title=display-item-name`

Specifies the character string that is to be displayed in the attribute name column in the Event Details window; the language specified in the `block` statement will be used.

`type="elapsed_time/date_format:CLIENT"`

Specifies the type and display format of the attribute value. The attribute value `elapsed_time` is a decimal character string indicating the elapsed time in seconds since UTC 1970-01-01 00:00:00. The display format `date_format:CLIENT` means that the value is to be displayed in the time format by using the time specified in the local time zone of the target viewer.

#### Example definition

This subsection presents an example of user-specific extended attribute information for JP1 events. This is an example of a definition block for extended event attributes that displays four extended attributes (user-specific information) listed in the following table for the platform W2K.

**Table 2–54: Example definition of a definition block for extended event attributes**

| Name displayed in the window | Extended attribute name (user-specific information) |
|------------------------------|-----------------------------------------------------|
| SAMPLE common attribute 1    | COMMON_ATTR1                                        |
| SAMPLE common attribute 2    | COMMON_ATTR2                                        |
| SAMPLE start attribute 1     | START_ATTR1                                         |
| SAMPLE start attribute 2     | START_ATTR2                                         |

```
@define-block type="event-attr-def";
block lang="English", platform="w2k";
attr name="E.COMMON_ATTR1",      title="SAMPLE common attribute 1";
attr name="E.COMMON_ATTR2",      title="SAMPLE common attribute 2";
attr name="E.START_ATTR1",       title="SAMPLE start attribute 1";
attr name="E.START_ATTR2",       title="SAMPLE start attribute 2";
@define-block-end;
```

## Information that is specified (rules for generating statements in a definition block for attribute groups)

### block statement

Defines block attributes. You can specify this statement only once at the beginning of a block.

When you define this statement, note the following:

- This block cannot contain the `lang` parameter.

#### Syntax

`block platform=platform-type;`

`platform=platform-type`

Specifies the platform to which the definition in the block is to be applied. You can specify the following values:

| Specifiable value | Description                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "base"            | Use the value to enable the definition for all platforms.<br>If <code>base</code> is specified for the <code>platform</code> parameter, you must specify a comma (,) followed by <code>extended="false"</code> . |

| Specifiable value       | Description                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| " <i>user-defined</i> " | The definition is enabled for a user-defined platform. You must specify for <i>user-defined</i> a one-byte alphanumeric character string. Note that this character string is not checked for errors. |

The platform name specified in the `platform` parameter is compared with the PLATFORM JP1 event extended attribute; if they match, the specified information is subject to detailed information processing. If the platform name specified here is not found in the PLATFORM JP1 event extended attribute, the specified information is not processed. Note that if the PLATFORM extended attribute is not set at the time of JP1 event issuance, the system assumes that `base` is specified and executes file parsing.

#### Example definition

See the example definition for the `group` statement below.

#### group statement

Groups attributes by assigning a name to a list of attributes that are to be displayed in the Event Details window. You can specify this statement more than once in a block.

#### Syntax

```
group name=group-name, attrs=list-of-attribute-names;
```

`name=group-name`

Specifies a name for the list of attribute names. Express the name using from 1 to 32 alphanumeric characters. This name is not case sensitive. You can use this name in the `order` block in the definition file.

`attrs=list-of-attribute-names`

Specifies a list of one or more attributes that are to be grouped. When multiple attributes are listed in this parameter, they are displayed in the Event Details window in the order specified here. The specification format is as follows:

- To specify only one attribute: `attrs="E.A0"`
- To specify multiple attributes: `attrs="E.A0|E.A1"`

Note that you can specify only user-specific extended attribute information. If you have specified a basic attribute or a common information item for an extended attribute, the specified attribute value is displayed more than once in the Event Details window.

#### Example definition

This example shows the definitions of basic attributes and user-specific information for JP1 event extended attributes. These definitions are provided as standard in the definition file for extended event attributes.

```
@define-block type="event-attr-group-def";
block platform="base", extended="false";
group name="BASE", attrs="B.GROUPID|B.GROUPNAME|B.IDBASE|B.PROCESSID|B.
SEQNO|B.SOURCEIPADDR|
B.SOURCESEQNO|B.SOURCESERVER|B.TIME|B.USERID|B.USERNAME|B.ARRIVEDTIME";
group name="COMMON", attrs="E.SEVERITY|E.USER_NAME|E.PRODUCT_NAME|E.OBJ
ECT_TYPE|E.OBJECT_NAME|
E.ROOT_OBJECT_TYPE|E.ROOT_OBJECT_NAME|E.OBJECT_ID|E.OCCURRENCE|
E.START_TIME|E.END_TIME|E.RESULT_CODE";
@define-block-end;
```

## Information that is specified (rules for generating statements in a definition block for the attributes display order)

### block statement

Defines the block attribute that depends on the definition block for the attribute display order. You can specify this statement only once at the beginning of a block.

When you define this statement, note the following:

- This block cannot contain the `lang` parameter.

#### Syntax

```
block platform=platform-type;
```

*platform=platform-type*

Specifies the platform to which the definition in the block is to be applied. You can specify the following values:

Table 2–55: Specifiable platforms

| Specifiable value | Description                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "base"            | Use the value to enable the definition for all platforms.<br>If <code>base</code> is specified for the <code>platform</code> parameter, you must specify a comma (,) followed by <code>extended="false"</code> . |
| "user-defined"    | The definition is enabled for a user-defined platform. You must specify for <i>user-defined</i> a one-byte alphanumeric character string. Note that this character string is not checked for errors.             |

The platform name specified in the `platform` parameter is compared with the PLATFORM JP1 event extended attribute; if they match, the specified information is subject to detailed information processing. If the platform name specified here is not found in the PLATFORM JP1 event extended attribute, the specified information is not processed. Note that if the PLATFORM extended attribute is not set at the time of JP1 event issuance, the system assumes that `base` is specified and executes file parsing.

#### Example definition

See the example definition for the `order` statement below.

### order statement

Defines by ID the attributes to be displayed in the Event Details window and their sort order. You can specify this statement more than once in a block.

#### Syntax

```
order id=event-ID-definition-character-string, attrs=list-of-attribute-names;
```

*id=event-ID-definition-character-string*

Specifies one event ID for which attributes are to be displayed in the order specified in the `attrs` parameter.

The specification format is as follows:

```
id="200"
```

Express an event ID using from 1 to 8 hexadecimal characters. If a specified event ID consists of fewer than 8 characters, there is no need to add leading zeros to pad it out to 8 characters. The alphabetic characters in the hexadecimal character string (a to f) are not case sensitive.

A range of IDs cannot be specified.

*attrs=list-of-attribute-names*

Specifies a list of the attributes, the groups, or both that are to be displayed. When multiple items are specified in this parameter, they are displayed in the Event Details window in the order specified here.

The specification format is as follows:

- To specify only one item: `attrs="E.A0"`
- To specify multiple items: `attrs="E.A0|E.A1|GROUP1"`

As is the case with the group statement, you can specify only user-specific extended attributes. If you have specified a basic attribute or common extended attribute, the specified attribute value will be displayed more than once in the Event Details window.

#### *Example definition*

This example definition displays the BASE and COMMON groups for event ID 00001000:

```
@define-block type="event-attr-order-def";
block platform="base", extended="false";
order id="00001000", attrs="BASE|COMMON"
@define-block-end;
```

## Example definition of a definition file for extended event attributes

```
@encode UTF-8
@file type="extended-attributes-definition", version="0300";
@product name="/HITACHI/JP1/SAMPLE";
@define-block type="event-attr-def";
block platform="base", lang="English", extended="false";
attr name="E.SAMPLE_CLUSTER_NAME", title="Cluster name";
attr name="E.SAMPLE_PRINT_SERVER_NAME", title="Print server name";
attr name="E.SAMPLE_PRINTER_NAME", title="Printer name";
attr name="E.SAMPLE_PORT_NAME", title="Port name";
@define-block-end;
@define-block type="event-attr-group-def";
block platform="base", extended="false";
group name="_PRINTER_INFO",
attrs="E.SAMPLE_PRINT_SERVER_NAME|E.SAMPLE_PRINTER_NAME";
group name="_CLUSTER_INFO", attrs="E.SAMPLE_CLUSTER_NAME|E.SAMPLE_PORT_NAME";
@define-block-end;
@define-block type="event-attr-order-def";
block platform="base", extended="false";
order id="00003100", attrs="_PRINTER_INFO";
order id="00003101", attrs="_CLUSTER_INFO";
order id="00003102", attrs="_PRINTER_INFO|_CLUSTER_INFO";
@define-block-end;
```

## Definition file for extended event attributes that is included with the product

Shown below are the definitions of the basic attributes and the common information for extended attributes for JP1 events. These definitions are included with the product as the definition file for extended event attributes.

```
@define-block type="event-attr-def";
block lang="English", platform="base", extended="false";
attr name="B.SEQNO", title="Serial number";
attr name="B.IDBASE", title="Event ID";
attr name="B.PROCESSID", title="Source process ID";
attr name="B.TIME", title="Registered time", type="elapsed_time_
in_milli/date_format:CLIENT";
attr name="B.ARRIVEDTIME", title="Arrival time", type="elapsed_time/dat
```

```

e_format:CLIENT";
attr name="B.USERID", title="Source user ID";
attr name="B.GROUPID", title="Source group ID";
attr name="B.USERNAME", title="Source user name";
attr name="B.GROUPNAME", title="Source group name";
attr name="E.JP1_SOURCEHOST", title="Event source host name";
attr name="B.SOURCESERVER", title="Event-issuing server name";
attr name="B.SOURCEIPADDR", title="Source IP address";
attr name="B.SOURCESEQNO", title="Source serial number";
attr name="E.SEVERITY", title="Event level";
attr name="E.USER_NAME", title="User name";
attr name="E.PRODUCT_NAME", title="Product name";
attr name="E.OBJECT_TYPE", title="Object type";
attr name="E.OBJECT_NAME", title="Object name";
attr name="E.ROOT_OBJECT_TYPE", title="Root object type";
attr name="E.ROOT_OBJECT_NAME", title="Root object name";
attr name="E.OBJECT_ID", title="Object ID";
attr name="E.OCCURRENCE", title="Occurrence";
attr name="E.START_TIME", title="Start time", type="elapsed_time/date_
format:CLIENT";
attr name="E.END_TIME", title="End time", type="elapsed_time/date_for
mat:CLIENT";
attr name="E.RESULT_CODE", title="Result code";
attr name="E.JP1_GENERATE_SOURCE_SEQNO", title="Relation Event serial number
";
attr name="E.JP1_GENERATE_NAME", title="Correlation event generatio
n condition name";
attr name="E.@JP1IM_ORIGINAL_SEVERITY", title="Original severity level";
attr name="E.JP1_IMSUPPRESS_ID", title="Suppressed event ID";
attr name="E.JP1_IMSUPPRESS_NAME", title="Repeated event condition name";
attr name="E.JP1_TRAP_ID", title="Monitoring ID";
attr name="E.JP1_TRAP_NAME", title="Log file trap name";
attr name="E.@JP1IM_CHANGE_MESSAGE_NAME", title="Display message change d
efinition";
attr name="E.JP1_IMCOMEXCLUDE_ID", title="Common exclude conditions group
ID";
attr name="E.JP1_IMCOMEXCLUDE_NAME", title="Common exclude conditions group
name";
attr name="E.JP1_IMCOMEXCLUDE_TARGET", title="Common exclude conditions grou
p target-for-exclusion";
attr name="E.SUGGESTION_ID", title="Suggestion ID";
attr name="E.TREE_SID", title="SID of the tree";
@define-block-end;

```

## ◆ Definition file for extended event attributes (extended file)

### Format

```

[@encode character-encoding]
@file type="extended-attributes-definition", version="0300";
@define-block type="event-attr-def";
attr name="attribute-name", title="item-name";
...
@define-block-end;

```

## File

`template_extend_attr_ja.conf` (Japanese extended file)

`template_extend_attr_ja.conf.model` (model file for the Japanese extended file)

`template_extend_attr_en.conf` (English extended file)

`template_extend_attr_en.conf.model` (model file for the English extended file)

`template_extend_attr_zh.conf` (Chinese extended file)

`template_extend_attr_zh.conf.model` (model file for the Chinese extended file)

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\attribute\extend

For a logical host:

*shared-folder*\JP1Cons\conf\console\attribute\extend

In UNIX

For a physical host:

/etc/opt/jplcons/conf/console/attribute/extend

For a logical host:

*shared-directory*/jplcons/conf/console/attribute/extend

## Description

The definition file for extended event attributes (extended file) defines program-specific extended attributes to be displayed as item names on the screen of JP1/IM - View or the integrated operation viewer or output as item names in event reports.

Note that the definition file included with JP1/IM - Manager is prefixed with `template_`. Rename the file to `extend_attr_ja.conf` before you use it.

For details about a definition file for extended event attributes that is not an extended file, see [Definition file for extended event attributes](#) in *Chapter 2. Definition Files*.

## Creation timing

The files are created when JP1/IM - Manager is installed.

## When the definitions are applied

The definitions in the definition file for extended event attributes (extended file) take effect after either of the following occurs:

- JP1/IM - Manager is restarted.
- The command `jco_spmc_reload` is executed.

Note that you must restart JP1/IM - View or the integrated operation viewer if the definition is applied while JP1/IM - View or the integrated operation viewer are connected.

## Information that is specified

The definition file for extended event attributes (extended file) defines program-specific extended attributes to be displayed as item names on the screen or output as item names in event reports. The extended files are JP1/IM - Manager definition files that are defined for each language used by JP1/IM - Manager.

If you use extended files for multiple languages in JP1/IM - Manager, the same attribute names must be specified in all the extended files. Because the attributes to be displayed in JP1/IM - View or the integrated operation viewer are uniquely determined for the entire system, it is not possible to display different attributes for different JP1/IM - Views or the integrated operation viewer in each language.

If there is a mismatch in the attribute names specified in the extended files, the warning message KAVB5820-W will be output when you check the extended files using the `jcoattrfcheck` command. In addition, attributes not specified in the extended files might appear in JP1/IM - View or the integrated operation viewer. For example, if the attribute `E.SYSTEM` is specified only in the English extended file, `E.SYSTEM` will also appear in the Japanese and Chinese JP1/IM - Views. In this case, the item name of `E.SYSTEM` displayed in the Japanese and Chinese JP1/IM - Views will be identical to the attribute name, namely `E.SYSTEM`.

JP1/IM provides the `jcoattrfcheck` command for checking the contents of a definition file for extended event attributes (extended file). For details about this command, see [jcoattrfcheck](#) in *Chapter 1. Commands*.

You can specify the statements and blocks described in the table below in a definition file for extended event attributes (extended file).

Table 2-56: Statements and blocks that can be specified in a definition file for extended event attributes (extended file)

| Statement or block                             | Description                                                  |
|------------------------------------------------|--------------------------------------------------------------|
| <code>@encode</code> statement                 | Specifies the character encoding used in the definition file |
| <code>@file</code> statement                   | Declares the definition file type and version                |
| Definition block for extended event attributes | Defines the display of event attributes                      |

Any statement or block that is not listed in the table above is ignored. If a definition file for extended event attributes (extended file) includes an invalid element, the invalid line is ignored while other valid lines work successfully. However, an error is issued if an invalid element is found in a statement that can be read from a definition file for extended event attributes (non-extended file) but cannot be read from a definition file for extended event attributes (extended file), for example, the `block` statement (`block lang=""`;). For details about definition files for extended event attributes (non-extended files), see [Definition file for extended event attributes](#) in *Chapter 2. Definition Files*.

## Information that is specified (specification of character encoding)

### `@encode`

Specifies the character encoding that is to be used in the definition file for extended event attributes (extended file).

Item names will be expressed in characters that can be represented in the character encoding specified in the `@encode` statement. In addition, the definition file for extended event attributes (extended file) will be saved in the character encoding specified in the `@encode` statement.

In the following circumstances, item names displayed in JP1/IM - View or the integrated operation viewer might be garbled:

- If the item name uses characters that cannot be represented in the character encoding specified in the `@encode` statement
- If the character encoding specified in the `@encode` statement does not match the character encoding in which the file was saved

If no `@encode` statement exists or if there is an error in the specified character set name that follows the `@encode` statement, the character set is determined automatically. However, depending on the content of the definition file, the character encoding might not be determined correctly.

The following character encodings can be specified.

**Table 2–57: Definition file character encodings that can be specified**

| No | Character encoding of file | Can be specified?   |                |
|----|----------------------------|---------------------|----------------|
|    |                            | OS other than Linux | Linux          |
| 1  | C                          | Y                   | Y              |
| 2  | EUCJIS                     | Y                   | N              |
| 3  | SJIS                       | Y                   | Y <sup>#</sup> |
| 4  | UTF-8                      | Y                   | Y              |
| 5  | GB18030                    | Y                   | Y              |

Legend:

Y: Can be specified

N: Cannot be specified

#

Can be specified only in SUSE Linux.

*Note:*

If you use UTF-8 as the encoding to save a definition file, save the file without attaching a BOM (byte order mark).

An error is output in the following cases:

- A character encoding other than C, EUCJIS, SJIS, UTF-8, or GB18030 is specified
- The definition file does not begin with `@encode`
- `@encode` is not followed by a character encoding value

## Information that is specified (rules for generating in-file statements)

### `@file statement`

Declares that this is a definition file for extended event attributes (extended file) and that the version of the definition specification format is 0300. This statement is required.

This statement must be on the first line of the file. If the statement is not specified on the first line, the integrity of operations cannot be guaranteed.

Syntax

```
@file type="extended-attributes-definition", version="0300";
```

## Information that is specified (rules for generating blocks in the definition file for extended event attributes)

This subsection describes the blocks that can be specified in a definition file for extended event attributes (extended file). If an invalid statement is specified in a block, an error is output but only the statement with the error is ignored.

## Definition block for extended event attributes

This block associates the event attribute name with its display item name. You can specify this block only once within the definition file. If you specify more than one definition block for extended event attributes, no error or warning is output, but the second and subsequent blocks are ignored.

### Types of statements that can be specified

You can specify the following statements in this block:

`attr statement`

## Information that is specified (rules for generating statements in a definition block for extended event attributes)

### `attr statement`

Specifies the name of a program-specific extended attribute and the item name corresponding to that attribute, which is to be displayed on the screen or in event reports. You can specify this statement up to 100 times in a block. If you specify more than 100 `attr` statements, message KAVB5803-W will be output when you check the definition file with the `jcoattrfcheck` command.

### Syntax

```
attr name=attribute-name, title=item-name;
```

`name=attribute-name`

Specifies the name of the extended attribute. The format is as follows:

`"E.extended-attribute-name"`

For the attribute name, you can specify a name with a maximum length of 32 bytes that begins with an uppercase letter and consists of uppercase letters, numeric characters, and the underscore (`_`).

If you specify an extended attribute name that exceeds 32 bytes, message KAVB5803-W will be output when you check the definition file with the `jcoattrfcheck` command or execute the `jcoevtreport` command. In addition, message KAVB5822-W will be output when the definition file for extended event attributes (extended file) is loaded when JP1/IM - Manager starts or the `jco_spmc_reload` command is executed.

Only a program-specific extended attribute can be specified. However, you cannot specify attributes that overlap with the extended attributes specified in the standard definition file for extended event attributes (`default.conf`), such as the event source host name (`E.JP1_SOURCEHOST`) or the log file trap name (`E.JP1_TRAP_NAME`). If you specify extended attributes that overlap with the standard definition file for extended event attributes (`default.conf`), the item names specified in the standard file will be applied.

If you specify extended attributes that overlap with the standard definition file for extended event attributes (`default.conf`), message KAVB5802-W<sup>#</sup> will be output after the definition file for extended event attributes (extended file) is loaded when you execute the `jcoevtreport` or `jcoattrfcheck` command. The `jcoevtreport` command proceeds by ignoring overlapping attributes specified in the definition file for extended event attributes (extended file). In addition, message KAVB5822-W will be output after the definition file for extended event attributes (extended file) is loaded when you restart JP1/IM - Manager or execute the `jco_spmc_reload` command. JP1/IM - Manager proceeds by ignoring overlapping attributes specified in the definition file for extended event attributes (extended file).

If you specify a basic attribute (`B.attribute-name`) or an IM attribute (`E.@attribute-name`), or some other attribute that is not an extended attribute (`E.attribute-name`), message KAVB5821-W<sup>#</sup> will be output after the definition file for extended event attributes (extended file) is loaded when you execute the `jcoevtreport` or `jcoattrfcheck` command. In addition, message KAVB5822-W will be output after the definition file for extended event attributes (extended file) is loaded when you restart JP1/IM - Manager or execute the `jco_spmc_reload` command.

#: When the `jcoevtreport` command generates reports successfully or when the `jcoattrfcheck` command checks the definition file completely, the return value of the commands is 0 (normal end), regardless of whether message KAVB5802-W or KAVB5821-W was output.

If you use extended files for multiple languages in JP1/IM - Manager, all the attribute names specified in the definition files for extended event attributes (extended files) must match. Otherwise, message KAVB5820-W will be output after the definition file for extended event attributes (extended file) is loaded when you execute the `jcoevtreport` or `jcoattrfcheck` command. In addition, message KAVB5822-W will be output after the definition file for extended event attributes (extended file) is loaded when you restart JP1/IM - Manager or execute the `jco_spmd_reload` command.

`title=item-name`

Defines the item name of the program-specific extended attribute. *item-name* is expressed in characters that can be represented in the character encoding specified in the `@encode` statement. *item-name* might appear garbled in JP1/IM - View if it uses characters that cannot be represented in the character encoding specified in the `@encode` statement.

In addition, *item-name* might appear garbled in CSV files if it uses characters that cannot be represented in the character encoding of the report output by the `jcoevtreport` command.

Specify a character string that will serve as the program-specific extended attribute's item name for display on the screen and output in event reports. Half-width kana characters and the comma (,) cannot be used in this parameter. If half-width kana characters and the comma (,) are specified in the character string, they will not be output correctly.

The maximum length of *item-name* is 255 bytes. If you specify more than 255 bytes for *item-name*, message KAVB5803-W will be output when you check the definition file with the `jcoattrfcheck` command or execute the `jcoevtreport` command. In addition, message KAVB5822-W will be output after the definition file for extended event attributes (extended file) is loaded when you restart JP1/IM - Manager or execute the `jco_spmd_reload` command.

*Note:*

If you specify program-specific extended attributes in the definition file for extended event attributes (extended file) that overlap with the attributes in the standard definition file for extended event attributes (`default.conf`), the program-specific extended attribute item names specified in the standard definition file for extended event attributes (`default.conf`) will be displayed in the list of events in the Event Console window and will be output in the CSV header that is output with event reports.

## Example definition

The following shows an example of a definition file for extended event attributes (extended file):

```
@encode UTF-8
@file type="extended-attributes-definition", version="0300";
@define-block type="event-attr-def";
attr name="E.SYSTEM",      title="System name";
attr name="E.ROLE",       title="Server role";
@define-block-end;
```

## ◆ Definition file for object types

### Format

```
@encode character-encoding  
[comment]  
[ObjectType]  
definition-block [comment]  
[End]  
[comment]
```

### File

*company-name\_product-name\_company-name\_product-name\_obj.en* (definition file for object types)

*company-name* can be changed to *series-name\_product-name*. We recommend that you use the value specified for `PRODUCT_NAME` at the time of JP1 event issuance as the file name, with the forward slash (/) replaced by the underscore (\_). Because `hitachi` is used for the default file name, use a name other than `hitachi` for *company-name*.

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\object\_type\

For a logical host:

*shared-folder*\jplcons\conf\console\object\_type\

In UNIX

For a physical host:

/etc/opt/jplcons/conf/console/object\_type/

For a logical host:

*shared-directory*/jplcons/conf/console/object\_type/

### Description

The definition file for object types defines the object types and root object types that are displayed in **Object type** and **Root object type** in the following JP1/IM - View windows:

- Severe Event Definitions window
- Event Acquisition Settings window
- Common Exclusion-Conditions Settings window
- Common Exclusion-Condition Settings (Extended) window
- Repeated Event Condition Settings window
- Event Search Conditions window
- Settings for View Filter window
- Detailed Settings for Event Receiver Filter window
- Action Parameter Detailed Definitions window
- Severity Change Definition Settings window (Add Severity Change Definition Settings window)

- Display Message Change Definition Settings window (Add Display Message Change Definition Settings window)

For JP1/IM - Manager for Linux, the file must use UTF-8 encoding, and for JP1/IM - Manager for an OS other than Linux, the file must use Shift-JIS or EUC encoding.

If multiple files contain the same object type, the integrity of operations is not guaranteed.

## When the definitions are applied

The definition takes effect after JP1/IM - View is restarted.

## Information that is specified

`@encode` *character-encoding*

Specifies the character encoding that is to be used in the definition file for object types.

To create an additional file for definition file for object types, use an `@encode` statement to specify the character set for the definition file.

Item names will be expressed in characters that can be represented in the character encoding specified in the `@encode` statement. In addition, the definition file for object types will be saved in the character encoding specified in the `@encode` statement.

In the following circumstances, item names displayed in JP1/IM - View might be garbled:

- If the item name uses characters that cannot be represented in the character encoding specified in the `@encode` statement
- If the character encoding specified in the `@encode` statement does not match the character encoding in which the file was saved

If no `@encode` statement exists or if there is an error in the specified character set name that follows the `@encode` statement, the character set is determined automatically. However, depending on the content of the definition file, the character encoding might not be determined correctly.

The specifiable character encodings are as follows:

- C
- EUCJIS
- SJIS
- UTF-8
- GB18030

Note

If you use UTF-8 as the encoding to save a definition file, save the file without attaching a BOM (byte order mark).

An error is output in the following cases:

- A character encoding other than C, EUCJIS, SJIS UTF-8 or GB18030 is specified
- The definition file does not begin with `@encode`.
- `@encode` is not followed by a character encoding specification.

[*comment*]

Specifies a comment as a character string that begins with a hash mark (#) and does not contain a linefeed code.

[ObjectType]

Specify [ObjectType] and [End] as is, including the square brackets.

*definition-block* [*comment*]

A definition block consists of an extended attribute value and a list display character string. The extended attribute value is a character string that is stored in the object type or root object type. The list display character string is a character string that is displayed in a list drop-down list.

[End]

Specify [End] as is, including the square brackets.

When you define this information, note the following:

- The object type (extended attribute value) cannot contain spaces.
- For list display character strings, specify the extended attribute value itself instead of characters.

## Example definition

The following shows an example of a definition file for object types:

```
@encode UTF-8
[ObjectType]
# Extended attribute value, List display character string Comment
ACTION, ACTION // action
ACTIONFLOW, ACTIONFLOW // action flow
BATCHQUEUE, BATCHQUEUE // batch queue
JOB, JOB // job
JOBNET, JOBNET // jobnet
MEDIA, MEDIA // media
PRINTER, PRINTER // printer
PRINTJOB, PRINTJOB // print job
PRINTQUEUE, PRINTQUEUE // pipe queue
PROCESS, PROCESS // process
RESTORE, RESTORE // restore
[End]
```

## ◆ Common-exclusion-conditions extended definition file

### Format

```
DESC_VERSION=file-version
# comment-line
def conditions-group-name
  [cmt comment]
  id conditions-group-ID
  [valid {true | false}]
  [ex-target Exclusion target]
  [date start-date-end-date]
  [rttime start-time-end-time]
  [week day-of-week]
  cnd
    event-condition
  end-cnd
end-def

def conditions-group-name-2
```

```
...
end-def
:
```

## File

## Description

This file defines the event conditions or the applicable period of the extended-mode common exclusion-conditions.

Use the language encoding that is used by JP1/IM - Manager to specify this file.

In the following cases, the backup file for the common-exclusion-conditions extended definition file is output as `common_exclude_filter_backup.conf`.

- An error is still found in a regular expression after the operation mode of common exclusion-conditions is switched from the basic mode to the extended mode by the `jcochcefmode` command.
- When the operation mode is changed from the extended mode to the basic mode.

For details about the `jcochcefmode` command and the backup file for the common-exclusion-conditions extended definition file, see [jcochcefmode](#) in *Chapter 1. Commands*.

Note that if the event acquisition filter (for compatibility) is used, common exclusion-conditions cannot be used. If the event acquisition filter (for compatibility) is used, use the `jcochafmode` command to switch to event acquisition filters. For details about the `jcochafmode` command, see [jcochafmode \(UNIX only\)](#) in *Chapter 1. Commands*.

The maximum size of the common-exclusion-conditions extended definition file is 15 megabytes in Shift JIS code.

Note that the maximum size is the total of the common-exclusion-conditions extended definition file and the additional common exclusion conditions. Therefore, if you write definitions so that the common-exclusion-conditions extended definition file is 15 megabytes in JIS code, you cannot add the additional common exclusion definition conditions.

## When the definitions are applied

The definitions take effect when the `-ef` option of the `jcochfilter` command is specified. For details about the `jcochfilter` command, see [jcochfilter](#) in *Chapter 1. Commands*.

## Information that is specified

`DESC_VERSION=`*file-version*

Indicates the version of the extended definition file for the common exclusion-conditions. 1 or 2 can be specified. If this parameter is omitted, 1 is assumed.

#### # *comment-line*

A line beginning with a hash mark (#) is treated as a comment.

#### def to end-def (definition block)

These are the start and end parameters of the definition for the extended-mode common exclusion-conditions.

The block from def to end-def can be omitted. After def, specify the name of the extended-mode common exclusion-conditions group. If you specify "def  $\Delta\Delta\Delta$ conditions-group-name-1  $\Delta\Delta\Delta$ conditions-group-name-2  $\Delta\Delta\Delta$ ", " $\Delta\Delta\Delta$ conditions-group-name-1  $\Delta\Delta\Delta$ conditions-group-name-2  $\Delta\Delta\Delta$ " will be the definition name ( $\Delta$  indicates a space).

Specify *conditions-group-name* so that it is unique within the common-exclusion-conditions extended definition file. You can specify a character string of 1 to 50 bytes in Shift JIS. The characters you can specify are characters other than control characters (0x00 to 0x1F, 0x7F to 0x9F).

A maximum of 2,500 definition blocks can be written.

Note that the maximum number is the total of the number of definition blocks written in the common-exclusion-conditions extended definition file and the number of additional common exclusion condition groups. Therefore, if you write 2,500 definition blocks in the common-exclusion-conditions extended definition file, you cannot create an additional common exclusion condition group.

#### cmt *comment*

Provides an explanation of the extended-mode common exclusion-conditions. This parameter can be omitted.

Specify a character string of 1 to 1,024 bytes in Shift JIS code for the comment. Specifiable characters are other than control characters (0x00 to 0x1F, 0x7F to 0x9F).

#### id *conditions-group-ID*

Specifies the conditions group ID of the extended-mode common exclusion-conditions. You can specify a value from 0 to the maximum number of definitions minus 1. This parameter cannot be omitted.

The IDs you can specify for the id parameter is from 0 to 2,499.

#### valid {true | false}

Specifies whether to enable the extended-mode common exclusion-conditions.

This parameter is not case sensitive. If this parameter is omitted, true is assumed.

#### ex-target *Exclusion target*

Specifies the target of the exclusion. Specify the character string *action* in the *exclusion-target* to exclude JP1 events that satisfy a common exclusion-condition from automated-action execution. The character string is not case sensitive. If this parameter is omitted, JP1 events that satisfy a common exclusion-condition are excluded from the target to be collected. Only one occurrence of this parameter is allowed for each definition block. Note that this parameter is available only when the version of the common exclusion-conditions extended definition file is 2.

#### date *start-date-end-date*

Specifies the period during which the extended-mode common exclusion-conditions apply. This parameter can be omitted. Specify this parameter in the following format:

date $\Delta$ YYYYMMDD-YYYYMMDD

Legend:  $\Delta$ : A space

The specifiable period is from 1970/01/01 to 2099/12/31.

If this parameter is omitted, the extended-mode common exclusion-conditions always apply.

If the start date is omitted, the extended-mode common exclusion-conditions apply from the time they are defined until the end date. To omit the start date, specify only the end date in the following format:

date $\Delta$ -YYYYMMDD

Legend:  $\Delta$ : A space

If the end date is omitted, the conditions apply continuously from the start date. To omit the end date, specify only the start date using one of the following formats:

dateΔYYYYMMDD

dateΔYYYYMMDD-

Legend: Δ: A space

For details about the applicable period, see *4.2.7 Common exclusion-conditions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

**rtime** *start-time-end-time*

Specifies the time during which the extended-mode common exclusion-conditions apply. This parameter can be omitted. Specify this parameter in the following format:

rtimeΔHHMM-HHMM

Legend: Δ: A space

If this parameter is omitted, 9:00 is assumed as the start time, and the end time will be 24 hours after that time. The start time cannot be omitted. If the end time is omitted, the conditions apply for 24 hours from the start time.

To omit the end time, specify only the start time using one of the following formats:

rtimeΔHHMM

rtimeΔHHMM-

Legend: Δ: A space

The time you can specify for the start time and the end time is from 00:00 to 23:59.

If you specify an end time earlier than the start time, the end time is treated as the time of the following day. Alternatively, if the same time is specified for the start time and the end time, the end time is treated as the time of the following day.

The following table lists the omission patterns of the parameter end time.

**Table 2–58: Omission patterns of the end time for the rtime parameter**

| No. | Omission pattern          | Description                                  |
|-----|---------------------------|----------------------------------------------|
| 1   | rtimeΔstart-time          | Applied within 24 hours from the start time  |
| 2   | rtimeΔstart-time-         |                                              |
| 3   | rtimeΔstart-time-end-time | Applied from the start date to the end date. |

Legend:

Δ: Single-byte space

Specify the start time and the end time in the *HHMM* format. Specify the hour for *HH*, and the minute for *MM*.

The application period includes the start time but not the end time. For example, if you specify Monday, and set the start time to 21:00 and the end time to 03:00, the application period is from 21:00:00 on Monday through 02:59:59 on Tuesday (the following day).

For details about the applicable period, see *4.2.7 Common exclusion-conditions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

**week** *day-of-week*

Specifies a day of the week on which the extended-mode common exclusion-conditions apply. This parameter can be omitted. To specify two or more days of the week, separate the days by a comma ( , ). Use the following format:

weekΔ0, 1, 2, 3, 4, 5, 6

Legend: Δ: A space

Days of the week correspond to the following numeric values:

- Sunday: 0

- Monday: 1
- Tuesday: 2
- Wednesday: 3
- Thursday: 4
- Friday: 5
- Saturday: 6

If the day of the week is omitted, all days of the week are assumed.

For details about the applicable period, see 4.2.7 *Common exclusion-conditions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

`cnd` to `end-cnd` (event condition block)

These parameters mark the start and end of the block that specifies the event conditions of the extended-mode common exclusion-conditions. An event condition block must be specified in a definition block. It cannot be omitted. A tab or a space before or after the `cnd` and `end-cnd` parameters is ignored.

You cannot specify multiple event condition blocks for one definition block.

#### *event-condition*

Specifies the conditions for excluding JP1 events by means of the extended-mode common exclusion-conditions. You can specify from 0 to 256 event conditions for the event condition block. The event conditions are connected with the AND condition. The following shows how JP1 event conditions are specified:

*attribute-name*Δ*comparison-keyword*Δ*operand*

Legend: Δ: A space

Note that a line that contains only spaces and tabs is ignored, and processing continues.

#### *attribute-name*

Specifies the name of the attribute you want to compare. To specify a basic attribute, prefix the name with `B.`. To specify an extended attribute (common information) or an extended attribute (program-specific information), prefix the name with `E.`. The attribute name is case sensitive.

The following table lists and describes the combinations of attribute names and comparison keywords and the operands that can be specified.

**Table 2–59: Combinations of attribute names and comparison keywords and the operands that can be specified**

| No. | Item                    | Attribute name        | Comparison keyword                                                                | Operand                                                                                                                                                                                                                                                                                                     |
|-----|-------------------------|-----------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Event ID                | <code>B.ID</code>     | <ul style="list-style-type: none"> <li>• Match</li> <li>• Do not match</li> </ul> | <p>Specifies the event ID of a JP1 event.</p> <ul style="list-style-type: none"> <li>• A maximum of 100 event IDs can be specified.</li> <li>• Specify the event IDs in hexadecimal notation.</li> <li>• Event IDs are not case sensitive.</li> <li>• The permitted range is from 0 to 7FFFFFFF.</li> </ul> |
| 2   | Reason for registration | <code>B.REASON</code> | <ul style="list-style-type: none"> <li>• Match</li> <li>• Do not match</li> </ul> | <p>Specifies the reason for registration of a JP1 event.</p> <ul style="list-style-type: none"> <li>• A maximum of 100 reasons can be specified.</li> <li>• The permitted range is from -2,147,483,648 to 2,147,483,647.</li> </ul>                                                                         |

| No. | Item              | Attribute name | Comparison keyword                                                                                                                                                                  | Operand                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

<sup>#</sup>

If the integrated monitoring database and the IM Configuration Management database are enabled, and the comparison keyword is Match or Do not match, you can specify a business group name in a path format.

If the integrated monitoring database and the IM Configuration Management database are disabled, and a comparison keyword other than Match and Do not match is selected, a business group name specified in a path format is treated as a host name.

If the `-ignorecasehost` option of the `jcoimdef` command is set to ON, and a comparison keyword other than Regular expression is selected, the character string is no longer case sensitive.

### comparison-keyword

Specifies BEGIN (begins with), IN (matches), NOTIN (does not match), SUBSTR (includes), NOTSUBSTR (does not include), or REGEX (regular expression), TRANGE (time range), DEFINED (defined), or NOTDEFINED (not defined) as the comparison keyword. The comparison keyword is case sensitive.

To use the TRANGE (time range) comparison keyword, specify it as shown in the following table.

Table 2–60: Format for specifying TRANGE

| Comparison method        |                  | Format                                                | Specifiable range                                                               | Specification example                                                                                                    |

| Comparison method |               | Format                                           | Specifiable range                                                                   | Specification example                                                                                               |
|-------------------|---------------|--------------------------------------------------|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
|                   | xx days later | <i>base-time</i> Δ + <i>period</i><br>(days) DAY | <i>base-time</i> ≤ <i>attribute-value</i> ≤ <i>base-time</i> + <i>period</i> (days) | To specify the period from May 1, 2018, 00:00:00 to 180 days later than the base time:<br>20180501000000<br>+180DAY |

Legend:

Δ: A space

Specify the start date and time, the end date and time, and the base time in *YYYYMMDDhhmmss* format. The period (minutes, hours, and days) must be specified as a numeric value from 1 to 9,999. MIN, HOUR, and DAY are case sensitive.

An error results if you specify a period and the calculated date and time from the base time does not fall in an acceptable time range (from UTC 1970-01-01

00:00:00 to UTC 2099-12-31 23:59:59).

## Operand

Specifies a character string as the value to be compared with the attribute value specified by the comparison keyword. The operand is case sensitive.

If you specify two or more operands, separate them by one or more consecutive spaces or tabs. The OR condition is applied to the specified operands. Note that if a regular expression is specified, only one operand is allowed.

If you want to specify a space, a tab, an end-of-line code (CR or LF), or % as part of an operand, use the format shown in the table below. Note also that during maximum value checking for the definition format, each of these values is treated as a single character.

There is no limit on the maximum length of the operand. However, for Shift-JIS, the maximum number of event conditions (attribute name, comparison keyword, and operand) in *cnd* to *end-cnd* (event condition block) is 65,536 bytes.

| No. | Value to be specified | How to specify |
|-----|-----------------------|----------------|
| 1   | Tab (0x09)            | %09            |
| 2   | Space (0x20)          | %20            |
| 3   | % (0x25)              | %25            |
| 4   | Linefeed LF (0x0a)    | %0a            |
| 5   | Linefeed CR (0x0d)    | %0d            |

## Note:

- Relationship between the values of *date*, *rtime*, and *week*

When *date*, *rtime*, and *week* are set, the common exclusion-condition is enabled on every week day of *week* during a period of days specified in *date* from the start time to the end time specified in *rtime*.

When the end time of *rtime* indicates a time on the next day, the common exclusion-condition remains enabled until the end time on the next day.

For details about the applicable period, see 4.2.7 *Common exclusion-conditions* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## Example definition

When the following conditions exist, the example definition excludes events during the period from 2010/10/01 to 2010/10/31 on Mondays through Saturdays from 10:00 to 12:00:

- The event ID matches 1.
- The event level is Emergency or Alert.
- The registered host is specified with a regular expression as follows:
  - `host[0-9][0-9]`

```
DESC_VERSION=1
# comment
def common-exclusion-conditions-group-1
  cmt expiration: 2010/10/31
  id 1
  valid true
  date 20101001-20101031
  week 1,2,3,4,5,6
  rtime 1000-1200
  cnd
    B.ID IN 00000001
    E.SEVERITY IN Emergency Alert
    B.SOURCESERVER REGEX host[0-9][0-9]
  end-cnd
end-def
```

The definition example below excludes events from automated-action execution from 23:00 to next day 02:00 on every Monday through Saturday during the period between April 1, 2017 and May 1, 2017 when the following conditions are true:

- The event ID is 2.
- The severity is Emergency or Alert.
- The source host matches the following regular expression:
  - `host[0-9][0-9]`

```
DESC_VERSION=2
# comment
def common-exclusion-conditions-group-1
  cmt expiration: 2017/05/01
  id 1
  valid true
  ex-target action
  date 20170401-20170501
  week 1,2,3,4,5,6
  rtime 2300-0200
  cnd
    B.ID IN 00000002
    E.SEVERITY IN Emergency Alert
    B.SOURCESERVER REGEX host[0-9][0-9]
  end-cnd
end-def
```

## ◆ Common-exclusion-conditions display item definition file (common\_exclude\_filter\_attr\_list.conf)

### Format

```
# comment-line
attribute-name
attribute-name
attribute-name
.
.
.
attribute-name
```

### File

common\_exclude\_filter\_attr\_list.conf (common-exclusion-conditions display item definition file)

common\_exclude\_filter\_attr\_list.conf.model (model file for the common-exclusion-conditions display item definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\filter\attr\_list

For a logical host:

*shared-folder*\jplcons\conf\console\filter\attr\_list

In UNIX

For a physical host:

/etc/opt/jplcons/conf/console/filter/attr\_list

For a logical host:

*shared-directory*/jplcons/conf/console/filter/attr\_list

### Description

This definition file specifies the items that are to be displayed in the **Attribute name** display area of the Common Exclusion-Conditions Settings (Extended) window. The display items specified in the common-exclusion-conditions display item definition file are displayed in the **Attribute name** display area of the Common Exclusion-Conditions Settings (Extended) window in the order they are specified.

### When the definitions are applied

The definitions take effect when Central Console is started or when the definitions are reloaded by executing the jco\_spmc\_reload command.

### Information that is specified

#comment-line

A line beginning with a hash mark (#) is treated as a comment.

## attribute-name

The items to be displayed in the **Attribute name** display area of the Common Exclusion-Conditions Settings (Extended) window are specified in the common-exclusion-conditions display item definition file. Write one attribute name corresponding to a display item on each line. A maximum of 0 to 256 display items can be specified. The attribute name is case sensitive. Space and tab characters specified at the beginning or the end of the attribute name are ignored.

If you specify SEPARATOR, a horizontal line, such as -----, is displayed in the **Attribute name** display area of the Common Exclusion-Conditions Settings (Extended) window. You can use SEPARATOR to separate frequently used items from those used less frequently.

However, if you specify only SEPARATOR, only ----- is displayed in the **Attribute name** display area. If you then select -----, you will be unable to set the attribute name.

The following table lists the specifiable attribute names.

Table 2–61: List of display items

| No. | Display item                        | Attribute name           |
|-----|-------------------------------------|--------------------------|
| 1   | Event source host name <sup>#</sup> | E.JP1_SOURCEHOST         |
| 2   | Registered host name                | B.SOURCESERVER           |
| 3   | Event level                         | E.SEVERITY               |
| 4   | Object type                         | E.OBJECT_TYPE            |
| 5   | Object name                         | E.OBJECT_NAME            |
| 6   | Root object type                    | E.ROOT_OBJECT_TYPE       |
| 7   | Root object name                    | E.ROOT_OBJECT_NAME       |
| 8   | Occurrence                          | E.OCCURRENCE             |
| 9   | User name                           | E.USER_NAME              |
| 10  | Message                             | B.MESSAGE                |
| 11  | Product name                        | E.PRODUCT_NAME           |
| 12  | Event ID                            | B.ID                     |
| 13  | Start time                          | E.START_TIME             |
| 14  | End time                            | E.END_TIME               |
| 15  | Registered time                     | B.TIME                   |
| 16  | Arrived time                        | B.ARRIVEDTIME            |
| 17  | Extended attribute                  | OTHER_EXTENDED_ATTRIBUTE |
| 18  | Reason for registration             | B.REASON                 |
| 19  | Source process ID                   | B.PROCESSID              |
| 20  | Source user name                    | B.USERNAME               |
| 21  | Source user ID                      | B.USERID                 |
| 22  | Source group name                   | B.GROUPNAME              |
| 23  | Source group ID                     | B.GROUPID                |
| 24  | Source IP address                   | B.SOURCEIPADDR           |
| 25  | Object ID                           | E.OBJECT_ID              |

| No. | Display item | Attribute name |
|-----|--------------|----------------|
| 26  | Return code  | E.RESULT_CODE  |
| 27  | -----        | SEPARATOR      |

Note:

If the same attribute name is specified twice, both specifications are ignored.

Also, if the common-exclusion-conditions display item definition file cannot be read, and the number of valid display items is 0, items 1 to 26 are displayed.

#

If the event source host mapping function is not enabled, the item is not displayed in the Common Exclusion Condition Settings (Extended) window.

## ◆ Common-exclusion-conditions auto-input definition file (common\_exclude\_filter\_auto\_list.conf)

### Format

```
# comment
[DEFAULT_NAME common-exclusion-conditions-group-name]
attribute-name
attribute-name
.
.
attribute-name
attribute-name
```

### File

common\_exclude\_filter\_auto\_list.conf

common\_exclude\_filter\_auto\_list.conf.model (model file for the common-exclusion-conditions auto-input definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\filter\auto\_list

For a logical host:

*shared-folder*\jplcons\conf\console\filter\auto\_list

In UNIX

For a physical host:

/etc/opt/jplcons/conf/console/filter/auto\_list

For a logical host:

*shared-directory*/jplcons/conf/console/filter/auto\_list

## Description

This file defines the JP1 event attributes that are set automatically when the Common Exclusion-Conditions Settings (Extended) window opens. The window opens when a JP1 event is selected from the list of events in the Event Console window, and then **View - Exclude by Common Exclusion-Conditions** is chosen. You can also define a default name for the additional common exclusion conditions group.

## When the definitions are applied

The definitions take effect when Central Console is started or when the definitions are re-read by executing the `jco_spmc_reload` command.

## Information that is specified

`DEFAULT_NAME common-exclusion-conditions-group-name`

Specifies the identifier that defines the common exclusion conditions group name. The identifier must be on the first line in the file (the first line in the file that is not a null line or a comment line).

The common exclusion conditions group name specified for this parameter is displayed as the initial value when the Common Exclusion-Conditions Settings (Extended) window opens. The window opens when a JP1 event from the list of event in the Event Console window, and then **View - Exclude by Common Exclusion-Conditions** is chosen.

For the name, specify a character string with a maximum of 40 bytes. You can specify any character that is not a control character (0x00 to 0x1F, 0x7F to 0x9F). If a name with more than 40 bytes is specified, characters from the 41st are dropped, and the first 40 bytes of the character string are used as the common exclusion-conditions group name. If this parameter is omitted, `Add common exclusion conditions group` is assumed as the common exclusion-conditions group name.

*#comment-line*

A line beginning with a hash mark (#) is treated as a comment.

*attribute-name*

For the common-exclusion-conditions auto-input definition file, specify the attribute of a JP1 event that is to be set as an event condition when the Common Exclusion-Conditions Settings (Extended) window opens. The Common Exclusion-Conditions Settings (Extended) window opens when a JP1 event from the list of JP1 events in the Event Console window is selected, and then **View - Exclude by Common Exclusion-Conditions** is chosen. The condition for the attribute name specified for this parameter is displayed as the initial value when the Common Exclusion-Conditions Settings (Extended) window opens. The window opens when a JP1 event from the list of JP1 events in the Event Console window is selected, and then **View - Exclude by Common Exclusion-Conditions** is chosen.

For the definition items, write on each line one attribute name of a JP1 event that will be set.

The attribute name is case sensitive. Any space or tab character at the beginning or at the end of the attribute name is ignored.

If the same attribute name is specified twice, it is ignored, and the `KAVB1160-W` message is output to the integrated trace log file.

The order of JP1 events to be displayed automatically in the **Event conditions** section of the Common Exclusion-Conditions Settings (Extended) window is determined by the order in which the attributes are written in the common-exclusion-conditions display item definition file (`common_exclude_filter_attr_list.conf`).

The following table lists the attribute names that can be specified.

Table 2–62: List of display items

| No. | Display item           | Attribute name   |
|-----|------------------------|------------------|
| 1   | Event source host name | E.JP1_SOURCEHOST |

| No. | Display item            | Attribute name     |
|-----|-------------------------|--------------------|
| 2   | Registered host name    | B.SOURCESERVER     |
| 3   | Event level             | E.SEVERITY         |
| 4   | Object type             | E.OBJECT_TYPE      |
| 5   | Object name             | E.OBJECT_NAME      |
| 6   | Root object type        | E.ROOT_OBJECT_TYPE |
| 7   | Root object name        | E.ROOT_OBJECT_NAME |
| 8   | Occurrence              | E.OCCURRENCE       |
| 9   | User name               | E.USER_NAME        |
| 10  | Message                 | B.MESSAGE          |
| 11  | Product name            | E.PRODUCT_NAME     |
| 12  | Event ID                | B.ID               |
| 13  | Reason for registration | B.REASON           |
| 14  | Source process ID       | B.PROCESSID        |
| 15  | Source user name        | B.USERNAME         |
| 16  | Source user ID          | B.USERID           |
| 17  | Source group name       | B.GROUPNAME        |
| 18  | Source group ID         | B.GROUPID          |
| 19  | Source IP address       | B.SOURCEIPADDR     |
| 20  | Object ID               | E.OBJECT_ID        |
| 21  | Return code             | E.RESULT_CODE      |

Note:

If the same attribute name is specified twice, both specifications are ignored.

Also, if the common-exclusion-conditions auto-input definition file cannot be read, and the number of valid display items is 0, items 1 to 3 and items 10 to 12 are displayed.

## ◆ Display item definition file for the repeated event condition (event\_storm\_attr\_list.conf)

### Format

```
# comment
attribute-name
attribute-name
.
attribute-name
```

### File

event\_storm\_attr\_list.conf (Display item definition file for the repeated event condition)

event\_storm\_attr\_list.conf.model (model file for the display item definition file for the repeated event condition)

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\event\_storm\attr\_list

For a logical host:

*shared-folder*\jplcons\conf\console\event\_storm\attr\_list

In UNIX

For a physical host:

/etc/opt/jplcons/conf/console/event\_storm/attr\_list

For a logical host:

*shared-directory*/jplcons/conf/console/event\_storm/attr\_list

## Description

Specifies the items to be displayed in the **Attribute name** display area of the Repeated Event Condition Settings window. The items are displayed in this area in the order in which they are specified in the file.

## When the definitions are applied

The contents of the definition file take effect when Central Console is started and when the definitions are read again by executing the `jco_spmc_reload` command.

## Information that is specified

*#comment-line*

A line beginning with a hash mark (#) is treated as a comment.

*attribute-name*

In the display item definition file for the repeated event condition, specify an item to be displayed in the **Attribute name** display area of the Repeated Event Condition Settings window. Specify the attribute names of the items you want to be displayed by specifying one item per line. You can specify from 0 to 256 items.

An attribute name is case sensitive. Any space or tab characters immediately preceding or following the attribute name will be ignored.

If you specify SEPARATOR, a horizontal line like ----- is displayed in the **Attribute name** display area of the Repeated Event Condition Settings window. You can use SEPARATOR to separate items used frequently from those used infrequently.

However, if you specify only SEPARATOR, only ----- is displayed in the **Attribute name** display area. If you then select -----, you will be unable to set the attribute name.

The following table lists the attribute names that can be specified.

Table 2–63: List of display items

| No. | Display item                        | Attribute name   |
|-----|-------------------------------------|------------------|
| 1   | Event source host name <sup>#</sup> | E.JP1_SOURCEHOST |
| 2   | Registered host name                | B.SOURCESERVER   |

| No. | Display item                        | Attribute name           |
|-----|-------------------------------------|--------------------------|
| 3   | Event level                         | E.SEVERITY               |
| 4   | Object type                         | E.OBJECT_TYPE            |
| 5   | Object name                         | E.OBJECT_NAME            |
| 6   | Root object type                    | E.ROOT_OBJECT_TYPE       |
| 7   | Root object name                    | E.ROOT_OBJECT_NAME       |
| 8   | Occurrence                          | E.OCCURRENCE             |
| 9   | User name                           | E.USER_NAME              |
| 10  | Message                             | B.MESSAGE                |
| 11  | Product name                        | E.PRODUCT_NAME           |
| 12  | Event ID                            | B.ID                     |
| 13  | Start time                          | E.START_TIME             |
| 14  | End time                            | E.END_TIME               |
| 15  | Registered time                     | B.TIME                   |
| 16  | Arrived time                        | B.ARRIVEDTIME            |
| 17  | Program-specific extended attribute | OTHER_EXTENDED_ATTRIBUTE |
| 18  | Reason for registration             | B.REASON                 |
| 19  | Source process ID                   | B.PROCESSID              |
| 20  | Source user name                    | B.USERNAME               |
| 21  | Source user ID                      | B.USERID                 |
| 22  | Source group name                   | B.GROUPNAME              |
| 23  | Source group ID                     | B.GROUPID                |
| 24  | Source IP address                   | B.SOURCEIPADDR           |
| 25  | Object ID                           | E.OBJECT_ID              |
| 26  | Result code                         | E.RESULT_CODE            |
| 27  | -----                               | SEPARATOR                |

Note:

If an attribute name is specified twice, both specifications are ignored.

Also, if the display item definition file for the repeated event condition cannot be read, and the number of valid display items is 0, items 1 to 26 are displayed.

#

If the user mapping function of the event source host is not enabled, this item is not displayed in the Repeated Event Condition Settings window.

## ◆ Auto-input definition file for the repeated event condition (event\_storm\_auto\_list.conf)

### Format

```
# comment
[DEFAULT_NAME repeated-event-condition-name]
attribute-name
attribute-name
.
.
attribute-name
attribute-name
```

### File

event\_storm\_auto\_list.conf

event\_storm\_auto\_list.conf.model (model file for the auto-input definition file for the repeated event condition)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\event\_storm\auto\_list

For a logical host:

*shared-folder*\jplcons\conf\console\event\_storm\auto\_list

In UNIX

For a physical host:

/etc/opt/jplcons/conf/console/event\_storm/auto\_list

For a logical host:

*shared-directory*/jplcons/conf/console/event\_storm/auto\_list

### Description

This file defines the JP1 event attributes that are set automatically when the Repeated Event Condition Settings window opens. The window opens when the user selects a JP1 event from the list of events in the Event Console window and then chooses **Display - Suppress by Repeated Event Conditions**. You can also define a default name for the repeated event condition.

### When the definitions are applied

The contents of the definition file take effect when Central Console is started and when the definitions are re-loaded by executing the `jco_spmc_reload` command.

## Information that is specified

DEFAULT\_NAME *repeated-event-condition-name*

Indicates the identifier that defines the repeated event condition name. The identifier must be on the first line in the file (more specifically, the first line in the file that is not a null line or a comment line).

The common exclusion conditions group name specified for this parameter is displayed as the initial value when the Repeated Event Condition Settings window opens. The window opens when the user selects a JP1 event from the list of events in the Event Console window and then chooses **Display - Suppress by Repeated Event Conditions**.

For the name, you can specify a character string that does not exceed 40 bytes. You can specify any character that is not a control character (0x00 to 0x1F, 0x7F to 0x9F). If a name with more than 40 bytes is specified, characters from the 41st are dropped, and the first 40 bytes of the character string are used as the repeated event condition name. If this parameter is omitted, *additional-repetition-event-condition* is assumed as the repeated event condition name.

*#comment-line*

A line beginning with a hash mark (#) is treated as a comment.

*attribute-name*

In the auto-input definition file for the repeated event condition, specify a JP1 event attribute to be set as an event condition when the Repeated Event Condition Settings window opens. The window opens when the user selects a JP1 event from the list of events in the Event Console window, and then chooses **Display - Suppress by Repeated Event Conditions**. The condition of the attribute name specified for this parameter is displayed as the initial value when the Repeated Event Condition Settings window opens. The window opens when the user selects a JP1 event from the list of events in the Event Console window, and then chooses **Display - Suppress by Repeated Event Conditions**. Specify the attribute names of items that are to be set as definition items by specifying one item per line.

An attribute name is case sensitive. Any space or tab characters immediately preceding or following the attribute name will be ignored.

If the same attribute is specified twice, both specifications are ignored, and the KAVB1896-W message is output to the integrated trace log file.

The order of JP1 events that are displayed automatically in the **Event conditions** section of the Repeated Event Condition Settings window is determined by the order in which the attribute names are written in the display item definition file for the repeated event condition (*event\_storm\_attr\_list.conf*).

The following table lists the attribute names that can be specified.

Table 2–64: List of display items

| No. | Display item           | Attribute name     |
|-----|------------------------|--------------------|
| 1   | Event source host name | E.JP1_SOURCEHOST   |
| 2   | Registered host name   | B.SOURCESERVER     |
| 3   | Event level            | E.SEVERITY         |
| 4   | Object type            | E.OBJECT_TYPE      |
| 5   | Object name            | E.OBJECT_NAME      |
| 6   | Root object type       | E.ROOT_OBJECT_TYPE |
| 7   | Root object name       | E.ROOT_OBJECT_NAME |
| 8   | Occurrence             | E.OCCURRENCE       |
| 9   | User name              | E.USER_NAME        |
| 10  | Message                | B.MESSAGE          |
| 11  | Product name           | E.PRODUCT_NAME     |

| No. | Display item            | Attribute name |
|-----|-------------------------|----------------|
| 12  | Event ID                | B.ID           |
| 13  | Reason for registration | B.REASON       |
| 14  | Source process ID       | B.PROCESSID    |
| 15  | Source user name        | B.USERNAME     |
| 16  | Source user ID          | B.USERID       |
| 17  | Source group name       | B.GROUPNAME    |
| 18  | Source group ID         | B.GROUPID      |
| 19  | Source IP address       | B.SOURCEIPADDR |
| 20  | Object ID               | E.OBJECT_ID    |
| 21  | Result code             | E.RESULT_CODE  |

Note:

If the same attribute name is specified twice, both specifications are ignored.

Also, if the auto-input definition file for the repeated event condition cannot be read, and the number of valid display items is 0, items 1 to 3 and items 10 to 12 are displayed.

## ◆ Display item definition file for the severity change definition (chsev\_attr\_list.conf)

### Format

```
# comment-line
attribute-name
attribute-name
.
.
attribute-name
```

### File

chsev\_attr\_list.conf (display item definition file for the severity change definition)

chsev\_attr\_list.conf.model (model file of the display item definition file for the severity change definition)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\chsev\attr\_list

For a logical host:

*shared-folder*\jplcons\conf\chsev\attr\_list

## In UNIX

For a physical host:

`/etc/opt/jplcons/conf/chsev/attr_list`

For a logical host:

`shared-directory/jplcons/conf/chsev/attr_list`

## Description

This definition file specifies the items to display in the Attribute name display area of the Severity Change Definition Settings window. The display items specified in the display item definition file for the severity change definition are displayed in the Attribute name display area of the Severity Change Definition Settings window in the specified order.

## When the definitions are applied

The contents of the definition file take effect when Central Console is started, and the definition is reloaded by executing the `jco_spmc_reload` command.

## Information that is specified

### *#comment-line*

A line beginning with a hash mark (#) is treated as a comment.

### *attribute-name*

For the display item definition file for the severity change definition, specify the display items to display in the **Attribute name** display area of the Severity Change Definition Settings window. Write an attribute name corresponding to the display item per line. You can specify 0 to 256 display items.

The attribute name is case sensitive. Single-byte spaces and tabs before or after the attribute name are ignored.

If you specify `SEPARATOR`, `-----` is displayed in the **Attribute name** display area of the Severity Change Definition Settings window. You can set `SEPARATOR` to separate frequently used items from those used less frequently.

However, if you specify only `SEPARATOR`, only `-----` is displayed in the **Attribute name** display area. In this case, if you select `-----`, you cannot set the attribute name.

The following table lists the specifiable attribute names.

Table 2–65: List of display items

| No. | Display item                        | Attribute name     |
|-----|-------------------------------------|--------------------|
| 1   | Event source host name <sup>#</sup> | E.JP1_SOURCEHOST   |
| 2   | Registered host name                | B.SOURCESERVER     |
| 3   | Event level                         | E.SEVERITY         |
| 4   | Object type                         | E.OBJECT_TYPE      |
| 5   | Object name                         | E.OBJECT_NAME      |
| 6   | Root object type                    | E.ROOT_OBJECT_TYPE |
| 7   | Root object name                    | E.ROOT_OBJECT_NAME |
| 8   | Occurrence                          | E.OCCURRENCE       |
| 9   | User name                           | E.USER_NAME        |
| 10  | Message                             | B.MESSAGE          |

| No. | Display item                        | Attribute name           |
|-----|-------------------------------------|--------------------------|
| 11  | Product name                        | E.PRODUCT_NAME           |
| 12  | Event ID                            | B.ID                     |
| 13  | Destination event server name       | B.DESTSERVER             |
| 14  | Program-specific extended attribute | OTHER_EXTENDED_ATTRIBUTE |
| 15  | Reason for registration             | B.REASON                 |
| 16  | Source process ID                   | B.PROCESSID              |
| 17  | Source user name                    | B.USERNAME               |
| 18  | Source user ID                      | B.USERID                 |
| 19  | Source group name                   | B.GROUPNAME              |
| 20  | Source group ID                     | B.GROUPID                |
| 21  | Object ID                           | E.OBJECT_ID              |
| 22  | Result code                         | E.RESULT_CODE            |
| 23  | -----                               | SEPARATOR                |

Note:

If the same attribute name is specified twice, both specifications are ignored.

Also, if the display item definition file for the severity change definition cannot be read, and the number of valid display items is 0, items 1 to 22 are displayed.

#

If the mapping function of the source host is not enabled, the event source host name is not displayed in the Severity Change Definition Settings window.

## ◆ Auto-input definition file for the severity change definition (chsev\_auto\_list.conf)

### Format

```
# comment-line
[DEFAULT_NAME severity-changing-definition-name]
attribute-name
attribute-name
.
.
attribute-name
attribute-name
```

### File

chsev\_auto\_list.conf

chsev\_auto\_list.conf.model (model file of the auto-input definition file for the severity change definition)

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\chsev\auto\_list

For a logical host:

*shared-folder*\jplcons\conf\chsev\auto\_list

In UNIX

For a physical host:

/etc/opt/jplcons/conf/chsev/auto\_list

For a logical host:

*shared-directory*/jplcons/conf/chsev/auto\_list

## Description

This file defines the JP1 event attribute that is set automatically when you select a JP1 event in the event list of the Event Console window, select **View**, and then **Add Severity Change Definition Settings** to open the Add Severity Change Definition Settings window. Also, the default severity changing definition name can be defined.

## When the definitions are applied

The contents of the definition file take effect when Central Console starts, and when the definition is reloaded by executing the `jco_spmd_reload` command.

## Information that is specified

# *comment-line*

A line beginning with a hash mark (#) is treated as a comment.

DEFAULT\_NAME *severity-changing-definition-name*

Indicates the identifier that defines the severity changing definition name. The identifier must be written at the beginning of the file excluding the comment and blank lines.

The severity changing definition name specified for this parameter is displayed as the initial value when you select a JP1 event from the event list in the Event Console window, select **View**, and then **Add Severity Change Definition Settings** to open the Add Severity Change Definition Settings window.

Specify a character string of maximum of 40 bytes. Any characters, other than control characters (0x00 to 0x1F, and 0x7F to 0x9F), are permitted. If you specify over 40 bytes of characters, the characters from the 41st byte are dropped, and the first 40 bytes are treated as the severity changing definition name. If you omit this parameter, *additional-severity-changing-definition* is used as the *severity-changing-definition-name*.

*attribute-name*

For the auto-input definition file for the severity change definition, specify the JP1 event attribute which is set as an event condition when you select a JP1 event from the event list in the Event Console window, select **View**, and then **Add Severity Change Definition Settings** to open the Add Severity Change Definition Settings window. The attribute name condition specified for this parameter is displayed as the initial value when you select a JP1 event from the event list in the Event Console window, select **View**, and then **Add Severity Change Definition Settings** to open the Add Severity Change Definition Settings window.

For the definition item, specify one attribute name of the JP1 event to be set for each line.

The attribute name is case sensitive. Single-byte spaces or tabs before or after the attribute name are ignored.

Note that if you specify the same attribute name more than once, both values are ignored, and the KAVB1935-W message is output to the integrated trace log file.

JP1 event attributes are displayed automatically in the **Event conditions** section of the Severity Change Definition Settings window in the order they were written in the display item definition file for the severity change definition (`chsev_attr_list.conf`).

The following table lists the specifiable attribute names.

**Table 2–66: List of display items**

| No. | Display item                        | Attribute name     |
|-----|-------------------------------------|--------------------|
| 1   | Event source host name <sup>#</sup> | E.JP1_SOURCEHOST   |
| 2   | Registered host name                | B.SOURCESERVER     |
| 3   | Event level                         | E.SEVERITY         |
| 4   | Object type                         | E.OBJECT_TYPE      |
| 5   | Object name                         | E.OBJECT_NAME      |
| 6   | Root object type                    | E.ROOT_OBJECT_TYPE |
| 7   | Root object name                    | E.ROOT_OBJECT_NAME |
| 8   | Occurrence                          | E.OCCURRENCE       |
| 9   | User name                           | E.USER_NAME        |
| 10  | Message                             | B.MESSAGE          |
| 11  | Product name                        | E.PRODUCT_NAME     |
| 12  | Event ID                            | B.ID               |
| 13  | Destination event server name       | B.DESTSERVER       |
| 14  | Reason for registration             | B.REASON           |
| 15  | Source process ID                   | B.PROCESSID        |
| 16  | Source user name                    | B.USERNAME         |
| 17  | Source user ID                      | B.USERID           |
| 18  | Source group name                   | B.GROUPNAME        |
| 19  | Source group ID                     | B.GROUPID          |
| 20  | Object ID                           | E.OBJECT_ID        |
| 21  | Result code                         | E.RESULT_CODE      |

Note:

If the same attribute name is specified twice, both specifications are ignored.

Also, if the auto-input definition file for the severity change definition cannot be read, and the number of valid display items is 0, items 1 to 3, and items 10 to 12 are displayed.

<sup>#</sup>

If the mapping function of the source host is not enabled, the event source host name is not displayed in the Add Severity Change Definition Settings window.

## ◆ Definition file for opening monitor windows

### Format

```
[@encode character-encoding]
DESC_VERSION=0300
{key-definition(SUBKEY parameter is used)
subkey-definition
association-definition
|key-definition(INTERFACE parameter is used)}
call-interface-definition
```

### File

*hitachi\_xxxx\_mon.conf*

(definition file for opening monitor windows for a linked product)

*company-name\_product-name\_mon.conf*

(user-defined definition file for opening monitor windows)

*company-name\_series-name\_product-name\_mon.conf*

(user-defined definition file for opening monitor windows)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\console\monitor\

For a logical host:

*shared-folder*\jplcons\conf\console\monitor\

In UNIX

For a physical host:

*/etc/opt/jplcons/conf/console/monitor/*

For a logical host:

*shared-directory/jplcons/conf/console/monitor/*

### Description

This definition file is used to define settings for calling monitor windows (such as a monitor window at an event source) from the Integrated Operation Viewer window of Intelligent Integrated Management Base, or the Event Console window of Central Console. Use this file to create a key from information such as the event ID and attributes, and a command line parameter from the event attributes.

The encoding defined in the definition file for calling monitor windows must be UTF-8 for JP1/IM - Manager for Linux and Shift-JIS or EUCJIS for JP1/IM - Manager for an OS other than Linux. Because, hitachi is used for the default file name, use a name other than *hitachi* for *company-name*.

If *hitachi* is specified for the company name in a definition file for opening monitor windows, this definition file contains system standard definition information, and therefore a user cannot create, change, or delete the file.

JP1/IM provides the `jcomonitorfcheck` command for checking the contents of the definition file for opening monitor windows. For details about this command, see *jcomonitorfcheck* in *Chapter 1. Commands*.

## When the definitions are applied

The definition takes effect after JP1/IM - Manager is restarted or when the `jco_spmc_reload` command is executed. Note that the changes made to the definition while the user is logged in to JP1/IM - View or the Intelligent Integrated Management Base, are not applied. You need to restart JP1/IM - View or the Intelligent Integrated Management Base to apply the change.

## Information that is specified

### @encode

Specifies the character encoding that is to be used in the definition file for opening monitor windows. This item is optional.

To create an additional file for definition file for opening monitor windows, use an `@encode` statement to specify the character set for the definition file.

Item names will be expressed in characters that can be represented in the character encoding specified in the `@encode` statement. In addition, the definition file for opening monitor windows will be saved in the character encoding specified in the `@encode` statement.

In the following circumstances, item names displayed in JP1/IM - View or the Integrated Operation Viewer window, might be garbled:

- If the item name uses characters that cannot be represented in the character encoding specified in the `@encode` statement
- If the character encoding specified in the `@encode` statement does not match the character encoding in which the file was saved

If no `@encode` statement exists or if there is an error in the specified character set name that follows the `@encode` statement, the character set is determined automatically. However, depending on the contents of the definition file, the character encoding might not be determined correctly.

The specifiable character encodings are as follows:

- C
- EUCJIS
- SJIS
- UTF-8
- GB18030

### Note

If you use UTF-8 as the encoding to save a definition file, save the file without attaching a BOM (byte order mark).

An error is output in the following cases:

- A character encoding other than C, EUCJIS, SJIS UTF-8 or GB18030 is specified
- The definition file does not begin with `@encode`.
- `@encode` is not followed by a character encoding specification.

## Note

If you use a definition file for extended event attributes provided by another product, make sure the character encoding specified in the `@encode` statement matches the character encoding used in the definition file. In addition, if you will be transferring definition files, do not convert the character encoding of the definition files.

DESC\_VERSION=0300

This is the table version record.

## key-definition

Defines a fixed key in the event attributes that is to be used when a monitor window is opened. The key consists of three items:

- Event ID
- Product name
- Version

The combination of these attributes defines a link to operations and subkeys.

## Format

```
DEF_KEY PRODUCT_NAME="product-name"
EVENT_ID=event-ID
[VERSION=version | ALL]
{ SUBKEY=subkey
  | INTERFACE=interface-name }
```

## Arguments

- PRODUCT\_NAME="*product-name*"

Specifies a product name as a character string, such as `/HITACHI/JP1/AJS`. This value must be the same as a value that is set in a `PRODUCT_NAME` extended attribute.

- EVENT\_ID=*event-ID*

Specifies only the base part of an event identifier, expressed as eight hexadecimal characters. The extended part is ignored. If you need to include the extended part set for a JP1/SES event, use a subkey.

- VERSION=*version*

Specifies a version. The version specified in this argument is compared with the `ACTION_VERSION JP1` event extended attribute. The version can be expressed in numeric characters (from 0 to 9), alphabetic characters (A to Z), the forward slash (/), and the hyphen (-). The alphabetic characters are not case sensitive.

Specify a single version as a string of no more than 8 bytes. To specify a range of versions, separate the start version from the end version with a hyphen (-). In this case, there must be at least one space preceding and following the hyphen.

The version specified here cannot duplicate any version specified in any other key definition.

- SUBKEY=*subkey*

Specifies the name of a subkey. This parameter and the `INTERFACE` parameter are mutually exclusive.

If you specify the `SUBKEY` parameter, you need the subkey definition corresponding to the subkey name specified for `SUBKEY`, and the association definition.

- INTERFACE=*interface-name*

Specifies an interface name. For the key to define, specify only one interface that is to be used when the monitor window opens. This parameter and the `SUBKEY` parameter are mutually exclusive.

If you specify the `INTERFACE` parameter, you cannot use the subkey definition and association definition.

## Notes:

The versions are compared in ascending order. If the start version is greater than the end version, that key definition is ignored even though no error is issued.

The value specified in `PRODUCT_NAME` must be the same as the value specified in a `PRODUCT_NAME JP1` event extended attribute.

## subkey-definition

When the monitor window is opened, the subkey definition is linked from the fixed key and registers the event attributes as the key.

### Format

`DEF_SUBKEY`

`NAME=subkey-name`

`KEYS=attribute-name-1 [ , attribute-name-2 [ , attribute-name-3 [ , attribute-name-4 ] ] ]`

### Arguments

- `NAME=subkey-name`

Specifies a name for the subkey, expressed using from 1 to 16 alphanumeric characters; no spaces or control characters can be used. This name is not case sensitive.

- `KEYS=attribute-name-1 [ , attribute-name-2 [ , attribute-name-3 [ , attribute-name-4 ] ] ]`

Specifies attribute names. The following table shows the specification formats of the attribute names.

**Table 2–67: Specification formats of the attribute names**

| Specification format           | Value format                      | Description                                                             |
|--------------------------------|-----------------------------------|-------------------------------------------------------------------------|
| <code>B.ARRIVEDTIME</code>     | 13-digit decimal character string | Arrived time (time in milliseconds since UTC 1970-01-01 at 00:00:00)    |
| <code>B.DESTSERVER</code>      | Character string                  | Target event server name                                                |
| <code>B.GROUPNAME</code>       | Character string                  | Source group name                                                       |
| <code>B.IDBASE</code>          | 8 hexadecimal characters          | Base part of the event ID                                               |
| <code>B.IDEXT</code>           | 8 hexadecimal characters          | Extended part of the event ID                                           |
| <code>B.PROCESSID</code>       | Decimal character string          | Source process ID                                                       |
| <code>B.SEQNO</code>           | Decimal character string          | Sequence number in the database                                         |
| <code>B.SOURCESEQNO</code>     | Decimal character string          | Sequence number by source                                               |
| <code>B.SOURCESERVER</code>    | Character string                  | Event-issuing server name                                               |
| <code>B.TIME</code>            | 13-digit decimal character string | Registered time (time in milliseconds since UTC 1970-01-01 at 00:00:00) |
| <code>B.USERNAME</code>        | Character string                  | Source user name                                                        |
| <code>B.MESSAGE</code>         | Character string                  | Message                                                                 |
| <code>E.JP1_SOURCEHOST#</code> | Character string                  | Event source host name                                                  |
| <code>E.xxxxxxx</code>         | Character string                  | Extended attribute                                                      |

#

A business group name cannot be used for the event-issuing server name (`B.SOURCESERVER`) and the event source host name (`E.JP1_SOURCEHOST`). If a business group name is specified, it is treated as a host name.

## association-definition

Defines the association between subkey values and the interface.

## Format

```
DEF_IF_RELATION
SUBKEY_NAME=subkey-name
{ VALUE1="attribute-value-1" [ [ VALUE2="attribute-value-2" ] . . . ]
| KEY_DEFAULT }
IF_NAME=interface-name
```

## Arguments

- SUBKEY\_NAME=*subkey-name*

Specifies the name of the subkey. Express the name using from 1 to 16 alphanumeric characters; no spaces or control characters can be used. This name is not case sensitive.

- VALUE*n*="*attribute-value*"

Specifies an attribute value and its sort order. Specify for *n* an integer in the range from 1 to 4 representing the sort order among the attributes specified in the KEYS parameter in the subkey definition. The key values must match exactly. A regular expression cannot be used for the value. For a list of the specifiable attributes and their specification formats, see the explanation of *subkey-definition*.

If any of the attributes, such as VALUE1, VALUE2, . . . , does not match, the interface specified in KEY\_DEFAULT is used for the corresponding JP1 event.

- KEY\_DEFAULT

Specify this argument instead of VALUE1, VALUE2, . . . , in order to create an association with the interface when there is not an exact match with the values specified in VALUE1, VALUE2, . . . .

- IF\_NAME=*interface-name*

Specifies the name of the interface that is to be called when the subkey values match. Express the interface name using from 1 to 16 alphanumeric characters; no spaces or control characters can be used. This name is not case sensitive.

## *call-interface-definition*

Defines the interface to be used when a monitor window is opened.

## Format

```
DEF_MTR_CALL
NAME=interface-name
EXEC_ID=application-execution-definition-identifier
PATH="command-arguments"
[ PARAM=attribute-name-1 [ , attribute-name-2 . . . ] ]
```

## Arguments

- NAME=*interface-name*

Specifies a name for the interface. Express the name using from 1 to 16 alphanumeric characters; no spaces or control characters can be used. This name is not case sensitive.

- EXEC\_ID=*application-execution-definition-identifier*

Specifies the identifier for an application execution definition. You must specify an identifier defined in the definition file for executing applications on the viewer.

You can launch the default browser by specifying "default\_browser" for the EXEC\_ID parameter. If you specify "default\_browser" for the EXEC\_ID parameter, specify a URL for the PATH parameter.

Note that a character string beginning with jco\_ cannot be used because it is reserved as the application execution definition identifier.

- PATH="*command-arguments*"

Specifies command arguments that are to be passed to the executable file specified in EXEC\_ID. The command line is formed by the name of the executable file specified in EXEC\_ID and the arguments specified here. For example, you would specify arg1 and arg2 in the PATH parameter to form the following command line:

```
"app.exe arg1 arg2"
```

You can also specify in the PATH parameter reserved keywords that will be replaced with values from the viewer's operating environment attributes and event attributes. The following lists and describes the specifiable substitute keywords.

Table 2–68: Specifiable substitute keywords

| Keyword              | Substituted value                                                                          |
|----------------------|--------------------------------------------------------------------------------------------|
| %JCO_JP1USER%        | Central Console or the Intelligent Integrated Management Base are login user name          |
| %JCO_INSTALL_PATH%#  | Name of the viewer installation folder                                                     |
| %IM_EVC_PARAMETER_n% | Event attribute value specified in PARAM<br>(n: integer of 1 or greater)                   |
| %IM_EVC_LANGUAGE%    | Depending on the language environment, the language switches between Japanese and English. |

#: In the Intelligent Integrated Management Base, the string is not substituted.

• PARAM=*attribute-name-1* [ , *attribute-name-2* . . . ]

Specifies the names of event attributes whose values are to be set. Sequential numbers that begin with 1 are assigned to the attribute names. This sequence corresponds to *n* in the substitute keywords.

Separate multiple event attributes with the comma, as shown in the example below:

```
B.EXTID, E.A0
```

You can specify some of the basic attributes and extended attributes. For details about the specifiable attributes and their specification formats, see the explanation of *subkey-definition*.

## Example definition

This example opens a monitor window from the JP1 event that traps the Windows event log:

Note:

In this example, a line number is assigned at the beginning of each line for explanatory purposes.

```
1 DESC_VERSION=0300
2 #/HITACHI/JP1/NTEVENT_LOGTRAP 0600 TO
3 # Operating version
4 # 0600 FROM NT VERSION JP1/NTEVENT_LOGTRAP 0600 TO
5 DEF_KEY PRODUCT_NAME="/HITACHI/JP1/NTEVENT_LOGTRAP/NETMDM" EVENT_ID=00003A71 SUBKEY=SAMPLE
6 DEF_SUBKEY NAME=SAMPLE KEYS=E.A5
7 DEF_IF_RELATION SUBKEY_NAME=SAMPLE VALUE1="8010" IF_NAME=NETM_DM
8 DEF_MIR_CALL NAME=NETM_DM EXEC_ID=HITACHI_NETM_DM PATH="netmdm_argument"
```

Line 1

Indicates the character encoding used for the definition file. In this example, the character encoding is UTF-8.

Line 2

DESC\_VERSION=0300 means that the description format version of this file is 0300.

Lines 3 to 5

These are comment lines. We recommend that you include the scope of the operating version.

Line 6

This is a key definition record. It means that if the product name is /HITACHI/JP1/NTEVENT\_LOGTRAP and the event ID is 00003A71, then the subkey SAMPLE is used to determine which monitor window is opened.

Line 7

This is a subkey definition record. It declares that the extended attributes `PRODUCT_NAME` and `A5` (Windows event log ID) are used with the subkey name `SAMPLE`.

Line 8

This is an association definition record. It means that if the value of subkey `E.A5` matches `8010`, the interface `NETM_DM` is used to display the monitor window.

Line 9

This is a call interface definition record. It means that the interface name is `NETM_DM` and the argument `netmdm_argument` is passed to the command whose application execution definition identifier is `HITACHI_NETM_DM`, which is then executed.

## ◆ Email environment definition file (jimmail.conf)

### Format

```
Charset=email-character-encoding
From=sender-email-address
DefaultTo=default-destination-email-address[,default-destination-email-address...]
SmtpServer=SMTP-server-name
SmtpPort=SMTP-port-number
AuthMethod=authentication-method-when-sending-email
SmtpAuthPort=SMTP-AUTH-authentication-submission-port-number
Pop3Server=POP3-server-name
Pop3Port=POP3-port-number
AuthUser=authentication-account-name
AuthPassword=authentication-password
ConnectTimeout=network-connection-timeout-period
SoTimeout=communication-timeout-period
MailSubjectCutting=email-subject-drop-setting
MailNewLine=email-linefeed-code
```

### File

`jimmail.conf` (email environment definition file)

`jimmail.conf.model` (model file of the email environment definition file)

### Storage directory

In Windows

For a physical host:

*Console-path*\conf\mail

For a logical host:

*shared-folder*\JP1Cons\conf\mail

## Description

The email environment definition file is a definition file that sets information required to send an email, including email server host names, authentication methods, authentication account names, and passwords.

## When the definitions are applied

The definition takes effect when the `jimmail` command is executed.

## Information that is specified

The following rules are applied to the email environment definition file:

- Each entry must be specified on a line in *parameter-name=setting-value* format. On each line, *parameter-name* and *setting-value* are separated by the first equal sign (0x3d).
- Only CR (0x0d) + LF (0x0a) is treated as a line break. If line break codes other than CRLF are contained, the line break codes are converted to CRLF before output when a password is set by using the `jimmailpasswd` command.
- The parameter name is case sensitive.
- A line beginning with # (0x23) or Δ# is a comment statement. However, if there is a character other than a single-byte space (0x20) or a tab (0x09) before #, the line is not treated as a comment statement (Δ indicates a single-byte space or a tab).
- Single-byte spaces or tabs are treated as follows (Δ indicates a single-byte space or a tab):
  - Single-byte spaces or tabs immediately before or after a parameter name are ignored.  
Example: Δ*parameter-name*Δ=*setting-value*
  - Single-byte spaces or tabs immediately before or after the setting value are ignored. However, they are treated as characters and not ignored for the `AuthPassword` parameter.  
Example: *parameter-name*=Δ*setting-value*Δ
- If an invalid parameter is written, an error occurs. Also, if there is no equal sign (=) after a parameter name, an error occurs.

`Charset=email-character-encoding`

Defines the character encoding for the subject and text of an email to send.

The character encoding is not case sensitive.

The following table lists the initial values for the `Charset` parameter, and a value to be set if the value for the `Charset` parameter is not obtained.

**Table 2–69: Initial values for the Charset parameter and setting values when the value could not be obtained**

| Environment              | Initial value | Setting value when the value could not be obtained |
|--------------------------|---------------|----------------------------------------------------|
| Japanese environment     | iso-2022-jp   | iso-8859-1                                         |
| Non-Japanese environment | iso-8859-1    | iso-8859-1                                         |

The following table lists the character encoding that can be specified for `Charset`.

If you specify character encoding that cannot be specified, the setting value in the above table is assumed.

Table 2–70: Character encoding that can be specified for Charset

| Character encoding | Description                       |
|--------------------|-----------------------------------|
| iso-2022-jp        | JIS encoding                      |
| shift_jis          | Shift-JIS encoding                |
| euc-jp             | EUC encoding                      |
| utf-8              | UTF-8 encoding                    |
| iso-8859-1         | Latin1 encoding                   |
| us-ascii           | ANSI encoding                     |
| GB18030            | GB18030 encoding (GBK range only) |
| Others             | Cannot be specified               |

If there is no parameter, the parameter does not have a value, or character encoding that cannot be specified for the parameter is defined, the KAVB8715-W message is output, and the initial value is set.

From=*source-email-address*

Defines the source email address of an email notification.

The initial value is the null character ("").

Only one source email address can be defined.

This item cannot be omitted.

Specify the source email address from 1 to 256 bytes.

The following table lists the permitted characters.

Table 2–71: Character encoding that can be used for From

| Characters that can be used      | Description        |
|----------------------------------|--------------------|
| One-byte alphanumeric characters | 0 to 9, and a to z |
| @                                | At mark (0x40)     |
| .                                | Period (0x2e)      |
| -                                | Hyphen (0x2d)      |
| _                                | Underscore (0x5f)  |

If there is no essential parameter, the parameter does not have a value, a character that cannot be specified for a parameter is defined, a parameter is not in the RFC822 format, or a parameter is exceeding the maximum length, the KAVB8714-E message is output and the operation terminates abnormally.

DefaultTo=*default-destination-email-address* [, *default-destination-email-address* . . .]

Defines the default destination email address.

The initial value is the null character ("").

You can define 20 destination email addresses. To specify multiple email addresses, separate them by a comma (,).

A single-byte space or tab between an email address and a comma (,) is ignored.

Consecutive commas (,) are treated as a comma, and commas at the beginning and at the end are ignored. If the same email address is specified more than once, the email message is sent to the specified address only once.

This parameter can be omitted. If omitted, the -to option of the *jimmail* command must be specified.

If both the DefaultTo parameter and the -to option of the *jimmail* command are specified, the -to option is prioritized.

Specify the destination email address from 1 to 256 bytes.

The characters that can be used for the source email address can be used.

If unusable characters are specified, the parameter is not in the RFC822 format, or the parameter exceeds the maximum length, the KAVB8714-E message is output, and the operation terminates abnormally.

Also, if neither the `DefaultTo` parameter nor the `-to` option of the `jimmail` command is specified, the KAVB8712-E message is output, and the operation terminates abnormally.

`SmtPServer=SMTP-server-name`

Defines the host name or the IP address of the SMTP server to connect when sending an email. Configure one of the following files to enable successful host name resolution of *SMTP-server-name*:

- The `jp1hosts` file in JP1/Base on the manager host
- The `jp1hosts2` file in JP1/Base on the manager host
- The `hosts` file or DNS

For the IP address, only IPv4 addresses can be specified. IPv6 addresses cannot be specified.

The initial value of the `SmtPServer` parameter is the null character ("").

Specify only one SMTP server name across the system.

This parameter cannot be omitted.

Specify 1 to 255 of one-byte characters for the host name.

If there is no essential parameter, the parameter does not have a value, a character that cannot be used for a parameter is defined, or the parameter exceeds the maximum length, the KAVB8714-E message is output, and the operation terminates abnormally.

`SmtPPort=SMTP-port-number`

Defines the port number of the communication port for the SMTP server.

The initial value for the `SmtPPort` parameter is 25. If you could not obtain the value, 25 is assumed. Specify the port number from 1 to 65535.

If you define `NONE` or `POP` for `AuthMethod`, this item takes effect.

If there is no parameter, the parameter does not have a value, a character other than a numeric value is specified for the parameter, or a value outside the range is specified for the parameter, the KAVB8715-W message is output. The command continues processing, assuming the initial value.

`AuthMethod=authentication-method-for-sending-email`

Defines the authentication method for sending an email.

This parameter cannot be omitted.

Use the value listed in the table below for the authentication method. The initial value is `NONE`.

**Table 2–72: Authentication method for `AuthMethod`**

| Value of <code>AuthMethod</code> | Authentication method          |
|----------------------------------|--------------------------------|
| <code>NONE</code>                | No authentication              |
| <code>POP</code>                 | POP before SMTP authentication |
| <code>SMTP</code>                | SMTP-AUTH authentication       |

Depending on the authentication method for sending an email, the items that must be set for the email environment definition file vary.

If there is no essential parameter, the parameter does not have a value, or a value outside the range is specified for the parameter, the KAVB8714-E message is output, and the operation terminates abnormally.

The following table lists the setting items for each `AuthMethod` value.

**Table 2–73: Setting items when AuthMethod is NONE**

| Parameter name     | Setting | Omission   | Value assumed when omitted |
|--------------------|---------|------------|----------------------------|
| Charset            | Y       | Possible   | iso-8859-1                 |
| From               | Y       | Impossible | --                         |
| DefaultTo          | Y       | Possible   | " "                        |
| AuthMethod         | Y       | Impossible | --                         |
| SmtpServer         | Y       | Impossible | --                         |
| SmtpPort           | Y       | Possible   | 25                         |
| SmtpAuthPort       | N       | --         | --                         |
| Pop3Server         | N       | --         | --                         |
| Pop3Port           | N       | --         | --                         |
| AuthUser           | N       | --         | --                         |
| AuthPassword       | N       | --         | --                         |
| ConnectTimeout     | Y       | Possible   | 10,000                     |
| SoTimeout          | Y       | Possible   | 10,000                     |
| MailSubjectCutting | Y       | Possible   | OFF                        |
| MailNewLine        | Y       | Possible   | CRLF                       |

Legend:

Y: Must be set.

N: Not necessary to be set.

**Table 2–74: Setting items when AuthMethod is POP**

| Parameter name     | Setting | Omission   | Value assumed when omitted |
|--------------------|---------|------------|----------------------------|
| Charset            | Y       | Possible   | iso-8859-1                 |
| From               | Y       | Impossible | --                         |
| DefaultTo          | Y       | Possible   | " "                        |
| AuthMethod         | Y       | Impossible | --                         |
| SmtpServer         | Y       | Impossible | --                         |
| SmtpPort           | Y       | Possible   | 25                         |
| SmtpAuthPort       | N       | --         | --                         |
| Pop3Server         | Y       | Impossible | --                         |
| Pop3Port           | Y       | Possible   | 110                        |
| AuthUser           | Y       | Impossible | --                         |
| AuthPassword       | Y       | Impossible | --                         |
| ConnectTimeout     | Y       | Possible   | 10,000                     |
| SoTimeout          | Y       | Possible   | 10,000                     |
| MailSubjectCutting | Y       | Possible   | OFF                        |
| MailNewLine        | Y       | Possible   | CRLF                       |

Legend:

Y: Must be set.

N: Not necessary to be set.

Table 2–75: Setting items when AuthMethod is SMTP

| Parameter name     | Setting | Omission   | Value assumed when omitted |
|--------------------|---------|------------|----------------------------|
| Charset            | Y       | Possible   | iso-8859-1                 |
| From               | Y       | Impossible | --                         |
| DefaultTo          | Y       | Possible   | " "                        |
| AuthMethod         | Y       | Impossible | --                         |
| SmtpServer         | Y       | Impossible | --                         |
| SmtpPort           | N       | --         | --                         |
| SmtpAuthPort       | Y       | Impossible | 587                        |
| Pop3Server         | N       | --         | --                         |
| Pop3Port           | N       | --         | --                         |
| AuthUser           | Y       | Impossible | --                         |
| AuthPassword       | Y       | Impossible | --                         |
| ConnectTimeout     | Y       | Possible   | 10,000                     |
| SoTimeout          | Y       | Possible   | 10,000                     |
| MailSubjectCutting | Y       | Possible   | OFF                        |
| MailNewLine        | Y       | Possible   | CRLF                       |

Legend:

Y: Must be set.

N: Not necessary to be set.

SmtpAuthPort=*SMTP-AUTH-authentication-submission-port-number*

Defines the submission port number of the communication port for the SMTP-AUTH authentication. The initial value is 587. If you cannot obtain the value, 587 is assumed. Specify a value from 1 to 65535.

When using the SMTP-AUTH authentication, specify the number of the destination port used by the SMTP server to connect for the SmtpAuthPort parameter if the connection email server does not use the submission port.

When you define SMTP for AuthMethod, this item takes effect.

If this parameter does not exist, the parameter does not have a value, characters other than numeric values are specified for the parameter, or a value outside the range is specified for the parameter, the KAVB8715-W message is output. The command continues processing, assuming the initial value.

Pop3Server=*POP3-server-name*

Defines the host name or the IP address of the POP3 server to be used for POP before SMTP authentication. Configure one of the following files to enable successful host name resolution of *POP3-server-name*:

- The `jp1hosts` file in JP1/Base on the manager host
- The `jp1hosts2` file in JP1/Base on the manager host
- The `hosts` file or DNS

For the IP address, IPv4 addresses can be specified. IPv6 addresses cannot be specified.

If the email server serves as both the SMTP server and the POP3 server, specify the SMTP server name specified for `SmtpServer`.

Specify only one POP3 server name across the system.

Specify 1 to 255 one-byte characters as the host name of the POP3 server. The initial value is the null character (""). Characters you can use as the host name of the POP3 server are the characters that can be used for the host name of the SMTP server.

If you define POP for `AuthMethod`, this item takes effect. When it takes effect, you must specify this parameter.

If there is no essential parameter, the parameter does not have a value, characters that cannot be specified for the parameter are specified, or the parameter exceeds the maximum length, the KAVB8714-E message is output, and the operation terminates abnormally.

`Pop3Port=POP3-port-number`

Defines the port number of the communication port for the POP3 server to use for the POP before SMTP authentication.

The initial value for the parameter is 110. If you cannot obtain the value, 110 is assumed. Specify a value from 1 to 65535 for the port number.

If you define POP for `AuthMethod`, this item takes effect.

If there is no parameter, the parameter does not have a value, characters other than numeric values are specified for the parameter, or a value outside the range is specified for the parameter, the KAVB8715-W is output, and the initial value is assumed.

`AuthUser=authentication-account-name`

The `AuthUser` parameter defines the authentication account name to use for the POP before SMTP or SMTP-AUTH authentication.

Specify 1 to 255 one-byte characters for the authentication account name.

The initial value is the null character ("").

If you specify POP or SMTP for the `AuthMethod` parameter, this item takes effect.

If there is no essential parameter, the parameter does not have a value, characters (multi-byte) that cannot be used for the parameter are defined, or the parameter exceeds the maximum length, the KAVB8714-E message is output, and the operation terminates abnormally.

`AuthPassword=authentication-password`

For the `AuthPassword` parameter, the authentication password for the POP before SMTP or SMTP-AUTH authentication is set.

The authentication password for the `AuthPassword` parameter is set by using the `jimailpasswd` command.

If you edit the email environment definition file, and set a password in plain text for the `AuthPassword` parameter, you cannot log in to the email server because the authentication password does not match when connecting to the email server.

If you specify POP or SMTP for the `AuthMethod` parameter, this item takes effect.

If there is no essential parameter, the parameter does not have a value, characters (multi-byte) that cannot be used for the parameter are specified, or the parameter exceeds the maximum length, the KAVB8714-E message is output, and the operation terminates abnormally.

`ConnectTimeout=network-connection-timeout-period`

For the `ConnectTimeout` parameter, define the timeout period in milliseconds for waiting until connection between the SMTP and POP3 servers is established. The initial value is 10,000 milliseconds (10 seconds).

Specify 1,000 to 3,600,000 (1 to 3,600 seconds) for the timeout period.

Change this value only when a timeout occurs with the initial value according to the operating environment.

If there is no parameter, the parameter does not have a value, a character string other than numeric characters is specified for the parameter, or a value outside the range is specified for the parameter, the KAVB8715-W message is output, and the initial value is assumed.

`SoTimeout=communication-timeout-period`

Define the timeout period in milliseconds until a response is received from the SMTP and POP3 servers for the `SoTimeout` parameter. The initial value is 10,000 milliseconds (10 seconds).

Specify a value from 1,000 to 3,600,000 (1 to 3,600 seconds) as the timeout period.

Only when a communication timeout error occurs with the initial value, change the value according to the operating environment.

If there is no parameter, the parameter does not have a value, a character string other than numeric characters is specified for the parameter, or a value outside the range is specified for the parameter, the KAVB8715-W message is output, and the initial value is assumed.

`MailSubjectCutting=email-subject-drop-setting`

For the `MailSubjectCutting` parameter, define whether to drop the email subject, and forcibly send the email if the email subject exceeds the maximum length when sending the email.

- When `OFF` is set, the email subject is not dropped, and the `jimmail` command terminates abnormally.
- When `ON` is set, drops the email subject according to the character encoding specified for the `Charset` parameter within 512 bytes, and continues sending the email.

The initial value is `OFF`. The setting value is not case sensitive.

If there is no parameter, the parameter does not have a value, or a value other than `ON` and `OFF` is specified, the KAVB8715-W message is output, and the initial value is assumed.

`MailNewLine=email-linefeed-code`

For the `MailNewLine` parameter, define the linefeed code to be used in the text of an email. The `jimmail` command replaces the linefeed code (`\n`) specified for the optional argument of the command with the linefeed code specified for this parameter before sending the email. The initial value is `CRLF`.

The setting value is not case sensitive.

The linefeed code is regulated as `CRLF` in RFC. Do not change the initial value if you do not have specific reasons. On some email servers, if linefeed codes other than `CRLF` are used, email messages might not be sent, or a line in email contents might not be broken.

The linefeed codes are defined by using the values listed in the following table.

**Table 2–76: Setting value for MailNewLine**

| Setting value     | Description                        |
|-------------------|------------------------------------|
| <code>CRLF</code> | <code>CR (0x0d) + LF (0x0a)</code> |
| <code>LF</code>   | <code>LF (0x0a)</code>             |
| <code>CR</code>   | <code>CR (0x0d)</code>             |

If there is no parameter, the parameter does not have a value, or a value outside the range is defined for the parameter, the KAVB8715-W message is output, and the initial value is assumed.

## Example

The following is the email environment definition file for a Japanese environment immediately after installation:

```
Charset=iso-2022-jp
From=
```

```
DefaultTo=  
SmtpServer=  
SmtpPort=25  
AuthMethod=NONE  
SmtpAuthPort=587  
Pop3Server=  
Pop3Port=110  
AuthUser=  
AuthPassword=  
ConnectTimeout=10000  
SoTimeout=10000  
MailSubjectCutting=OFF  
MailNewLine=CRLF
```

The following is the email environment definition file for a non-Japanese environment immediately after installation:

```
Charset=iso-8859-1  
From=  
DefaultTo=  
SmtpServer=  
SmtpPort=25  
AuthMethod=NONE  
SmtpAuthPort=587  
Pop3Server=  
Pop3Port=110  
AuthUser=  
AuthPassword=  
ConnectTimeout=10000  
SoTimeout=10000  
MailSubjectCutting=OFF  
MailNewLine=CRLF
```

## ◆ Display message change definition file (jcochmsg.conf)

### Format

```
DESC_VERSION=1  
# Display-message-change-definition-comment  
def definition-name-1  
  [cmt comment]  
  [define {enable | disable}]  
  [addflag {true | false}]  
  cnd  
    event-condition  
  end-cnd  
  msg message  
end-def  
  
def definition-name-2  
  [cmt comment]  
  [define {enable | disable}]  
  [addflag {true | false}]  
  cnd  
    event-condition
```

```
end-cnd
msg message
end-def
```

## File

`jcochmsg.conf` (display message change definition file)

`jcochmsg.conf.model` (model file for the display message change definition file)

## Storage directory

In Windows

For a physical host:

*Console-path*\conf\chattr\jcochmsg.conf

For a logical host:

*shared-folder*\jplcons\conf\chattr\jcochmsg.conf

In UNIX

For a physical host:

*/etc/opt/jplcons/conf/chattr/jcochmsg.conf*

For a logical host:

*shared-directory*/jplcons/conf/chattr/jcochmsg.conf

## Description

This file defines the JP1 event conditions that change the display of a message using the display message change function and defines the message after the change. JP1 event attributes that match event conditions are changed in accordance with the definitions in this file. Specify this file using the language encoding that is used by JP1/IM - Manager.

The maximum size of this file is 22 megabytes (23,068,672 bytes).

There are two types of parameters in the display message change definition file:

- Display message change definition file version  
Defines the format version of the display message change definition file.
- Display message change definition parameter  
Defines a condition for the JP1 events whose display message is to be changed and the display message after the change. The higher a display message change definition appears in the display message change definition file, the higher its priority.

## When the definitions are applied

The definition takes effect when the event display message change function is enabled, and one of the following operations is performed:

- JP1/IM - Manager is restarted
- The `jco_spmc_reload` command is executed
- The **OK** button is clicked in the Add Display Message Change Definition Settings window opened from the **Display Message Change Definition Settings** menu

- The **Apply** button is clicked in the View Display Message Change Definition window

## Information that is specified (display message change definition file version)

DESC\_VERSION

Specifies the file version that determines the format of this display message change definition file. Specify a value of 1. If DESC\_VERSION is omitted, 1 is assumed as the file version.

Specify DESC\_VERSION on the first line of the definition file (the first line in the file excluding any null lines and comment lines). If there is no file version in the first line, 1 is assumed.

## Information that is specified (display message change definition parameter)

As shown in the following figure, the definition parameter for changing the display message consists of a definition block and an event condition block.

Figure 2–10: Definition parameter for changing the display message

Multiple definition blocks can be specified. The number of definition blocks that can be specified is from 0 to 3,000. If the number of definition blocks exceeds the maximum, message KAVB4640-W is output, and processing continues, ignoring the definition blocks after number 3,000.

### def to end-def (definition block)

These are the start and end parameters for a display message change definition. The block from `def` to `end-def` can be omitted, in which case the system assumes that messages are not to be changed for any JP1 events.

After `def`, specify the names of display message change definitions. If you specify

`def Δ Δ Δ definition-1 Δ Δ Δ definition-2 Δ Δ Δ`, then `Δ Δ definition-1 Δ Δ Δ definition-2 Δ Δ Δ` are treated as the definition names (Δ indicates a single-byte space).

For a definition name, specify a character string of from 1 to 50 bytes. Each definition name must be unique within the display message change definition file. The permitted characters are all characters other than the control characters (from 0x00 to 0x1F and 0x7F to 0x9F).

### cmt comment

Describes the comment for the display message change definition. The comment specified for `cmt` is displayed in the comment section of the Display Message Change Definition Settings window. Only one `cmt` parameter can be specified in the definition block. This parameter can be omitted. Specify the comment using up to 1,024 bytes. The permitted characters are all characters other than the control characters (from 0x00 to 0x1F and 0x7F to 0x9F).

### define {enable | disable}

Specifies whether to enable the display message change definition. Only one `define` parameter can be specified in the definition block. To enable the display message change definition, specify `enable`, to disable it, specify `disable`. The `define` parameter can be omitted. By default, `enable` is set. The values are not case sensitive.

addflag {true | false}

Indicates an additional display message change definition has been added from a window, and specifies whether the display message change definition is an additional display message change definition. Therefore, to edit the additional display message change definition file, you do not need to specify the addflag parameter. Only one addflag parameter can be specified in the definition block. Specify true for the additional display message change definition, and false for the display message change definition. When true is specified, the icon (  ) is displayed in **Type** of the View Display Message Change Definition window. The addflag parameter can be omitted. By default, false is set. The values are not case sensitive.

cnd to end-cnd (event condition block)

These are the start and end parameters for the block that specifies a condition for the JP1 events whose display message is to be changed. You must specify at least one event condition block in a definition block. The event condition block cannot be omitted. If a received JP1 event satisfies multiple event conditions, the definition block closest to the beginning of the display message change definition file is used. Tabs and spaces before and after the cnd and end-cnd parameters are ignored.

*event-condition*

Specifies a condition for the JP1 events whose display message is to be changed. You can specify from 1 to 256 event conditions per event condition block. When multiple event conditions are specified, it is assumed that they are connected with the AND condition. Specify an event condition in the following format (Δ indicates a single-byte space):

*attribute-name*Δ*comparison-keyword*Δ*operand* [Δ*operand*] . . .

Note that a line consisting of only spaces or tabs is ignored during processing.

*attribute-name*

Specifies the name of the attribute that you want to compare. To specify a basic attribute, place B . immediately before the name. To specify an extended attribute (common information or user-specific information), place E . immediately before the name. Uppercase and lowercase are distinguished.

The following table lists and describes the combinations of attribute names and comparison keywords and the operands that can be specified.

Table 2–77: Combinations of attribute names and comparison keywords and the operands that can be specified

| No. | Item                    | Attribute name | Comparison keyword                                                           | Operand                                                                                                                                                                  |
|-----|-------------------------|----------------|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Event ID                | B.ID           | <ul style="list-style-type: none"><li>Match</li><li>Does not match</li></ul> | A maximum of 100 of these items can be specified.<br>Specify the event ID in hexadecimal notation. Letter case is ignored.<br>The permitted range is from 0 to 7FFFFFFF. |
| 2   | Reason for registration | B.REASON       | <ul style="list-style-type: none"><li>Match</li><li>Does not match</li></ul> | A maximum of 100 of these items can be specified.                                                                                                                        |
| 3   | Source process ID       | B.PROCESSID    | <ul style="list-style-type: none"><li>Match</li><li>Does not match</li></ul> | A maximum of 100 of these items can be specified.<br>The permitted range is from -2,147,483,648 to 2,147,483,647.                                                        |
| 4   | Source user ID          | B.USERID       | <ul style="list-style-type: none"><li>Match</li><li>Does not match</li></ul> | A maximum of 100 of these items can be specified.<br>The permitted range is from -2,147,483,648 to 2,147,483,647.                                                        |

| No. | Item                                                  | Attribute name | Comparison keyword                                                                                                                                                                                | Operand                                                                                                                                                                                             |
|-----|-------------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | Source group ID                                       | B.GROUPID      | <ul style="list-style-type: none"> <li>• Match</li> <li>• Does not match</li> </ul>                                                                                                               | <p>A maximum of 100 of these items can be specified.</p> <p>The permitted range is from -2,147,483,648 to 2,147,483,647.</p>                                                                        |
| 6   | Source user name                                      | B.USERNAME     | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Does not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 of these items can be specified, unless a regular expression is used, in which case only one item is allowed.                                                                      |
| 7   | Source group name                                     | B.GROUPNAME    | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Does not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 of these items can be specified, unless a regular expression is used, in which case only one item is allowed.                                                                      |
| 8   | Event-issuing server name (source host) <sup>#1</sup> | B.SOURCESERVER | <ul style="list-style-type: none"> <li>• First characters</li> <li>• Match</li> <li>• Does not match</li> <li>• Is contained</li> <li>• Is not contained</li> <li>• Regular expression</li> </ul> | A maximum of 100 of these items can be specified, unless a regular expression is used, in which case only one item is allowed.                                                                      |

| 22  | Program-specific extended attribute <sup>#2</sup> | E.xxxxxxx        | <ul style="list-style-type: none"> <li>First characters</li> <li>Match</li> <li>Does not match</li> <li>Is contained</li> <li>Is not contained</li> <li>Regular expression</li> </ul> | <p>For the attribute name, you can specify a name with a maximum length of 32 bytes that begins with an uppercase letter and consists of uppercase letters, numeric characters, and the underscore (_).</p> <p>A maximum of 100 of these items can be specified, unless a regular expression is used, in which case only one item is allowed.</p> |

#1

If the integrated monitoring database and the IM Configuration Management database are enabled, and the comparison keyword is Match or Do not match, the business group name can be specified in a path format.

If the integrated monitoring database and the IM Configuration Management database are disabled, and a comparison keyword other than Match and Do not match is selected, a business group name specified in a path format is treated as a host name.

If the `-ignorecasehost` option of the `jcoimdef` command is set to ON, and a comparison keyword other than Regular expression is selected, the character string is no longer case sensitive.

#2

You can also specify a JP1 product-specific extended attribute. For example, the program-specific extended attribute for the JP1/AJS job execution host is E.C0. For details about the product-specific extended attributes, consult the documentation for the products that issue JP1 events.

#### *comparison-keyword*

Specifies one of BEGIN (begins with), IN (matches), NOTIN (does not match), SUBSTR (includes), NOTSUBSTR (does not include), or REGEX (regular expression) as the comparison keyword. The comparison keyword is case sensitive.

#### *operand*

Specifies a character string as the value that is to be compared with the attribute value as specified by the comparison keyword. Operands are case sensitive.

Separate multiple operands with one or more consecutive spaces or a tab. The OR condition is applied to the specified operands. Note that if a regular expression is specified, only one operand can be specified.

To specify a single-byte space, a tab, end-of-line code (CR or LF), or % as part of an operand, specify as follows:

| No. | Value to be set                | How to specify |
|-----|--------------------------------|----------------|
| 1   | Tab (0x09)                     | %09            |
| 2   | Space (0x20)                   | %20            |
| 3   | % (0x25)                       | %25            |
| 4   | Linefeed code LF (0x0a)        | %0a            |
| 5   | Carriage return code CR (0x0d) | %0d            |

During maximum value checking for the definition format, %20 and %25 are each treated as a single character. The character code specified after the % is not case sensitive. The following shows an example of defining ID matches 100 and 200, which selects multiple operands:

B.IDΔINΔ100Δ200

Legend: Δ indicates a single-byte space (0x20)

You can specify a maximum of 4,096 bytes of operands per event condition and per event condition block (total length of operands in bytes that are specified in the event condition block).

#### *msg*

This parameter describes the message to be displayed.

You must specify one msg parameter in a definition block. The parameter cannot be omitted.

The msg parameter cannot exceed 1,023 bytes. The permitted characters are all characters other than the control characters (from 0x00 to 0x1F and 0x7F to 0x9F).

If a msg parameter is specified outside of the definition block, message KAVB4629-W is output, the msg parameter specification is ignored, and processing continues.

In the circumstances listed below, message KAVB4631-W is output, and processing continues, ignoring the definition block that produced the error.

- The msg parameter is omitted
- The msg parameter is specified more than once
- The message specified in the msg parameter exceeds 1,023 bytes
- The message specified in the msg parameter includes control characters

To specify a variable in the message after the change, use a format such as \$EVSEV. The variable will be replaced with the actual value of the attribute value in the event.

The following table describes the available variables.

| Type of information                                            | Variable name               | Description                                                                                                                          |
