| 3F88     | Trend data management service restart failed during the trend data deletion process                                     | KAJY62009-E An attempt to restart the trend management service after deleting trend data failed. (JP1 user name : <i>JP1-user-name</i> , JP1/IM-Manager host name : <i>JP1/IM-Manager-host-name</i> , deletion target host name : <i>deletion-target-host-name</i> )                                                                                                                                                                                                                             | Trend data deletion function                      |

#1: These are dummy events to which the following limitations apply:

- The event cannot be searched in the Event Console window.

- If the details of the event are displayed, the JP1 event basic and extended attributes are not displayed.
- No action is executed pursuant to such an event even if an automated action is set.
- No mapping is performed on the event even if event information mapping is defined.
- This event is not subject to monitor startup.
- This event is not subject to the event acquisition filter.
- This event is not subject to correlation event generation processing.
- This event is not registered in the event database. Therefore, when JP1/IM - Manager is restarted, this event is no longer displayed in the Event Console window.
- If you change the event action status, the changes are not applied to other parts of JP1/IM - View.

#2: When recovery of JP1/Base Event Service (`jevservice`) is detected, the following message is displayed: KAVB8063-I.

#3: The following limitation applies to these events:

- No action is executed on this event even if an automated action is set.

#4: The following limitation applies to these events:

- This event is not subject to the event acquisition filter.

#5: This is a JP1 event issued by JP1/Base command execution. For details about the JP1 events, see the chapter that describes JP1 events in the *JP1/Base User's Guide*.

#6: For details about JP1 events issued by log file traps of JP1/Base instead of the remote monitoring function, see the chapter describing JP1 events in the *JP1/Base User's Guide*.

#7: For details about JP1 events issued by log file traps of JP1/Base instead of the remote monitoring function, see the chapter describing JP1 events in the *JP1/Base User's Guide*.

#8: This event is issued only if issuance of JP1 events in response to process errors is set. To issue such JP1 events, you must edit the IM parameter definition file and then execute the `jbssetcnf` command. For details about definition files, see [IM parameter definition file \(`jp1co\_param\_V7.conf`\)](#) in *Chapter 2. Definition Files*. For details about the setting procedure, see *1.19.6 Specifying settings for handling JP1/IM - Manager failures (for Windows)*, and *2.18.10 Specifying settings for handling JP1/IM - Manager failures (for UNIX)* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

#9: *Original event* refers to the event that JP1/IM - Manager acquired from JP1/Base.

## 3.2.2 Details of JP1 events output by JP1/IM - Manager

This section describes the details of JP1 events.

### (1) Details of event ID: 0002010

| Attribute type  | Item              | Attribute name | Description                                                                                                               |
|-----------------|-------------------|----------------|---------------------------------------------------------------------------------------------------------------------------|

|                    |                                               | Source event server name of the handled event | PROCESSUPDATE_SOURCESERVER  | Name of the event-issuing server (server that issued the JP1 event whose action's status was changed)                                                                                                                                                                                         |
|                    |                                               | Message for the handled event                 | PROCESSUPDATE_MESSAGE       | Message (for the JP1 event whose action's status was changed)                                                                                                                                                                                                                                 |

| Attribute type |  | Item                                   | Attribute name     | Description                                                                                                                                                            |
|----------------|--|----------------------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |  | Registration time of the handled event | PROCESSUPDATE_TIME | Time of registration (time the JP1 event whose action's status was changed was registered; displayed in the Event Details window in the format <i>MM/DD hh:mm:ss</i> ) |

#1: The substitute user ID and substitute group ID specified in the event server settings file of JP1/Base are set. If they are not specified, -1 is set.

#2: The value that is actually displayed for *JP1-user* depends on the status, as follows:

- When the action status was changed from JP1/IM - View version 08-01 or later: *JP1-user-who-changed-the-action-status*
- When the action status was changed from JP1/IM - View version 07-00 or earlier: -
- When the action status was changed by the `jcochstat` command: `jcochstat`
- When the action status was changed because there was a response to a response-waiting event: `system`
- When the action status was changed because a response-waiting event was canceled: `system`

#3: *status-before-action* and *status-after-action* depend on the handling method, as shown below:

- Processed: `PROCESSED`
- Unprocessed: `UNPROCESSED`
- Processing: `PROCESSING`
- Held: `HELD`
- Processed -> Deleted: `PROCESSED+DELETE`
- Unprocessed -> Deleted: `UNPROCESSED+DELETE`
- Processing -> Deleted: `PROCESSING+DELETE`
- Held -> Deleted: `HELD+DELETE`

## (35) Details of event ID: 00003F13

Note: JP1 event 00003F28 is output once when the number of JP1 event sets reaches the maximum value. After that, this event is not output again until the number of JP1 event sets drops down to 16,000 or fewer.

#: The substitute user ID and substitute group ID specified in the event server settings file of JP1/Base are set. If they are not specified, -1 is set.

## (48) Details of event ID: 00003F31

|                    |                                               | Occurrence                              | OCCURRENCE     | NOTICE                                                                                                                                                                                                                                                                                                                                                                                                         |
|                    | User-specific or program-specific information | Duplicate attribute value information 1 | SAMEATTR1      | Stores the first (listed at the top) attribute name and its value as a duplicate attribute value condition in <i>attribute-name=attribute-value</i> format. If a duplicate attribute value condition is not specified, a blank is stored. You can specify a maximum of 1,024 bytes for the attribute value. For a value larger than 1,024 bytes, split it, but do so without splitting a multi-byte character. |
|                    |                                               | Duplicate attribute value information 2 | SAMEATTR2      | Stores the second attribute name and its value as a duplicate attribute value condition in <i>attribute-name=attribute-value</i> format. If there are fewer than two duplicate attribute value conditions, a blank is stored. You can specify a maximum of 1,024 bytes for the attribute value. For a value larger than 1,024 bytes, split it, but do so without splitting a multi-byte character.             |
|                    |                                               | Duplicate attribute value information 3 | SAMEATTR3      | Stores the third attribute name and its value as a duplicate attribute value condition in <i>attribute-name=attribute-value</i> format. If there are fewer than three duplicate attribute value conditions, a blank is stored. You can specify a maximum of 1,024 bytes for the attribute value. For a value larger than 1,024 bytes, split it, but do so without splitting a multi-byte character.            |

#: The substitute user ID and substitute group ID specified in the event server settings file of JP1/Base are set. If they are not specified, -1 is set.

<sup>#1</sup>: The substitute user ID and substitute group ID specified in the event server settings file of JP1/Base are set. If they are not specified, -1 is set.

<sup>#2</sup>: The format of *arrival-time* is replaced in the KAVB4600-I message with *YYYY/MM/DD hh:mm:ss*. The time set in *arrival-time* is based on the time zone set in the machine where JP1/IM - Manager is running.

## (61) Details of event ID: 00003F63

#1: The substitute user ID and substitute group ID specified in the event server settings file of JP1/Base are set. If they are not specified, -1 is set.

#2: The format of *arrival-time* is replaced in the KAVB4623-I message with *YYYY/MM/DD hh:mm:ss*. The time set in *arrival-time* is based on the time zone set in the machine where JP1/IM - Manager is running.

|                    |                                               | Monitoring node status <sup>#1</sup>                                         | MON_NODE_STATUS   | StatusID of the monitoring node                                                                                                   |
|                    |                                               | Information about the JP1 event resulting in the status change <sup>#2</sup> | <i>attributes</i> | Attributes (the name of a basic attribute is prefixed with JCS_B_, and the name of an extended attribute is prefixed with JCS_E_) |

#1: For the monitoring node status (E.MON\_NODE\_STATUS), the status of the monitoring node that issued the JP1 event is stored in StatusID, expressed as a numeric value as shown below:

Value of StatusID (monitoring node status):

Emergency: 800; Alert: 700; Critical: 600; Error: 500; Warning: 400; Normal: 300; Debug: 200; Initial: 100

For example, if a JP1 event is issued when the monitoring node status has changed to Emergency, its monitoring node status (E.MON\_NODE\_STATUS) would be 800.

#2: The item *Information about the JP1 event resulting in the status change* cannot be checked by JP1/IM - View. All information about the JP1 event resulting in the status change is stored in this item as sets of *attribute-name-attribute-value*. If 00003FB0 exceeds the maximum length for a JP1 event (10,000 bytes), JP1/IM stores as much JP1 event information as fits. If the number of extended attributes exceeds 100, JP1/IM stores as much JP1 event information as fits, but no more than 100 extended attributes. The attributes E.JCS\_B\_TIME (registration time of the JP1 event resulting in the status change) and E.JCS\_B\_ARRIVEDTIME (arrival time of the JP1 event resulting in the status change) are stored in this item in GMT in the format *YYYY/MM/DD hh:mm:ss*.

## (73) Details of event ID: 00003FB1

Legend:

--: None

#: Only one JP1 event with event ID 00003FB1 is issued even if a single JP1 event triggered more than 100 status change events from multiple monitoring objects. A maximum of 10 monitoring object IDs can be listed in *monitoring-node-ID* in the message, separated by the comma. If there are more than 10 monitoring object IDs, . . . is displayed following the last listed ID.

Legend:

--: None

#1: If the message DLL in which the description of an event log is coded is not set correctly, the inserted phrase or the detail code is enclosed in double-quotation marks (") to register it in a JP1 event message.

#2: An attribute that exists only when the common definition (ATTR\_EVENT\_LOGTRAP\_SOURCEHOST) is 1.

Legend:

--: None

#1: The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

#2: If the message exceeds 1,024 bytes, only the characters up to 1,023 bytes are set. If the 1,023<sup>rd</sup> byte happens to constitute part of a multi-byte character, the message is set with that multi-byte character and the subsequent characters discarded.

#3: If the total size of the extended attributes exceeds 10,000 bytes, the value of this attribute is truncated to make the total size 10,000 bytes, with the last three bytes converted to an ellipsis (. . .).

## (103) Details of event ID: 00003FE1

Legend:

--: None

#1: The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

#2: If the message exceeds 1,024 bytes, only the characters up to 1,023 bytes are set. If the 1,023<sup>rd</sup> byte happens to constitute part of a multi-byte character, the message is set with that multi-byte character and the subsequent characters discarded.

#3: If the total size of the extended attributes exceeds 10,000 bytes, the value of this attribute is truncated to make the total size 10,000 bytes, with the last three bytes converted to an ellipsis (. . .).

## (104) Details of event ID: 00003FE2

Legend:

--: None

#1: The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

#2: If the message is 1,024 bytes or more, a string truncated to 1,023 bytes or less is set.

"If byte 1,023 is in the middle of a multibyte character, that character is also truncated."

#3: If the total size of the extended attributes exceeds 10,000 bytes, the value of this attribute is truncated to make the total size 10,000 bytes, with the last three bytes converted to an ellipsis (...).

## (105) Details of event ID: 00003FF0

Legend:

--: None

#1: The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

#2: If the message is 1,024 bytes or more, a string truncated to 1,023 bytes or less is set. If byte 1,023 is in the middle of a multibyte character, that character is also truncated.

#3: This JP1 event is associated with the manager node. In a configuration with more than one manager, only the directly connected manager node is associated with it.

|                | User-specific or program-specific information | Execution source host name | EXEC_HOST      | JP1/IM - Manager host name from which Delete trend data operation was performed. Displays the Integrated Manager host name if you have deleted Trend data Management Database trend data for lower manager host from the Integration Manager. Otherwise, JP1/IM - Manager hostname of the message is displayed. |

Legend:

--: None

#1: The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

#2: If the message is 1,024 bytes or more, a string truncated to 1,023 bytes or less is set. If byte 1,023 is in the middle of a multibyte character, that character is also truncated.

#3: This JP1 event is associated with the manager node. In a configuration with more than one manager, only the directly connected manager node is associated with it.

## (125) Details of event ID: 00003F88

|                | User-specific or program-specific information | Execution source host name | EXEC_HOST      | JP1/IM - Manager host name from which Delete trend data operation was performed. Displays the Integrated Manager host name if you have deleted Trend data Management Database trend data for lower manager host from the Integration Manager. Otherwise, JP1/IM - Manager hostname of the message is displayed. |

Legend:

--: None

#1: The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

#2: If the message is 1,024 bytes or more, a string truncated to 1,023 bytes or less is set. If byte 1,023 is in the middle of a multibyte character, that character is also truncated.

#3: This JP1 event is associated with the manager node. In a configuration with more than one manager, only the directly connected manager node is associated with it.

### 3.2.3 Lists of JP1 events output by JP1/IM - Agent

#### (1) Attributes of JP1 events that monitor and issue performance data

The following is a list of attributes of JP1 events that monitor and issue performance data.

Table 3–3: List of attributes of JP1 events that monitor and issue performance data

| Category                                 | Item         | Name Attribute | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## (2) JP1 event issued that monitoring a textual log File

This JP1 event is issued when fluentd monitors the text-format log File and a log that Match the user-specified condition is output. For fluentd, see 3.15.3 *Log monitoring function by JP1/IM - Agent* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Table 3–4: Attributes for JP1 Events Issued by Monitoring Text-Format Log File

| Classification                           | Item                     | Attribute name     | Description                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------|--------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Basic attributes                         | Event ID                 | ID                 | Value specified for JP1 Event ID in monitoring text-formatted log file definition file. The default Value is "00007601".                                                                                                                                                                                                                                                                                                               |
|                                          | Message                  | MESSAGE            | Value captured by the name MESSAGE in text-formatted log file monitoring definition file's regular expressions for parsing logging.                                                                                                                                                                                                                                                                                                    |
| Extended Properties (Common Information) | Event level              | SEVERITY           | Value specified in Event level of monitoring text-formatted log file definition file.                                                                                                                                                                                                                                                                                                                                                  |

For details on setting method, see the description of the [Attributes Settings] section in the <i>Monitoring text-formatted log file definition file (fluentd_@@trapname@@_tail.conf.template)</i> in Chapter 2. <i>Definition Files</i> in the <i>JP1/Integrated Management 3 - Manager Command, Definition File and API Reference</i> . |

### (3) JP1 event to be issued by monitoring Windows event log

This is a JP1 event that is issued when fluentd monitors Windows event log and a log that Match the user-specified criteria is output. For fluentd, see 3.15.3 *Log monitoring function by JP1/IM - Agent* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Table 3–5: List of JP1 Event Attributes to Issue Monitoring Windows Event Logs

| Classification                           | Item                     | Attribute name   | Description                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------|--------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Basic attributes                         | Event ID                 | ID               | Value specified for JP1 Event ID in monitoring Windows event-log definition file. The default Value is "00007602".                                                                                                                                                                                                                                                                  |

|                | jp1_pc_nodel<br>abel | JPC_NODEL<br>ABEL  | Value specified in the label name of IM management node for monitoring Windows event-log definition file. |

#

NT logging type Setup is shown below.

- When NT Logging type" is Security  
Based on keyword's Value, Setup the following NT logging types in the format "Value of keyword : Setup String".  
0x10000000000000:Audit\_Success, 0x20000000000000:Audit\_Failure  
If the bitwise AND of Value is not 0, Setup string is Attribute value. If both are 0, "-" is Setup as Value.
- When NT Logging type" Is Not Security
- Based on level's Value, we Setup the following NT logging types in the format "Value of level : Setup String".  
1: Critical, 2:Error, 3:Warning, 4:Information, 5:Verbose, et al. : Information

## (4) JP1 Events Issued When JP1/IM agent control base is Disconnected

This JP1 event is issued when there is no connection from JP1/IM agent control base to JP1/IM agent management base for a certain period of time using polling monitoring function of JP1/IM agent control base. For details about JP1/IM agent control base's polling monitoring function, see 3.15.8 *Polling monitoring of JP1/IM agent control base* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Table 3–6: List of attributes for JP1 events issued when JP1/IM agent control base is disconnected

| Classification               | Item        | Attribute name | Description |
|------------------------------|-------------|----------------|-------------|
| Basic attributes             | Event ID    | ID             | 00007620    |
|                              | Message     | MESSAGE        | KNBC20043-E |
| Extended Properties (Common) | Event level | SEVERITY       | Error       |

| Classification                           | Item              | Attribute name  | Description                                                                                                                                                     |
|------------------------------------------|-------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Information )                            | Product name      | PRODUCT_NAME    | /HITACHI/JP1/JPCS2                                                                                                                                              |
|                                          | Object type       | OBJECT_TYPE     | IMAGTHC                                                                                                                                                         |
|                                          | Object name       | OBJECT_NAME     | IMAGENT                                                                                                                                                         |

| Extended Attribute (Unique Information ) | Event source host | JP1_SOURCE_HOST | Integrated agent host name on which JP1/IM agent control base has been installed that JP1/IM agent management base has not been connected for a period of time. |

## (5) JP1 Events to Issue When JP1/IM agent control base Is Connected

This JP1 event is issued when JP1/IM agent control base connects to JP1/IM agent management base using polling monitoring function of JP1/IM agent control base. For details about JP1/IM agent control base's polling monitoring function, see *3.15.8 Polling monitoring of JP1/IM agent control base* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Table 3–7: List of attributes for JP1 events that are issued when JP1/IM agent control base is connected

| Classification                            | Item              | Attribute name  | Description                                                                                                        |
|-------------------------------------------|-------------------|-----------------|--------------------------------------------------------------------------------------------------------------------|
| Basic attributes                          | Event ID          | ID              | 00007621                                                                                                           |
|                                           | Message           | MESSAGE         | KNBC20044-I                                                                                                        |
| Extended Properties (Common Information ) | Event level       | SEVERITY        | Information                                                                                                        |
|                                           | Product name      | PRODUCT_NAME    | /HITACHI/JP1/JPCS2                                                                                                 |
|                                           | Object type       | OBJECT_TYPE     | IMAGTHC                                                                                                            |
|                                           | Object name       | OBJECT_NAME     | IMAGENT                                                                                                            |
|                                           | Occurrence        | OCCURRENCE      | NOTICE                                                                                                             |
| Extended Attribute (Unique Information )  | Event source host | JP1_SOURCE_HOST | Integrated agent host name where JP1/IM agent control base connected to JP1/IM agent management base is installed. |

## (6) JP1 Events Issue When JP1/IM agent control base Stops on Normal

This JP1 event is issued when JP1/IM agent control base is stopped by polling monitoring function of JP1/IM agent control base. For details about JP1/IM agent control base's polling monitoring function, see *3.15.8 Polling monitoring of JP1/IM agent control base* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

**Table 3–8: List of attributes for JP1 events that are issued when JP1/IM agent control base is stopped normally**

| Classification                           | Item              | Attribute name | Description                                                                               |
|------------------------------------------|-------------------|----------------|-------------------------------------------------------------------------------------------|
| Basic attributes                         | Event ID          | ID             | 00007622                                                                                  |
|                                          | Message           | MESSAGE        | KNBC20045-I                                                                               |
| Extended Properties (Common Information) | Event level       | SEVERITY       | Information                                                                               |
|                                          | Product name      | PRODUCT_NAME   | /HITACHI/JP1/JPCS2                                                                        |
|                                          | Object type       | OBJECT_TYPE    | IMAGTHC                                                                                   |
|                                          | Object name       | OBJECT_NAME    | IMAGENT                                                                                   |
|                                          | Occurrence        | OCCURRENCE     | NOTICE                                                                                    |
| Extended Attribute (Unique Information)  | Event source host | JP1_SOURCEHOST | Integrated agent host name on which JP1/IM agent control base to be stopped is installed. |

## (7) JP1 Events Issue When Add of agent is detected

**Table 3–9: List of attributes for JP1 events that are issued when add for agent is detected**

| Classification   | Item                      | Attribute name | Description                              |
|------------------|---------------------------|----------------|------------------------------------------|
| Basic attributes | Event ID                  | --             | The default Value is "00007630" #1.      |
|                  | Serial number             | SEQNO          | Serial number                            |
|                  | Source process ID         | PROCESSID      | 0                                        |
|                  | Registered time           | TIME           | Time of registration                     |
|                  | Arrival time              | ARRIVEDTIME    | Time of arrival                          |
|                  | Source user ID            | USERID         | For -1 to 65,535#2                       |
|                  | Source group ID           | GROUPLD        | For -1 to 65,535#2                       |
|                  | Source user name          | USERNAME       | In Windows: SYSTEM<br>In UNIX: root      |
|                  | Source group name         | GROUPNAME      | In Windows: NULL string<br>In UNIX: root |
|                  | Event-issuing server name | SOURCESERVER   | Event-issuing server name                |

| Classification                   | Item                 | Attribute name | Description          |
|----------------------------------|----------------------|----------------|----------------------|
|                                  | Source serial number | SOURCESEQNO    | Source serial number |
|                                  | Message              | --             | KNBC00030-I          |
| Extended attribute (Common Info) | Event level          | SEVERITY       | Information          |
|                                  | Product name         | PRODUCT_NAME   | /HITACHI/JP1/JPCCS2  |
|                                  | Object type          | OBJECT_TYPE    | SERVICE              |
|                                  | Object name          | OBJECT_NAME    | IMBASE               |
|                                  | Occurrence           | OCCURRENCE     | NOTICE               |

Legend: --: None

#1

This JP1 event is tied to the manager node. In a configuration with more than one manager, only the directly connected manager node is associated with it.

#2

The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

## (8) JP1 Events Issue When Deletion of agent is detected

Table 3–10: List of attributes for JP1 events that are issued when deletion for agent is detected

| Classification   | Item              | Attribute name | Description                              |
|------------------|-------------------|----------------|------------------------------------------|
| Basic attributes | Event ID          | --             | The default Value is the "00007631" #1.  |
|                  | Serial number     | SEQNO          | Serial number                            |
|                  | Source process ID | PROCESSID      | 0                                        |
|                  | Registered time   | TIME           | Time of registration                     |
|                  | Arrival time      | ARRIVEDTIME    | Time of arrival                          |
|                  | Source user ID    | USERID         | For -1 to 65,535#2                       |
|                  | Source group ID   | GROUPLD        | For -1 to 65,535#2                       |
|                  | Source user name  | USERNAME       | In Windows: SYSTEM<br>In UNIX: root      |
|                  | Source group name | GROUPNAME      | In Windows: NULL string<br>In UNIX: root |

| Classification                          | Item                      | Attribute name | Description               |
|-----------------------------------------|---------------------------|----------------|---------------------------|
|                                         | Event-issuing server name | SOURCESERVER   | Event-issuing server name |
|                                         | Source serial number      | SOURCESEQNO    | Source serial number      |
|                                         | Message                   | --             | KNBC00031-I               |
| Extended attribute (Common Information) | Event level               | SEVERITY       | Information               |
|                                         | Product name              | PRODUCT_NAME   | /HITACHI/JP1/JPCCS2       |
|                                         | Object type               | OBJECT_TYPE    | SERVICE                   |
|                                         | Object name               | OBJECT_NAME    | IMBASE                    |
|                                         | Occurrence                | OCCURRENCE     | NOTICE                    |

Legend: --: None

#1

This JP1 event is tied to the manager node. In a configuration with more than one manager, only the directly connected manager node is associated with it.

#2

The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

## (9) JP1 Events Issues when Updating agent Info is Detected

Table 3–11: List of attributes for JP1 events issue when updating agent data is detected

| Classification   | Item                      | Attribute name | Description                              |
|------------------|---------------------------|----------------|------------------------------------------|
| Basic attributes | Event ID                  | --             | The default Value is the "00007632" #1.  |
|                  | Serial number             | SEQNO          | Serial number                            |
|                  | Source process ID         | PROCESSID      | 0                                        |
|                  | Registered time           | TIME           | Time of registration                     |
|                  | Arrival time              | ARRIVEDTIME    | Time of arrival                          |

#1

This JP1 event is tied to the manager node. In a configuration with more than one manager, only the directly connected manager node is associated with it.

#2

The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

## (10) JP1 Events to be Issued on a Successful Deletion of Defined Files

Table 3–12: List of attributes for JP1 events that are issued when Deletion of File is successful

| Classification   | Item                      | Attribute name | Description                              |
|------------------|---------------------------|----------------|------------------------------------------|
| Basic attributes | Event ID                  | --             | The default Value is "00007640".         |
|                  | Serial number             | SEQNO          | Serial number                            |
|                  | Source process ID         | PROCESSID      | 0                                        |
|                  | Registered time           | TIME           | Time of registration                     |

The substitute user ID and substitute group ID specified in the event server settings file are set. If they are not specified, -1 is set.

# 4

## User-created Plug-ins

In JP1/IM - Manager (Intelligent Integrated Management Base), the users can perform some operations with their own plug-ins. This chapter describes the user-created plug-ins.

## 4.1 What a user can do with the user-created plug-in

The user can create a plug-in and retrieve information from the management tool of a linked product, to manage it with the Intelligent Integrated Management Base. The following figure shows the operations provided by the user-created plug-in.

Figure 4–1: Operations provided by the user-created plug-in

The following describes the flow using numbered steps (the numbers correspond to the numbers in the figure).

1. Assign IDs to targets managed by management tool A and collect data.
2. Collect and configure relation information between D and G.
3. Retrieve the tree SID of the IM management node.
4. Retrieve the data on management targets.
5. Associate a JP1 event with the management target to manage the status of the target#.
6. Obtain the URL of a linked product from JP1 event information to open the window of the linked product.

#: As an assumption, the management target must issue a JP1 event to manage its status.

### 4.1.1 Format of the user-created plug-in

The user-created plug-in is written in JavaScript and provides its functionality in the CommonJS module format. The following example shows the format of a user-created plug-in and how to write a method called when configuration information is retrieved.

Format

```
module.exports = {  
    operations-of-the-user-created-plug-in  
};
```

## Example

```
module.exports = {
    // Operations performed when configuration information is retrieved
    __configurationGet : function(args) {
        // Determine if the configuration collection should be processed with args.component
        if (args.component !== "/HITACHI/JP1/PP/CONFINFO") {
            return;
        }
        // If yes:
        // When args.data contains configuration information in JSON format, pass it as it is
        args.setResult(args.data);
    },
};
```

The following shows the rules for writing the user-created plug-in:

- Plug-in file name: *product-name.js*  
Example: jplpfm.js, jplajs.js
- Encoding: ASCII
- Language: English  
Comments must also be in English.
- Supported line feed code  
CR, LF, CR+LF

### Important

When a user creates a new method, the name of the method must not start with an underscore.

## 4.2 Setting up and considering the management target

Before adding a new target managed by JP1/IM - Manager (Intelligent Integrated Management Base), you need to set up and consider the management target.

### 4.2.1 Adding a host

If you add a management target as a managed host, you need to add an additional host setting to the following definition files:

- System node definition file (`imdd_systemnode.conf`)
- Target host definition file for configuration collection (`imdd_target_host.conf`)

For details about the definition files, see *System node definition file (`imdd_systemnode.conf`)* and *Target host definition file for configuration collection (`imdd_target_host.conf`)* in *Chapter 2. Definition Files*.

### 4.2.2 Considering the SID

When adding the management target, you need to assign an SID that represents the target. For details on the SID, see *7.1 SID*.

In this section, the following hosts are used as examples of the management targets for description:

- Host A where management tool A is running
- Agent host B managed by management tool A

Specify SIDs as follows:

- Class of the SID for indicating any SID related to management tool A: `_ToolA-M_`
- Class of the SID for indicating a host: Use the reserved word `_HOST_`
- SID of the host where management tool A is running: `_ToolA-M_hostA/_HOST_hostA`
- Class of the SID for any agent host managed by host A: `_ToolA-A_`
- SID that represents host B: `_ToolA-M_hostA/_ToolA-A_hostB/_HOST_hostB`

#### Important

Define the class of an SID with a given string starting with an underscore (`_`) and ending with an underscore (`_`). In addition, `_JP1`, a string starting with `_HITACHI`, and another string starting with `_ROOT_`, `_SYSTEM_`, `_CATEGORY_`, `_SUBCATEGORY_`, or `_OBJECT_` are not available. The class is case insensitive.

If you use a JP1 event to manage the status of a monitoring target, you need to create the SID of the management node from the data of the JP1 event. Check to see if you can create the SID from the data of the JP1 event before considering the SID.

## 4.2.3 Considering data labeled "value" of the SID

You can add additional information labeled value to the assigned SID. JP1/IM - Manager (Intelligent Integrated Management Base) provides the variables listed in the following table.

Table 4–1: Variable names and their values

| No. | Variable name | Value                                                                                                                                                                                                                                                                                                                                                                        |
|-----|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | component     | Specifies the name of the product that manages the management target and the name of the product's component. SYSTEM, DEFAULT, and a string starting with HITACHI are reserved words and therefore cannot be specified.<br>You can use ASCII numbers, uppercase alphabetic letters, and a forward slash (/). The value must be within 240 bytes.<br>Example<br>/VENDOR/TOOLA |
| 2   | category#     | Specifies the category information that corresponds to each component (categoryId).                                                                                                                                                                                                                                                                                          |
| 3   | subCategory   | Specifies the subcategory, such as a product name. This value can be up to 255 characters (any characters except control characters).                                                                                                                                                                                                                                        |
| 4   | label         | Specifies the name after a change, if the component name displayed in the tree is to be changed.                                                                                                                                                                                                                                                                             |
| 5   | methods       | Specifies the names of plug-in functions, in array format, that are executable through the plug-in processing execution REST API for the applicable component.                                                                                                                                                                                                               |

#

Specify the categoryId defined in the category name definition file for IM management nodes (imdd\_category\_name.conf) by using up to 255 half-width alphanumeric characters.

If you specify a category other than a standard category, add a definition to the category name definition file for IM management nodes. For details on the definition file, see [Category name definition file for IM management nodes \(imdd\\_category\\_name.conf\)](#) in *Chapter 2. Definition Files*.

The following table lists category IDs that the category variable can accept.

Table 4–2: Category IDs that the category variable can accept

| No. | Category display name           | Category ID to be specified |
|-----|---------------------------------|-----------------------------|
| 1   | Job                             | job                         |
| 2   | Service Response                | serviceResponse             |
| 3   | Enterprise                      | enterprise                  |
| 4   | Transaction Processing          | transactionProcessing       |
| 5   | Application Server              | applicationServer           |
| 6   | Database                        | database                    |
| 7   | Platform                        | platform                    |
| 8   | Service                         | service                     |
| 9   | Virtual Machine                 | virtualMachine              |
| 10  | Management Applications         | managementApplications      |
| 11  | Other Applications              | otherApplications           |
| 12  | Arbitrary category display name | Arbitrary category          |

The following shows an example in which up is added as categoryId and User Program as categoryName.

```
{
  "meta":{
    "version":"1"
  },
  "categoryData":[
    {"categoryId":"job","categoryName":"Job"},
    {"categoryId":"serviceResponse","categoryName":"Service Response"},
    {"categoryId":"enterprise","categoryName":"Enterprise"},
    {"categoryId":"transactionProcessing","categoryName":"Transaction Processing"},
    {"categoryId":"applicationServer","categoryName":"Application Server"},
    {"categoryId":"database","categoryName":"Database"},
    {"categoryId":"platform","categoryName":"OS"},
    {"categoryId":"service","categoryName":"Service"},
    {"categoryId":"virtualMachine","categoryName":"Virtual Machine"},
    {"categoryId":"otherApplications","categoryName":"Other Applications"},
    {"categoryId":"up","categoryName":"User Program"}
  ]
}
```

## 4.3 Retrieving information from the management target

You can retrieve information from a management target in one of the following ways:

- Adapter command
- REST API

The adapter command is executed only once.

The creation of an adapter command is mandatory.

### 4.3.1 Collecting information with the adapter command

If you create a user-created plug-in and retrieve information from a management target in JP1/IM - Manager (Intelligent Integrated Management Base), you need an adapter command together with the plug-in. You execute the adapter command only once. You execute the adapter command several times and cannot acquire information. In addition, the adapter command has a one-to-one relationship with the user-created plug-in.

The adapter command communicates with the Intelligent Integrated Management Base via the standard input and output. When started from the Intelligent Integrated Management Base, the adapter command sends a response to the Intelligent Integrated Management Base via the standard output.

#### (1) Return values

The adapter command gives back the summary of an operation result as a return value.

Table 4–3: Return values of the adapter command

| No. | Return value | Description                                                                                                          |
|-----|--------------|----------------------------------------------------------------------------------------------------------------------|
| 1   | 0            | Successful completion                                                                                                |
| 2   | 1 to 49      | These values are assigned to an error when a warning occurs. (For example, a failure to collect part of information) |
| 3   | 50 to 99     | These values are assigned to a temporary error of the operation that can be retried.                                 |
| 4   | 100 to 149   | Invalid environment (such as an incorrect version)                                                                   |
| 5   | 150 to 199   | Program error                                                                                                        |

You can also add a return value specific to the adapter command within the range of the return values. The details of an error at runtime of the adapter command must be returned separately via the standard error output.

#### (2) Execution directory

The directory where the adapter commands is located as the execution directory.

#### (3) Input/output

Arguments, the standard input, the standard output, and the standard error output are used for data communication between the adapter command and the Intelligent Integrated Management Base.

The standard input and standard output of the adapter command is made up of *common header* and *data body*. The *data body* contains the information passed from the adapter command to the Intelligent Integrated Management Base.

The format is as follows:

```
Common header<Line feed code (<CR><LF> or <LF>)>Data body
```

The structure of the header is shown below. The header is expressed in CSV format.

```
protocol-name,protocol-version,character-code,program-product-name
```

The following table lists the details of the header:

| No. | Name                        | Data type | Value to be specified                                                                                                                                                                                                                              |
|-----|-----------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <i>protocol-name</i>        | string    | JBSPGCMMD                                                                                                                                                                                                                                          |
| 2   | <i>protocol-version</i>     |           | Specify the same version as the <i>version of the adapter command settings file</i> <sup>#</sup> .<br>Example<br>12000000                                                                                                                          |
| 3   | <i>character-code</i>       |           | Specify one of the following character codes based on the execution environment of the adapter command: <ul style="list-style-type: none"><li>• 8859_1</li><li>• SJIS</li><li>• MS932</li><li>• EUCJIS</li><li>• UTF-8</li><li>• GB18030</li></ul> |
| 4   | <i>program-product-name</i> |           | Specify the same value as the <i>component identifier</i> <sup>#</sup> .                                                                                                                                                                           |

#

For details, see [7.3.2 Adapter command settings file](#).

If an error occurs during execution of the adapter command, the details are printed to the standard error output. Configure the details to be printed in ASCII characters.

## (4) Notes

- The following commands are not available as the adapter command:
  - Command that requires a sub-entry command (interactive operation)
  - Command that involves escape sequences and control codes
  - Command that opens a window at the location where the command is executed
  - Command that does not end, such as a daemon
- The user may start more than one instance of the adapter command at the same time. If starting two or more instances of the adapter command simultaneously is not allowed, add an exclusive operation of its own to the command so that it returns a busy response when the second instance is started.
- Data cannot be sent and received simultaneously via the standard input and output. The adapter command that receives a request via the standard input must start sending response data after receiving all the request data.
- The adapter command is executed under the following permissions:

- In Windows: SYSTEM
- In UNIX: root
- A timeout period is set on the adapter command. Thus, the response must be returned before the command times out. The timeout period is 60 minutes.

## (5) Adapter command settings file

An adapter command settings file is used to specify the name of the file for the adapter command. The naming rule is as follows:

```
name-of-the-component-specified-for-Adapter_SID.conf
```

### Example

When the *name-of-the-component-specified-for-Adapter\_SID* is /VENDOR/TOOLA:

```
Adapter_VENDOR_TOOLA.conf
```

The adapter command settings file is located at:

In Windows:

```
JPI/Base-installation-folder\plugin\conf
```

In UNIX:

```
/opt/jplbase/plugin/conf
```

The table below lists the setting items of the adapter command settings file. Use a tab or white space character to separate a label and its value.

Table 4–4: Setting items of the adapter command settings file

| No. | Item                                         | Label         | Value to be specified                                                                                                                                              |
|-----|----------------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Version of the adapter command settings file | fileversion   | 12000000                                                                                                                                                           |
| 2   | Path to the adapter command                  | cmdpath       | Specify the absolute path to the adapter command, including the command name. You do not have to enclose the path with double quotation marks or other characters. |
| 3   | Product that links with the adapter command  | upperpp       | /HITACHI/JP1/IM/DD                                                                                                                                                 |
| 4   | Type of the adapter command                  | componenttype | JDD_CONFINFO                                                                                                                                                       |

The following shows a setting example of the adapter command settings file:

```
fileversion      12000000
cmdpath          C:\Program Files (x86)\Hitachi\jplpc\bin\jplgetconfinfo.exe
upperpp          /HITACHI/JP1/IM/DD
componenttype    JDD_CONFINFO
```

### ! Important

- A single line can contain a maximum of 4,096 characters.

- If there is more than one label with the same name, an error occurs.
- If the required label is not specified, an error occurs.
- If even a single error exists in the file, the file is no longer valid.
- The file is terminated with the line feed character.
- The file can contain ASCII characters only.
- When you specify a label, a white space or tab character is not allowed at the beginning of the row.
- Any row containing white space or tab characters only is ignored.

### 4.3.2 Retrieving information with the REST API

If you use the `jp1Imdd.callRest` method in the `__configurationGet` method of a user-created plug-in, you can execute any REST API. For details on the `jp1Imdd.callRest` method, see [4.5.1 \*jp1Imdd.callRest\*](#).

## 4.4 Methods implemented in the plug-in

You implement the user-created plug-in that processes only what it can deal with by referring to the parameter values. If something is beyond the operation of the plug-in, it should return at once. In this case, avoid calling a method, such as the `setError` method.

### 4.4.1 Format of methods you can implement

The following table lists and describes the format of methods that you can implement in the user-created plug-in.

Table 4–5: Format of the method to be provided

| No. | Item          | Name              | Description                                                                                                                                                                                                           |
|-----|---------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Method name   | --                | The name of each method                                                                                                                                                                                               |
| 2   | Parameters    | <code>args</code> | See the description of each method.<br><br>Use the <code>args.setError</code> method, instead of an exception, to notify an error. For details, see <a href="#">4.4.4(1) <code>__configurationGet</code> method</a> . |
| 3   | Return values | None              |                                                                                                                                                                                                                       |
| 4   | Exception     | None              |                                                                                                                                                                                                                       |

### 4.4.2 Implementation conventions of user-created plug-ins

The following shows the implementation conventions of user-created plug-ins:

- If JP1/IM receives a request from a user or a system that uses REST APIs, it always calls the method that corresponds to the request without being aware of the plug-ins.
- The plug-in refers to parameter information of methods and processes only those that can be processed by it. If the plug-in cannot process the methods, use `return` immediately without calling the `setError` method or logging the error.  
This is because if you call the `setError` method without using `return` immediately, the next plug-in will not be called and the call operation will exit.
- Whether a plug-in can be processed is basically determined by the `sid` value of the parameter. If you need to determine it based on information other than `sid`, see each method.

### 4.4.3 Language conventions of user-created plug-ins

If you pass `lang` (language information) to a method of a user-created plug-in, the language setting of the WWW browser is passed to it when you execute the method from the window of JP1/IM, and the value specified in the `Accept-Language` header of the HTTP request is passed to it when you execute the method from a REST API.

Make the user-created plug-ins work in Japanese mode when `ja` or `ja-JP` is specified or in English mode if `en` is specified.

Define how each user-created plug-in works if a value other than these values is specified. If `lang` is omitted or any undefined value is specified, make the plug-ins work as if `en` is specified.

## 4.4.4 List of methods

The table below lists and describes the methods to be implemented in the user-created plug-in.

You do not have to implement all the methods. Choose the methods you need for each product and implement them. For details about the plug-in methods provided by different products, see the respective manuals supplied with the products.

Table 4–6: List of methods implemented in the user-created plug-in

| No. | Category                         | Method name                                | Description                                                                                     | Number in 4.1#2 |
|-----|----------------------------------|--------------------------------------------|-------------------------------------------------------------------------------------------------|-----------------|
| 1   | Get configuration information    | <code>__configurationGet</code>            | The method to collect the configuration information                                             | 1               |
| 2   |                                  | <code>__configurationGetAdapterless</code> | Method to retrieve configuration information (when the adapter command has not been set up)     |                 |
| 3   |                                  | <code>__createTreeNode</code>              | The method to collect tree information                                                          |                 |
| 4   | Event                            | <code>__eventGet</code>                    | The method to process JP1 events                                                                | 5               |
| 5   |                                  | <code>__transformEvent</code>              | This method converts event data (generated by an external system) to JP1 events.                |                 |
| 6   | Get relation information         | <code>__createLink</code>                  | The method to generate a relation between collected configurations.                             | 2               |
| 7   |                                  | <code>__linkValueGet</code>                | The method to collect the details of link information                                           |                 |
| 8   |                                  | <code>__simtLoad</code>                    | A method that collects related information needed when IM management node is loaded.            |                 |
| 9   | Get trend information            | <code>__metricListGet</code>               | The method to get the list of metrics for time-series data that can be collected                | 3               |
| 10  |                                  | <code>__timeSeriesDataGet</code>           | The method to collect time-series data                                                          |                 |
| 11  | Get url information              | <code>__urlGet</code>                      | The method to get the URL for starting a monitor                                                | 6               |
| 12  | Any method created by the user#1 | Any method created by the user#1           | An arbitrary method created by the user. Avoid the method name starting with an underscore (_). | 3               |

#1

The arbitrary method created by the user is executed via the plug-in processing execution API (`im_api_v1_actions`). For details on the plug-in processing execution API (`im_api_v1_actions`), see [5.7.1 Plug-in processing execution](#).

#2

The numbers in this column correspond to the numbers in [4.1 What a user can do with the user-created plug-in](#).

### (1) `__configurationGet` method

#### Description

The method returns the configuration information of each product in JSON format. When host name is written to target host definition file for configuration collection (`imdd_target_host.conf`), in the Intelligent Integrated Management Base, call this method only when checking the return value of the adapter command after it is called and finding the value is 0.

- If the configuration information is collected successfully  
In the `__configurationGet` method, call the `args.setResult` (configuration information in JSON format) method.

- If the method fails to collect the configuration information

Call the `args.setError (error message)` method, instead of the `args.setResult` method.

In the `__configurationGet` method, either the `args.setResult` or `args.setError` method must be called if the `__configurationGet` method can process the component.

The `__configurationGet` method is called within the `jddcreatetree` command that creates the system management tree of the Intelligent Integrated Management Base.

Each user-created plug-in should refer to the value of `args.component` to determine if the plug-in can deal with the component.

#### Parameters

The following table lists and describes the parameters of the `__configurationGet` method.

**Table 4–7: Parameters of the `__configurationGet` method**

| No. | Member                                 | Description                                                                                                                                                                               | Remarks                                                                         |
|-----|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| 1   | <code>hostname</code>                  | Name of the host from which the configuration information is collected                                                                                                                    | None                                                                            |
| 2   | <code>component</code>                 | Name of the component managing the configuration information                                                                                                                              | "/HITACHI/JP1/PPM/CONFINFO"                                                     |
| 3   | <code>data</code>                      | Execution result of the adapter command.<br>It is a string converted into UTF-8 format, based on the character code in the header information.<br>The header information is not included. | None                                                                            |
| 4   | <code>jplUserName</code>               | JP1 user name                                                                                                                                                                             | The user has the administrator permissions for each product.                    |
| 5   | <code>jplToken</code>                  | JP1 token for <code>jplUserName</code>                                                                                                                                                    | The JP1 token is BASE64 encoded.                                                |
| 6   | <code>protocolName</code>              | Protocol name                                                                                                                                                                             | The header information contained in the execution result of the adapter command |
| 7   | <code>protocolVersion</code>           | Protocol version                                                                                                                                                                          | The header information contained in the execution result of the adapter command |
| 8   | <code>codeset</code>                   | Character code                                                                                                                                                                            | The header information contained in the execution result of the adapter command |
| 9   | <code>productName</code>               | Product name                                                                                                                                                                              | The header information contained in the execution result of the adapter command |
| 10  | <code>setResult (String json)</code>   | The method to set the configuration information in JSON format                                                                                                                            | None                                                                            |
| 11  | <code>setError (String message)</code> | The method for error notification.<br>It sets an error message.                                                                                                                           |                                                                                 |
| 12  | <code>stderr</code>                    | It stores the value output by the adapter command to the standard error output.                                                                                                           |                                                                                 |

#### Note

You need to assign an SID with the value information added for each component to the configuration information that is set for `setResult`. For details on the SID, see [7.1 SID](#).

#### List of configuration information to be returned

The following describes the list of configuration information returned by the `__configurationGet` method.

## Formats

```
{
  "meta":{
    "timestamp":"created-time(ISO8601-formatted-UTC-time)",
    "objectRoot":[
      {
        "type":"object-root-node-type",
        "defaultSystem":
        {
          "name":"name-of-the-structured-identifier-of-the-default-s
ystem-node",
          "label":"display-name-of-the-default-system-node"
        }
      },...
    ]
  },
  "simtData":[
    {"sid":"<SID>","value":{"structured identifier"}},
    ...
  ]
}
```

## Describe

The following table lists and describes what is contained in the list of obtained infrastructures.

Table 4–8: Description in the list of obtained infrastructures

| No. | Item          | Data types | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----|---------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | meta          | Object     | An object that stores file information                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2   | timestamp     | string     | Returns the date and time of file creation as the UTC time in ISO8601 format.<br>This attribute cannot be omitted.<br>The time is the server time of JP1/IM - Manager.                                                                                                                                                                                                                                                                                |
| 3   | objectRoot    | array      | An array that stores the object root node type and the default system node information.<br>This attribute can be omitted.                                                                                                                                                                                                                                                                                                                             |
| 4   | type          | string     | Indicates the object root node type (such as a network device (NETWORKDEVICE) or storage (STORAGE)) placed under the root node of the tree and under the system node.<br>The host (HOST) does not have to be specified. Make sure that it is placed under the root node of the tree and under the system node.<br>This attribute can be omitted. If it is omitted, only the host is placed under the root node of the tree and under the system node. |
| 5   | defaultSystem | Object     | Specify the attribute if you create a default system node whose parent node is the object root node.<br>If this attribute is omitted, the default tree node of the object root node specified in type is placed directly under AllSystems.                                                                                                                                                                                                            |
| 6   | name          | string     | Specifies the name of the configuration information SID for the default system node.<br>If this attribute is omitted, the object root node type is set as the SID name of configuration information.                                                                                                                                                                                                                                                  |
| 7   | label         | string     | Specifies the label of the default system node.<br>If this attribute is omitted, the label attribute is not set for the additional information of the default system node.                                                                                                                                                                                                                                                                            |
| 8   | simtData      | array      | An array of configuration information                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 9   | sid           | string     | Indicates the configuration information SID.                                                                                                                                                                                                                                                                                                                                                                                                          |

| No. | Item  | Data types | Description                       |
|-----|-------|------------|-----------------------------------|
| 10  | value | Object     | Indicates a structured identifier |

#### Example

For details on the information the `__configurationGet` method retrieves from each product, see [7.1.4 Information retrieved from each product](#).

#### Impact of configuration information set by `setResult`

The following table lists and describes the functions that are affected by the configuration information set by `setResult` and its impact.

**Table 4–9: List of affected functions**

| No. | Function                                                | Impact                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | System status monitoring                                | <ul style="list-style-type: none"> <li>The IM management node acquisition function outputs the set configuration information as an IM management node file.</li> <li>The IM management node tree generation function<sup>#</sup> uses the configuration information to generate a tree and outputs it as an IM management node tree file.</li> <li>The <code>__eventGet</code> method uses the SID of the configuration information. With the <code>__eventGet</code> method, a JP1 event is mapped with an IM management node.</li> </ul>                                                                                                                                |
| 2   | Integrated monitoring of systems by IM management nodes | <p><code>__createLink</code> or the IM management node link definition file (<code>imdd_nodeLink_def.conf</code>) uses the SID of the configuration information.</p> <p>Workflows are displayed according to IM management node links with type of <code>rootJobnetExecutionOrder</code> (root jobnet execution order).</p>                                                                                                                                                                                                                                                                                                                                               |
| 3   | Custom UI display                                       | A custom UI window is displayed according to the SID of the configuration information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 4   | Related node display                                    | <code>__createLink</code> or the IM management node link definition file ( <code>imdd_nodeLink_def.conf</code> ) uses the SID of the configuration information. Related nodes are displayed according to IM management node links.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 5   | IM management node property display                     | The information specified in <code>property</code> of the additional information ( <code>value</code> ) of the configuration information is displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 6   | Startup of a linked product window                      | The window of a linked product is opened for the IM management node in which <code>__urlGet</code> is specified in methods of the additional information ( <code>value</code> ) of the configuration information.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 7   | Trend information display                               | Trend information on the specified metric is displayed for the IM management node in which <code>__metricListGet</code> and <code>__timeSeriesDataGet</code> are specified in methods of the additional information ( <code>value</code> ) of the configuration information.                                                                                                                                                                                                                                                                                                                                                                                              |
| 8   | Managing Trend Data by IM management node               | <p>Refer to the <code>jp1im_TrendData_labels</code> of the configuration information grant information (<code>value</code>), and specify the value of replacement string "<code>\$jp1im_TrendData_labels</code>" specified in PromQL expression in the argument <code>promQLQuery</code> of <code>jp1TrendDataService.getTrendData</code> method.</p> <p>If the <code>jp1im_TrendData_labels</code> of the configuration information is not specified, trend data related to the applicable managed node cannot be acquired.</p> <p>For details of <code>jp1TrendDataService.getTrendData</code> method, see <a href="#">4.5.17 jp1TrendDataService.getTrendData</a>.</p> |

#

For details on the IM management node tree generation function, see [7.4 IM management node tree generation function](#).

## (2) \_\_configurationGetAdapterless method

### Description

Similar to the \_\_configurationGetAdapterless method, this method returns the configuration of the application in JSON format. Implement and use this method if you cannot implement adapter commands, such as monitoring SaaS. Intelligent Integrated Management Base invokes this method if you do not write host name in target host definition file for configuration collection (imdd\_target\_host.conf) only.

If you want to implement this method on each user-created plug-in, refer to value of args.component to determine if it can be processed.

The specific environment information required to implement this method (for example, information related to authentication when monitoring SaaS) is described in file defined in user-created plug-in. For details, see [4.6.1 Definition files used by user-created plug-ins](#).

### Parameters

The following table lists and describes the parameters of the \_\_configurationGetAdapterless method.

Table 4–10: Parameters of the \_\_configurationGetAdapterless method

| No. | Member                   | Description                                                        | Remarks                                                                                                                    |
|-----|--------------------------|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| 1   | component                | Component name from which the configuration information is managed | "/HITACHI/JP1/PFM/" + Product name specified in product of the configuration target definition file (imm_target_host.conf) |
| 2   | jp1UserName              | JP1 user name                                                      | User with administrator privileges for each product                                                                        |
| 3   | jp1Token                 | jp1UserName JP1 token                                              | JP1 tokens are BASE64 encoded                                                                                              |
| 4   | setResult(String json)   | Method that sets JSON form of the configuration                    | None                                                                                                                       |
| 5   | setError(String message) | Methods for Error Notifications<br>Sets an error message.          |                                                                                                                            |

### Note

For the configuration information to be specified to setResult, SID must be added with value information for each component. For details of SID, see [7.1 SID](#).

- When acquisition of configuration information ends normally  
Invoke the args.setResult in \_\_configurationGetAdapterless method (JSON format configuration information).
- When acquisition of configuration information fails  
Call args.setError (error message) method instead of args.setResult method.

In the \_\_configurationGetAdapterless method, if the component can be processed by itself, be sure to call either args.setResult method or args.setError method.

The \_\_configurationGetAdapterless method is called in jddcreatetree command that creates Intelligent Integrated Management Base system-managed tree.

### List of configuration information to be returned

The format of retrieving the list of configuration information returned by the \_\_configurationGetAdapterless method, the description, and the effect of the configuration information set by setResult are the same as those of the \_\_configurationGet method.

When to use the `__configurationGet` method properly

The main differences between the `__configurationGet` and `__configurationGetAdapterless` methods are listed below.

Table 4–11: `__configurationGet` and `__configurationGetAdapterless` methods compared

| Method name                                | Configuration acquisition target definition<br>Description in file | Method for obtaining unique environment information     | Remarks              |
|--------------------------------------------|--------------------------------------------------------------------|---------------------------------------------------------|----------------------|
| <code>__configurationGet</code>            | Products and host name                                             | Adapter command or user-created plug-in definition file | JP1/Base is required |
| <code>__configurationGetAdapterless</code> | Product only                                                       | User-created plug-in definition file                    | None                 |

Therefore, the `__configurationGet` method and the `__configurationGetAdapterless` method are used differently as shown in the tables below.

Table 4–12: Use of the `__configurationGet` and `__configurationGetAdapterless` methods

| Usage method name                          | Use case                                                                                                                                                                                 |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>__configurationGet</code>            | <ul style="list-style-type: none"><li>If you do not want to include environmental data in product plugin definition file (for security or other reasons)</li></ul>                       |
| <code>__configurationGetAdapterless</code> | <ul style="list-style-type: none"><li>If you cannot install JP1/Base</li><li>When it is difficult to implement adapter commands (when you do not need to use adapter commands)</li></ul> |

### (3) `__createTreeNode` method

#### Description

The method collects the tree SID that corresponds to `simtData` in the input information together with additional information, and returns them in JSON format.

If a user-created plug-in implements the `__createTreeNode` method, the default tree of JP1/IM can be customized. For details on the default tree, see [7.4.2 Node generation function](#).

The user-created plug-in generates a tree node object and sets it with `setResult` if the tree SID of `simtData` is the target of the tree node to be customized. If `simtData` objects have identical values in both the object type and name of the target, they will be the same node in the tree. Therefore, configure `simtData` objects that have identical values in both the object type and name to return the same tree SID.

If you do not customize the parent node of the tree node to be customized, use the `treeNodeCreator` object to get the tree SID of the parent node portion and use it as a part of the tree SID.

- If the tree SID and additional information can be retrieved successfully  
Call the `args.setResult` (tree SID in JSON format) method within the `__createTreeNode` method.
- If the tree SID and additional information cannot be retrieved  
Call the `args.setError` (error message) method, not the `args.setResult` method.

If the `__createTreeNode` method itself can process `SimtData`, make sure to call either the `args.setResult` method or `args.setError` method within the `__createTreeNode` method.

The `__createTreeNode` method is called in the `jddcreatetree` command that creates a system management tree for the Intelligent Integrated Management Base.

#### Parameters

The following table lists and describes the parameters of the `__createTreeNode` method.

Table 4–13: Parameters of the \_\_createTreeNode method

| No. | Member                       | Description                                                                                                                                                                      | Remarks |
|-----|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 1   | jplUserName                  | The JP1 user name                                                                                                                                                                | None    |
| 2   | jplToken                     | A JP1 authentication token that corresponds to jplUserName                                                                                                                       |         |
| 3   | simtData                     | SimtData of which you want to get the tree SID                                                                                                                                   |         |
| 4   | treeNodeCreator              | An object that provides the functions to manage information of created nodes and create a default tree.<br>For details, see <a href="#">4.4.4(3)(a) treeNodeCreator object</a> . |         |
| 5   | setResult<br>(String json)   | The method to set the retrieved tree SID and additional information in JSON format                                                                                               |         |
| 6   | setError<br>(String message) | The method for error notification.<br>It sets an error message.                                                                                                                  |         |

Format of the tree SID and additional information to be returned

The following describes the format of the tree SID and additional information returned by the \_\_createTreeNode method.

#### Formats

```
{
  "meta":{
    "componentName":"name-of-the-component-from-which-tree-informat
ion-is-retrieved"
  },
  "simtData":[
    {"sid":"tree-SID","value":{"structured-identifier}},
    ...
  ]
}
```

#### Describe

The following table lists and describes the items of the retrieved tree SID and additional information.

Table 4–14: Items of the retrieved tree SID and additional information

| No. | Item          | Data types | Description                                                                       |
|-----|---------------|------------|-----------------------------------------------------------------------------------|
| 1   | meta          | Object     | Indicates meta information.                                                       |
| 2   | componentName | string     | Indicates the name of the component from which the tree information is retrieved. |
| 3   | simtData      | Object     | Indicates a simtData                                                              |
| 4   | sid           | string     | Indicates a tree SID                                                              |
| 5   | value         | Object     | Indicates a structured identifier                                                 |

#### Example

The following shows an example of retrieving information with the \_\_createTreeNode method.

```
{
  "meta":{
    "componentName":"/HITACbHI/JP1/OA/CONFINFO"
  },
  "simtData":[
```

```

    {
      "sid": "_ROOT_AllSystems/_HOST_host1/_CATEGORY_job
/_SUBCATEGORY_JP1%2FAJS3%20-%20Manager/_OBJECT_AJSROOT1",
      "value":
        {
          "target": ["_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_AJSROOT1"
],
          "label": "AJSROOT1"}
        }

#### Impact of IM management node tree information set by setResult

The following table lists and describes the function that is affected by the IM management node tree information set by setResult and its impact.

**Table 4–15: List of affected functions**

| No. | Function                 | Impact                                                                                                                                                                                  |
|-----|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | System status monitoring | IM management node information is merged with tree information generated by the IM management node tree generation function <sup>#</sup> and output as an IM management node tree file. |

#

For details on the IM management node tree generation function, see [7.4 IM management node tree generation function](#).

#### (a) treeNodeCreator object

The treeNodeCreator object provides the getObjectRootTreeSID, getHostNameDef, and getCategoryName methods.

#### (b) getObjectRootTreeSID method

The getObjectRootTreeSID method returns the tree SID that corresponds to target (SID) specified in the parameter. Use this method when you do not customize the parent node of an object node, and then use the return value as a part of the tree SID of the object node.

##### Parameters

The following table lists and describes the parameters of the getObjectRootTreeSID method.

**Table 4–16: Parameters of the getObjectRootTreeSID method**

| No. | Item       | Data types | Description                                                                                                               |
|-----|------------|------------|---------------------------------------------------------------------------------------------------------------------------|
| 1   | target     | string     | Configuration information SID for the object root node corresponding to the parent node of the tree node to be customized |
| 2   | objectRoot | Object[]   | Object root node information<br>Use the format below.<br>[{"type": "object-root-node-type"}, , , }, # ...]                |

#

You can specify information in the object in the same format as meta.objectRoot of configuration information that is retrieved by the \_\_configurationGet method. For details, see [4.4.4\(1\) \\_\\_configurationGet method](#).

## Return values

The method returns the tree SID that corresponds to `target`. The return values vary depending on how the tree node is generated when the `getObjectRootTreeSID` method is called.

Table 4–17: Return values of the `getObjectRootTreeSID` method

| No. | How the tree node is generated              | Return values                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | If the tree node has already been generated | The method returns the generated tree SID that corresponds to <code>target</code> .                                                                                                                                                                                                                                                                                                                                                         |
| 2   | If the tree node has not been generated     | <p>The method analyzes the content of <code>target</code> and generates the tree SID that is based on the definitions in the system node definition file (<code>imdd_systemnode.conf</code>) and the host name definition file (<code>imdd_host_name.conf</code>).</p> <p>If the content does not match the definition in the system node definition file (<code>imdd_systemnode.conf</code>), the method returns the default tree SID.</p> |

For details about the system node definition file, see [System node definition file \(`imdd\_systemnode.conf`\)](#) in *Chapter 2. Definition Files*.

## (c) `getHostNameDef` method

The `getHostNameDef` method returns the host name definition that corresponds to `hostName` specified in the parameter, according to the host name definition file (`imdd_host_name.conf`). Use this method if you customize the tree for the `HOST` node, and then use the return values as a name and label of the tree SID of the `HOST` node.

### Parameters

The following table lists and describes the parameters of the `getHostNameDef` method.

Table 4–18: Parameters of the `getHostNameDef` method

| No. | Item                  | Data types | Description                           |
|-----|-----------------------|------------|---------------------------------------|
| 1   | <code>hostName</code> | string     | Specifies the host name (alias name). |

## Return values

The `getHostNameDef` method returns the following value according to the definition in the host name definition file (`imdd_host_name.conf`):

```
{ "hostName": "value-in-the-definition-file", "label": "value-in-the-definition-file" }
```

The method returns null if there is no corresponding host name definition.

For details about the host name definition file, see [Host name definition file \(`imdd\_host\_name.conf`\)](#) in *Chapter 2. Definition Files*.

## (d) `getCategoryName` method

The `getCategoryName` method returns the category name that corresponds to `category` (ID) specified in the parameter. Use this method if the tree to be customized contains a `CATEGORY` node, and then use the return value as a label of the tree SID.

### Parameters

The following table lists and describes the parameters of the `getCategoryName` method.

Table 4–19: Parameters of the getCategoryName method

| No. | Item     | Data types | Description    |
|-----|----------|------------|----------------|
| 1   | category | string     | ID of category |

#### Return values

The getCategoryName method returns the category name that corresponds to category, according to the category name definition file for IM management nodes (imdd\_category\_name.conf).

The method returns null if there is no corresponding category name definition.

For details about the category name definition file for IM management nodes, see Category name definition file for *IM management nodes (imdd\_category\_name.conf)* in Chapter 2. Definition Files.

## (4) \_\_eventGet method

#### Description

This method returns the configuration information SIDs corresponding to all JP1 events issued by each product. Each user-created plug-in must return the configuration information SID to the individual JP1 events issued by the corresponding product. Each user-created plug-in refers to the value, such as args.productName, and determines that the plug-in itself can deal with the event.

- If a configuration information SID has been successfully generated for each one of the issued JP1 events:  
Call the args.setTargetSid (configuration information SID) method in the \_\_eventGet method.
- If an attempt to generate a configuration information SID corresponding to an issued JP1 event fails due to missing data in the JP1 event:  
Without calling the args.setError (error message) method, return from the method and exit the process.

The \_\_eventGet method is called when the Intelligent Integrated Management Base gets the JP1 event.

#### Parameters

The following table lists and describes the parameters of the \_\_eventGet method.

Table 4–20: Parameters of the \_\_eventGet method

| No. | Member                    | Description                                                                      | Remarks                                                                                          |
|-----|---------------------------|----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| 1   | productName               | Product name                                                                     | None                                                                                             |
| 2   | idBase                    | Event ID                                                                         | Decimal number                                                                                   |
| 3   | event                     | JP1 event information                                                            | event.sid: SID of the JP1 event<br>event.value: Data labeled value of the JP1 event <sup>#</sup> |
| 4   | setTargetSid (String sid) | Method that sets a configuration information SID corresponding to each JP1 event | None                                                                                             |
| 5   | setError (String message) | The method for error notification. It sets an error notification.                |                                                                                                  |

#

The data labeled value contains various attribute names and attribute values of the event. You can use the following format to retrieve the attribute value for an attribute name:

value[ 'property-name' ]

Put B. for a basic attribute or E. for an extended attribute in front of the attribute name.

Example: value[ 'E.JPC\_MGR' ]

Impact of SID information with `setTargetSid` set for it

The following table lists and describes the function that is affected by the SID information with `setTargetSid` set for it and its impact.

Table 4–21: List of affected functions

| No. | Function                 | Impact                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | System status monitoring | The JP1 event is mapped to the IM management node whose configuration information SID is <code>target</code> .<br><br>If you execute the <code>jddupdatetree</code> command in configuration change mode, the host name information provided in the configuration information SID returned with this method is used to determine the host to which to remap the JP1 event that has a configuration information SID that has been deleted from the configuration. |

## (5) `__transformEvent` method

### Description

This method converts JSON format data to JP1 events.

The `__transformEvent` method, which is implemented in user-created plug-in, or product plugin, can convert an external system-generated event received in JP1 event transformation API into a JP1 event.

### Parameters

The following table lists and describes the parameters of the `__transformEvent` method.

Table 4–22: Parameters of the `__transformEvent`

| No. | Member                                | Description                                                                                                |
|-----|---------------------------------------|------------------------------------------------------------------------------------------------------------|
| 1   | <code>eventData</code>                | Event information received from the linked product (JSON format)                                           |
| 2   | <code>jpleventmax</code>              | Maximum number of JP1 events that can be issued                                                            |
| 3   | <code>setResult(String json)</code>   | Method for setting JP1 events (JSON format) converted from event information received from linked products |
| 4   | <code>setError(String message)</code> | Methods for error notification<br>Set the error code and message.                                          |

When using `__transformEvent` method in a plug-in, it is necessary to implement it so that the `__transformEvent` method determines whether the data of the input event information is data to be processed by the plug-in.

In addition, depending on the judgment result, it is necessary to implement the JP1 event to be returned to be set to `setResult` only when the data should be processed by the plug-in. If the data is not to be processed by your plug-in, return it without setting anything.

The JP1 event to be set to `setResult` returned by the `__transformEvent` method is set in the following format.

The format of the returned JP1 event is checked by the caller's JP1 event conversion API. If malformed, the JP1 event conversion API outputs a `KAJY67000-W` message in the response body.

In addition, JP1 events exceeding 100 cannot be issued. If more than 100 JP1 events are set in `setResult`, JP1/IM - Manager issues up to 100 events from the beginning of the JP1 event sequence and does not issue subsequent events. In the plug-in, please be able to determine the details of events that were not issued by outputting them to a log.

Note that `__transformEvent` method does not check whether the value of the attribute for the JP1 event to be created is invalid or not. If the value of the attribute is invalid, JP1/IM - Manager's JP1 event conversion API will fail, and the JP1 event with the error will not be issued.

### Format of JP1 event to be returned

Format

```

{
  "pluginName": Plug-in name,
  "exceedJpleventMaxDetected": Detection of exceeding the upper limit of the number of converted JP1 events
  "events": [
    {
      "eventId": Event ID,
      "message": Message,
      "attrs": {Extended attribute name: Extended attribute value, ...}
    },
    ...
  ]
}

```

## Parameters

| No | Item name                 | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----|---------------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1  | pluginName                | String    | <p>Sets a string that represents the plug-in.</p> <p>Used to generate error messages in JP1 event conversion API<sup>#</sup>.</p> <p>This field cannot be omitted.</p>                                                                                                                                                                                                                                                                                                                         |
| 2  | exceedJpleventMaxDetected | boolean   | <p>Set whether or not to detect that the number of converted JP1 events exceeds the upper limit.</p> <ul style="list-style-type: none"> <li>If the limit is exceeded: <code>true</code></li> <li>Otherwise: <code>false</code></li> </ul> <p>This field cannot be omitted.</p> <p>If this item is <code>true</code>, the JP1 event conversion API<sup>#</sup> sets KAJY67003-W in the response body.</p>                                                                                       |
| 3  | events                    | Array     | <p>Set the JP1 event to be issued in an array.</p> <p>The maximum number of events you can set is 100.</p> <p>The plug-in using this method determines whether the upper limit has been exceeded, and if the upper limit is exceeded, set the item <code>exceedJpleventMaxDetected</code> to <code>true</code> and return it to the caller.</p>                                                                                                                                                |
| 4  | eventId                   | Array     | <p>Set the basic event ID to be issued within the following range.</p> <ul style="list-style-type: none"> <li>0 - 1FFFF</li> <li>7FFF8000 - 7FFFFFFF</li> </ul> <p>This field cannot be omitted.</p> <p>If a value outside the range is specified, JP1 Event Conversion API<sup>#</sup> sets KAJY67000-W in the response body and The <code>eventId</code> specification is out of range. Set the specified value to a value in the range of 0 - 1FFF, 7FFF8000 - 7FFFFFFF. as the factor.</p> |
| 5  | message                   | Array     | <p>Set the message text that represents the contents of the JP1 event.</p> <p>This field cannot be omitted.</p> <p>The character encoding of the message to be registered depends on the character encoding of the OS environment where JP1/IM - Manager is located.</p> <p>Set as a string of up to 1,023 bytes. If a character string of 1,024 bytes or more is specified, a character string of up to 1,023 bytes is set to the message of the JP1 event.</p>                               |
| 6  | attrs                     | String    | <p>Specify an array of extended attribute names.</p> <p>This field is optional.</p>                                                                                                                                                                                                                                                                                                                                                                                                            |

|----|-----------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    |           |           | <p>If the same extended attribute name is specified more than once, it is overwritten by the value of the last extended attribute specified.</p> <p>Extended attribute names can be names that begin with uppercase letters and contain up to 32 bytes of uppercase letters, numbers, and underscore ( _ ) lines.</p> <p>If the character string to be constructed is invalid, set KAJY67000-W in the response body of JP1 Event Conversion API* and set The extended attribute name of attrs is invalid. Please specify uppercase letters and first letters. as the factor.</p> <p>When a character string exceeding 32 bytes is specified, the JP1 event conversion API# sets KAJY67000-W as the response body and sets The extended attribute name of attrs must be a string of 32 bytes or less. as the factor.</p> <p>Also, do not specify the prefix E. for extended attribute names.</p> <p>When E. is specified, the JP1 event conversion API# sets KAJY67000-W as the response body and The extended attribute name of attrs is invalid. Please specify uppercase letters and first letters. as the factor.</p> <p>The total length of all extended attribute values can be up to 10,000 bytes.</p> <p>If the total length limit is exceeded, the JP1 event conversion API# sets KAJY67000-W as the response body and The upper limit of the extended attribute value of attrs is 10000 bytes. Specify a string of 10000 bytes or less. as the factor.</p> <p>For details on JP1 event attributes, see <a href="#">3.1 Attributes of JP1 events</a>.</p> |

#### Note #

For details of JP1 event conversion API, see [5.6.5 JP1 Event converter](#).

#### Example

```
{
  "pluginName": "PFMCS",
  "exceedJpleventMaxDetected": false
  "events": [
    {
      "eventId": "2FFF",
      "message": "xxxxxx",
      "attrs": { "SEVERITY": "Error", "JP1_SOURCEHOST": "HOSTB" }
    },
    ...
  ]
}
```

## (6) \_\_createLink method

### Description

The method generates a relation between retrieved configurations and returns it in JSON format.

- If the relation between retrieved configurations is generated successfully

In the \_\_createLink method, call the addResult (relation information between the retrieved configurations in JSON format) method.

- If the configuration information could not be retrieved  
Call the `args.setError (error message)` method, instead of the `addResult` method.

Make sure you call either the `addResult` or `args.setError` method.

The `__createLink` method is called within the `jddcreatetree` command that creates the system management tree of the Intelligent Integrated Management Base.

#### Parameters

The following table lists and describes the parameters of the `__createLink` method.

**Table 4–23: Parameters of the `__createLink` method**

| No. | Member                                 | Description                                                                                    | Remarks                                                                |
|-----|----------------------------------------|------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| 1   | <code>jplUserName</code>               | The JP1 user name                                                                              | None                                                                   |
| 2   | <code>jplToken</code>                  | A JP1 authentication token that corresponds to <code>jplUserName</code>                        |                                                                        |
| 3   | <code>simtFileList</code>              | List-formatted data of all configuration information                                           | It contains multiple IM management node objects as its data structure. |
| 4   | <code>addResult (String json)</code>   | The method to set the relation information between the retrieved configurations in JSON format | None                                                                   |
| 5   | <code>setError (String message)</code> | The method for error notification.<br>It sets an error code and a message.                     |                                                                        |

#### Format of relation information to be returned

The following describes the format of relation information between retrieved configurations returned by the `__createLink` method.

#### Formats

Format of the configuration information set for `setResult`:

```
{
  "meta":{
    "format":"file-type",
    "componentName":"name-of-the-component-whose-relation-information-is-to-be-retrieved",
    "timestamp":"generation-time-of-relation-information"
  },
  "links":[
    {
      "from":"SID-of-the-preceding-node",
      "to":"SID-of-the-succeeding-node",
      "type":"type-of-operation-target",
      "value":structured-identifier
    }, ...
  ],
}
```

#### Describe

The following table lists and describes the items of relation information between the retrieved configurations.

**Table 4–24: Items to describe the relation information between the retrieved configurations**

| No. | Item              | Data type | Description                            |
|-----|-------------------|-----------|----------------------------------------|
| 1   | <code>meta</code> | array     | Array that stores the data of the file |

| No. | Item          | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|---------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | format        | string    | The file format<br>Always set this to <code>conf</code> . This attribute cannot be omitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 3   | componentName | string    | Name of the component whose relation information is to be retrieved<br>This attribute cannot be omitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 4   | timestamp     | string    | Returns the date and time of file creation as the UTC time in ISO8601 format.<br>This attribute cannot be omitted.<br>The time is the server time of JP1/IM - Manager that generated the relation information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 5   | links         | array     | Array for relation information between configurations.<br>The order of the array is irrelevant.<br>If multiple pieces of relation information with the same <code>from</code> , <code>to</code> , and <code>type</code> values are found, these values are output with the <code>jddcreatetree</code> command, but the last relation information that appeared takes effect if the <code>jddupdatetree</code> is used to apply the information to the system.<br>However, if the configuration information is from a JP1/AJS plug-in ( <code>componentName</code> is <code>/HITACHI/JP1/AJS3/CONFINFO</code> ) and <code>type</code> is <code>rootJobnetExecutionOrder</code> (root jobnet execution order) and <code>from</code> and <code>to</code> have the same value, the Intelligent Integrated Management Base merges objects stored in the <code>value.unit</code> array into a single link object and outputs it as an IM management node link file.                                                             |
| 6   | from          | string    | Preceding node.<br>It specifies the SID of the preceding node.<br>Example<br><code>_ToolA-M_hostA/_HOST_hostA</code><br>If the <code>to</code> attribute is specified, this attribute can be omitted. It cannot accept any control character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 7   | to            | string    | Succeeding node.<br>It specifies the SID of the succeeding node.<br>Example<br><code>_ToolA-M_hostA/_ToolA-A_hostB/_HOST_hostB</code><br>If the <code>from</code> attribute is specified, this attribute can be omitted. It cannot accept any control character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 8   | type          | string    | Specifies the type of relation information.<br>It cannot accept a string starting with an underscore ( <code>_</code> ) or any control characters. Alphanumeric characters are available. The maximum number of characters is 255 bytes.<br><code>type</code> describes a grouping of relations that have the same meaning. On the <b>Related node</b> tab in the Integrated Operation Viewer window, you can filter relations to display only those belonging to a specific type.<br>For relations within a JP1/IM product or between a JP1/IM product and another product, the following types are used. In addition to these types, the use of user-specified types is also allowed. <ul style="list-style-type: none"> <li>• <code>rootJobnetExecutionOrder</code>: Relation of the execution order of root jobnets</li> <li>• <code>rootJobnetAgent</code>: Relation between a root jobnet and an AJS agent</li> <li>• <code>managerAgent</code>: Relation between the manager and agent of a JP1 product</li> </ul> |

| No. | Item  | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Example

The following shows an example of retrieving information with the `__createLink` method.

```
{
  "meta":{
    "format":"conf"
    "componentName":"/HITACHI/JP1/AJS3/CONFINFO"
    "timestamp":"2018-11-11T00:00:00Z"
  },
  "links":[
    {
      "from":"JP1AJS-M_AJSM1/_HOST_AJShost1/_JP1SCHE_S1/_JP1JOBG_JG1/_JP1ROOTJOBNET_root1",
      "to":"JP1AJS-M_AJSM2/_HOST_AJShost2/_JP1SCHE_S2/_JP1JOBG_JG2/_JP1ROOTJOBNET_root2",
      "type":"rootJobnetExecutionOrder",
      "value":{
        {
          "precedingJob":"root1/job1",
          "succeedingJob":"root2/job2",
        }
      }, ...
    ],
  ],
}
```

### Impact of relation information set by addResult

The following table lists and describes the functions that are affected by the relation information set by `addResult` and its impact.

Table 4–25: List of affected functions

| No. | Function                                                | Impact                                                                                                                                                                     |
|-----|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | System status monitoring                                | The IM management node acquisition function outputs the IM management node link object as an IM management node link file.                                                 |
| 2   | Integrated monitoring of systems by IM management nodes | Relations are displayed in the <b>Workflow</b> tab according to IM management node links with type of <code>rootJobnetExecutionOrder</code> (root jobnet execution order). |

| No. | Function                                    | Impact                                                                                                                                                                                                                                                                                                |
|-----|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | Related node display                        | Relations are displayed in the <b>Related node</b> tab according to IM management node links.                                                                                                                                                                                                         |
| 4   | Linked unit display                         | If an IM management node link has a type of <code>rootJobnetExecutionOrder</code> (root jobnet execution order), the unit information (including the result of <code>__linkValueGet</code> ) specified for unit of the link's additional information (value) is displayed.                            |
| 5   | Display of impact on following root jobnets | If an IM management node link has a type of <code>rootJobnetExecutionOrder</code> (root jobnet execution order), the impact (result of <code>__linkValueGet</code> ) of the unit (latest generation) specified for unit of the link's additional information (value) on following units is displayed. |

## (7) \_\_linkValueGet method

### Description

A method that adds dynamic grant information to the value parameter and returns an array of link information in the given JSON format.

If the plugin contains link information that cannot be processed, the link information will be returned as is.

### Parameters

The following table lists and describes the parameters of the `__linkValueGet` method.

Table 4–26: Parameters of the `__linkValueGet` method

| No. | Member      |       | Description                                                                                                                                                                                                                                                                                                                                                                                                        | Remarks                                                                       |
|-----|-------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| 1   | jplUserName |       | The JP1 user name                                                                                                                                                                                                                                                                                                                                                                                                  | None                                                                          |
| 2   | jplToken    |       | A JP1 authentication token that corresponds to jplUserName                                                                                                                                                                                                                                                                                                                                                         |                                                                               |
| 3   | linksData   |       | An object for a link information object array                                                                                                                                                                                                                                                                                                                                                                      |                                                                               |
| 4   |             | links | An array of link information objects                                                                                                                                                                                                                                                                                                                                                                               | It cannot be omitted. An empty array cannot be specified.                     |
| 5   |             | from  | SID of the preceding node                                                                                                                                                                                                                                                                                                                                                                                          | None                                                                          |
| 6   |             | to    | SID of the succeeding node                                                                                                                                                                                                                                                                                                                                                                                         |                                                                               |
| 7   |             | type  | Type of the target                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                               |

| 9   | select      |       | <p>An array of value parameters to be retrieved.</p> <p>If you want to further specify an object or a member of an object array, specify <i>object-name.member-name</i>.</p> <p>If you want to specify only "impact" in the following example, specify "unit.impact" in select:</p> <pre> "value":{   "unit": [     {       "precedingJob":"job1 ",       "succeedingJob":"job 2"       "impact":true     } </pre> | <p>It can be omitted.</p> <p>If omitted, it retrieves all the parameters.</p> |

| No. | Member                   | Description                                                     | Remarks |
|-----|--------------------------|-----------------------------------------------------------------|---------|
|     |                          | <pre>] }</pre>                                                  |         |
| 10  | setResult(String json)   | The method to set link information in JSON format               | None    |
| 11  | setError(String message) | The method for error notification.<br>It sets an error message. |         |

Format of link information to be returned

The following describes the format of link information returned by the `__linkValueGet` method.

#### Formats

```
{
  "links": [
    {
      "from": "the-preceding-node-SID",
      "to": "the-succeeding-node-SID",
      "type": "type-of-the-target",
      "value": structured-identifier
    }, ...
  ]
}
```

#### Describe

The following table lists and describes the items of retrieved link information.

Table 4–27: Items of the retrieved link information

| No. | Item  | Data types | Description                                                                      |
|-----|-------|------------|----------------------------------------------------------------------------------|
| 1   | links | array      | An array of link information                                                     |
| 2   | from  | string     | SID of the preceding node                                                        |
| 3   | to    | string     | SID of the succeeding node                                                       |
| 4   | type  | string     | Type of the target                                                               |
| 5   | value | Object     | Specifies additional information of relation information between configurations. |

#### Example

The following shows an example of retrieving information with the `__linkValueGet` method.

```
{
  "links": [
    {
      "from": "_JP1AJS-M_HOST1/_HOST_HOST1/_JP1SCHE_schedulerserv/_JP1JOBG_jobgroup/_JP1ROOTJOBNET_jobnet1",
      "to": "_JP1AJS-M_HOST1/_HOST_HOST1/_JP1SCHE_schedulerserv/_JP1JOBG_jobgroup/_JP1ROOTJOBNET_jobnet2",
      "type": "rootJobnetExecutionOrder",
      "value": {
        "unit": [
          {
            "precedingJob": "job1",
            "succeedingJob": "job2",
            "succeedingJobStartTime": "2019-05-14T00:00:00Z",
            "precedingJobURL": "http://10.220.196.82:22252/ajs/..."
          }
        ]
      }
    }
  ]
}
```

```

",
    "succeedingJobURL":"http://10.220.196.82:22252/ajs/..
.",
    "impact":"error"
  }, ...
],
  "msg":"KAJY04254-E The collecting information process coul
d not be generated."
}
}, ...
]
}

```

#### Impact of additional information (value) of a link set by setResult

The following table lists and describes the functions that are affected by the additional information (value) of a link set by setResult and its impact.

**Table 4–28: List of affected functions**

| No. | Function                                    | Impact                                                                                                                                                                                                                                                                                                           |
|-----|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Linked unit display                         | If an IM management node link has a type of <code>rootJobnetExecutionOrder</code> (root jobnet execution order), the information specified for unit of the link's additional information (value) is displayed.<br>In addition, the URL parameter is used to start the WWW browser on which the URL is specified. |
| 2   | Display of impact on following root jobnets | If an IM management node link has a type of <code>rootJobnetExecutionOrder</code> (root jobnet execution order), the impact of the unit (latest generation) specified for unit of the link's additional information (value) on following units is displayed.                                                     |

## (8) \_\_simtLoad method

### Description

This method is called to collect the required related information when IM management node is loaded. Called from simt service when the managed node is updated with the following actions:

- When simtData loading is completed at service startup
- When simtData loading is completed when the jddupdatetree command is executed

Collected information can be provided to other methods, for example, by setting the information to a global variable. For example, if the \_\_simtLoad method collects AJS manager host name and AJS Agent host and set it global variable, you can refer to it in other methods (\_\_eventGet method).

- When related information retrieval is completed normally  
You can provide information about other methods, for example by setting the global variable.
- Failed to get related information  
Ensure that you call args.setError (error message) method.

### Parameters

The following table lists and describes the parameters of the \_\_simtLoad method.

| N o. | Member                                | Description                                                        | Remarks                                                                 |
|------|---------------------------------------|--------------------------------------------------------------------|-------------------------------------------------------------------------|
| 1    | <code>simtDataList</code>             | All itemized lists of configuration <code>simtData</code>          | All <code>simtData</code> in the master information of the managed node |
| 2    | <code>setError(String message)</code> | Methods for error notifications<br>Set the error code and Message. | None                                                                    |

## (9) `__metricListGet` method

### Description

The method retrieves the list of metrics that can be displayed for time-series data and returns it in JSON format.

### Parameters

The following table lists and describes the parameters of the `__metricListGet` method.

Table 4–29: Parameters of the `__metricListGet` method

| No. | Member                                | Description                                                                | Remarks |
|-----|---------------------------------------|----------------------------------------------------------------------------|---------|
| 1   | <code>jplUserName</code>              | The JP1 user name                                                          | None    |
| 2   | <code>jplToken</code>                 | A JP1 authentication token that corresponds to <code>jplUserName</code>    |         |
| 3   | <code>sid</code>                      | A configuration information SID whose list of metrics you want to retrieve |         |
| 4   | <code>lang</code>                     | Language for the list of metrics to be retrieved                           |         |
| 5   | <code>setResult(String json)</code>   | The method to set the list of metrics retrieved in JSON format             |         |
| 6   | <code>setError(String message)</code> | The method for error notification.<br>It sets an error message.            |         |

### Format of the list of metrics to be returned

The following shows the list of metrics returned by the `__metricListGet` method.

### Formats

```
{
  "metrics": [
    {
      "name": "metric",
      "label": "metric-display-name",
      "category": "category-of-the-metric",
      "description": "description-of-the-metric",
      "default": default-setting
    }
    ...
  ]
}
```

### Describe

The following table lists and describes the items of the retrieved list of metrics.

Table 4–30: Items of the retrieved list of metrics

| No. | Item                 | Data types | Description                     |
|-----|----------------------|------------|---------------------------------|
| 1   | <code>metrics</code> | array      | An array of metric information. |

| No. | Item        | Data types | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|-------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |             |            | You can specify up to 100 elements. An empty array cannot be specified. This item cannot be omitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| 4   | category    | string     | <p>The category of the metric.</p> <p>It can be specified between 1 and 255 characters, excluding control characters. An empty string cannot be specified. This item can be omitted.</p>                                                                                                                                                                                                                                                                                                                                                                                                       |
| 5   | description | string     | <p>The description of the metric.</p> <p>It can be specified between 1 and 1023 characters, excluding control characters. An empty string cannot be specified. This item can be omitted.</p> <p>If a long string is specified in this item, when you use the Integrated Operation Viewer window of JP1/IM - Manager (Intelligent Integrated Management Base), a string displayed as a tooltip for the metric display name in the <b>Trends</b> tab might be truncated by WWW browser limitations (maximum number of characters that can be displayed as the <code>title</code> attribute).</p> |
| 6   | default     | boolean    | <p>Specifies whether the metric is a default metric.</p> <ul style="list-style-type: none"> <li>• <code>true</code>: It is a default metric.</li> <li>• <code>false</code>: It is not a default metric.</li> </ul> <p>You can specify up to 10 metrics as the default metrics. This item cannot be omitted.</p>                                                                                                                                                                                                                                                                                |

### Example

The following shows an example of retrieving information with the `__metricListGet` method.

```
{
  "metrics": [
    {
      "name": "CPU-Usage",
      "label": "CPU-used-rate",
      "category": "CPU",
      "description": "Show the CPU usage on a core basis. (Units: %)",
      "default": true
    }
    ...
  ]
}
```

### Impact of the list of metrics set by `setResult`

The following table lists and describes the function that is affected by the list of metrics set by `setResult` and its impact.

Table 4–31: List of affected functions

| No. | Function                  | Impact                                                                                                                                    |
|-----|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Trend information display | In the trend graph settings area of the <b>Trends</b> tab, the metrics are displayed as candidates of metrics to be displayed in a chart. |

## (10) \_\_timeSeriesDataGet method

### Description

The method retrieves time-series data and returns it in JSON format.

If the number of time-series data sets retrieved and the number of instances exceed the limits specified by `countPerInstance` and `instanceCount` respectively, the applicable member of the `exceedCountDetected` object in the response is set to `true` and the data is selected so that the numbers of data sets are below the limits of `countPerInstance` and `instanceCount`, and then the data is returned.

### Parameters

The following table lists and describes the parameters of the `__timeSeriesDataGet` method.

Table 4–32: Parameters of the `__timeSeriesDataGet` method

| No. | Member                                    | Description                                                                                                                                       | Remarks                                                                                                                                                             |
|-----|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>jplUserName</code>                  | The JP1 user name                                                                                                                                 | None                                                                                                                                                                |
| 2   | <code>jplToken</code>                     | A JP1 authentication token that corresponds to <code>jplUserName</code>                                                                           |                                                                                                                                                                     |
| 3   | <code>sid</code>                          | A configuration information SID whose time-series data you want to retrieve                                                                       |                                                                                                                                                                     |
| 4   | <code>lang</code>                         | Language for time-series data to be retrieved                                                                                                     |                                                                                                                                                                     |
| 5   | <code>metric</code>                       | The name of the metric.<br>It must be specified between 1 and 255 characters.<br>An empty array cannot be specified. This item cannot be omitted. |                                                                                                                                                                     |
| 6   | <code>startTime</code>                    | Specifies the start date and time of the time-series data as the UTC time in ISO8601 format. Do not specify seconds after the decimal point.      |                                                                                                                                                                     |
| 7   | <code>endTime</code>                      | Specifies the end date and time of the time-series data as the UTC time in ISO8601 format. Do not specify seconds after the decimal point.        |                                                                                                                                                                     |
| 8   | <code>countPerInstance</code>             | The upper limit of the number of data sets per instance in those to be retrieved                                                                  | It is ensured that a value obtained by multiplying the <code>countPerInstance</code> value by the <code>instanceCount</code> value is less than or equal to 30,000. |
| 9   | <code>instanceCount</code>                | The upper limit of instances                                                                                                                      |                                                                                                                                                                     |
| 10  | <code>setResult</code><br>(String json)   | The method to set time-series data in JSON format                                                                                                 | None                                                                                                                                                                |
| 11  | <code>setError</code><br>(String message) | The method for error notification.<br>It sets an error message.                                                                                   |                                                                                                                                                                     |

### Format of time-series data to be returned

The following shows the time-series data returned by the `__timeSeriesDataGet` method.

#### Formats

```
{
  "metric": "metric",
  "timeSeriesData": [
    {
      "instance": "instance-name"
      "unit": "unit",
      "data": [
```

```

        {"time": "time", "value": value},
        ...
    ]
},
...
],
"exceedCountDetected": {
    countPerInstance: whether-an-excess-of-the-upper-limit-for-the-n
umber-of-data-sets-per-instance-is-detected,
    instanceCount: whether-an-excess-of-the-upper-limit-for-the-num
ber-of-instances-is-detected
}
}

```

## Describe

The following table lists and describes the items of the retrieved time-series data.

**Table 4–33: Items of the retrieved time-series data**

| No. | Item                | Data types | Description                                                                                                                                                                                                                                                                                                                  |
|-----|---------------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | timeSeriesData      | array      | An array of time-series data.<br>An empty array cannot be specified. This item cannot be omitted.                                                                                                                                                                                                                            |
| 2   | metric              | string     | The name of the metric.<br>It can be specified with half-width alphanumeric characters and the following symbols:<br>– (hyphen), _ (underscore)<br>It must be specified between 1 and 255 characters.<br>An empty string cannot be specified. This item cannot be omitted.                                                   |
| 3   | instance            | string     | The name of the instance.<br>It can be specified between 1 and 255 characters, excluding control characters. An empty string cannot be specified. This item can be omitted.                                                                                                                                                  |
| 4   | unit                | string     | The unit for the metric.<br>It can be specified between 1 and 255 characters, excluding control characters. An empty string cannot be specified. This item cannot be omitted.                                                                                                                                                |
| 5   | data                | array      | An array of two-dimensional data consisting of the time and value.<br>If no time-series data exists in the specified period, specify an empty array.<br>This item cannot be omitted.                                                                                                                                         |
| 6   | time                | string     | The time of data.<br>It is the UTC time in ISO8601 format. The number of seconds after the decimal point cannot be specified. <ul style="list-style-type: none"> <li>If data is empty: This item can be omitted.</li> <li>If data is not empty: This item cannot be omitted. An empty string cannot be specified.</li> </ul> |
| 7   | value               | number     | A value of data.<br>It should be the same as the accuracy of number in JavaScript. <ul style="list-style-type: none"> <li>If data is empty: This item can be omitted.</li> <li>If data is not empty: This item cannot be omitted.</li> </ul>                                                                                 |
| 8   | exceedCountDetected | Object     | The object to detect the upper limit.<br>This item cannot be omitted.                                                                                                                                                                                                                                                        |
| 9   | countPerInstance    | boolean    | Whether an excess of the upper limit for the number of data sets per instance is detected.                                                                                                                                                                                                                                   |

| No. | Item          | Data types | Description                                                                                                                                                                                                                     |
|-----|---------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |               |            | <ul style="list-style-type: none"> <li>• If the upper limit is exceeded: true</li> <li>• Otherwise: false</li> </ul> This item cannot be omitted.                                                                               |
| 10  | instanceCount | boolean    | Whether an excess of the upper limit for the number of instances is detected. <ul style="list-style-type: none"> <li>• If the upper limit is exceeded: true</li> <li>• Otherwise: false</li> </ul> This item cannot be omitted. |

### Example

The following shows an example of retrieving information with the `__timeSeriesDataGet` method.

```
{
  "metric": "CPU Usage",
  "timeSeriesData": [
    {
      "instance": "CPU_1",
      "unit": "%",
      "data": [
        { "time": "2019-05-22T00:00:00Z", "value": 14.04 },
        ...
      ]
    },
    {
      "instance": "CPU_2",
      "unit": "%",
      "data": [
        { "time": "2019-05-22T00:00:00Z", "value": 09.24 },
        ...
      ]
    },
    ...
  ],
  "exceedCountDetected": {
    "countPerInstance": true,
    "instanceCount": false
  }
}
```

If no data exists for the specified metric and in the specified period

```
{
  "metric": "CPU Usage",
  "timeSeriesData": [
    {
      "unit": "%",
      "data": [
      ]
    }
  ],
  "exceedCountDetected": {
    "countPerInstance": false,
    "instanceCount": false
  }
}
```

```
}
```

#### Impact of the time-series data set by setResult

The following table lists and describes the function that is affected by the time-series data set by setResult and its impact.

Table 4–34: List of affected functions

| No. | Function                  | Impact                                      |
|-----|---------------------------|---------------------------------------------|
| 1   | Trend information display | The trend of time-series data is displayed. |

## (11) \_\_urlGet method

### Description

The method retrieves the URL for starting a monitor associated with the specified SID and returns it in JSON format.

### Parameters

The following table lists and describes the parameters of the \_\_urlGet method.

Table 4–35: Parameters of the \_\_urlGet method

| No. | Member                       | Description                                                                                        | Remarks |
|-----|------------------------------|----------------------------------------------------------------------------------------------------|---------|
| 1   | jplUserName                  | The JPl user name                                                                                  | None    |
| 2   | jplToken                     | A JPl authentication token that corresponds to jplUserName                                         |         |
| 3   | sid                          | A configuration information SID whose URL for starting the associated monitor you want to retrieve |         |
| 4   | setResult<br>(String json)   | The method to set the URL information in JSON format                                               |         |
| 5   | setError<br>(String message) | The method for error notification.<br>It sets an error message.                                    |         |

### Format of the URL for starting the monitor to be returned

The following shows the URL for starting the monitor returned by the \_\_urlGet method.

#### Formats

```
{
  urlList:[
    {
      "url":"URL-for-starting-the-monitor",
      "name":"name-of-the-URL"
    },
    ...
  ]
}
```

#### Describe

The following table lists and describes the items of the retrieved URL for starting the monitor.

Table 4–36: The items of the retrieved URL for starting the monitor

| No. | Item    | Data types | Description                         |
|-----|---------|------------|-------------------------------------|
| 1   | urlList | array      | An array of URL information objects |

| No. | Item | Data types | Description         |
|-----|------|------------|---------------------|
| 2   | url  | string     | The URL string      |
| 3   | name | string     | The name of the URL |

#### Example

The following shows an example of retrieving information with the `__urlGet` method.

```
{
  urlList:[
    {
      "url":"http://10.220.196.82:22252/ajs/login.html?manager=10.22
0.196.82&type=monitor...",
      "name":"monitor-startup-window-for-rootJobNet1"
    }
  ]
}
```

#### Impact of the URL information set by setResult

The following table lists and describes the function that is affected by the URL information for starting the monitor set by `setResult` and its impact.

**Table 4–37: List of affected functions**

| No. | Function                             | Impact                                                                                                                                                                                 |
|-----|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Opening a window of a linked product | A window of a linked product is opened for the IM management node with <code>__urlGet</code> specified for methods of additional information (value) in the configuration information. |

## 4.4.5 Exception handling

If an exception occurs in a method of the user-created plug-in, it should be caught (`catch`) within that method. If an exception occurs in a method of the plug-in, set the error and message that correspond to the exception to the argument of the error message method (`args.setError`) and then call the method. Use English for the language of the error message you set.

Note that after the error message method (`args.setError`) is called, the plug-in will never get the control back.

The following message is printed to the integrated trace log or window:

```
KAJY02028-W An attempt to acquire the system configuration information that
manages JP1/IM - Manager has failed. (Host name: host-name, Component name:
component-name, Details: details)
```

#### *host-name*

The name of the host from which information could not be retrieved

#### *component-name*

The name of the component from which information could not be retrieved

#### *details*

The contents of the message returned by the `setError` method

For details on the error message method (`args.setError`), see [4.4.4\(1\) `\_\_configurationGet` method](#) in *4.4 Methods implemented in the plug-in*.

For details on the messages, see the *JP1/Integrated Management 3 - Manager Messages*.

## 4.5 Methods available in the user-created plug-in

The following table lists and describes the methods that are commonly available in the methods of the user-created plug-in.

Table 4–38: List of methods commonly available in the methods of the user-created plug-in

| No. | Method name <sup>#</sup>                      | Description                                                                                                                                                                                                                                                       |
|-----|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>jplImdd.callRest</code>                 | The method to call the REST API                                                                                                                                                                                                                                   |
| 2   | <code>jplImdd.readFile</code>                 | The method to read a file and return the content of the file as a string                                                                                                                                                                                          |
| 3   | <code>jplImdd.encodeBase64</code>             | The method to convert a string into a Base64-formatted value and return it                                                                                                                                                                                        |
| 4   | <code>jplSimtService.get</code>               | The method to return the configuration information SID and the data labeled value                                                                                                                                                                                 |
| 5   | <code>jplSimtService.join</code>              | The method to return the configuration information SID that has been generated by combining structured identifiers                                                                                                                                                |
| 6   | <code>jplSimtService.pack</code>              | The method to return the structured identifier generated by combining the class and name of the structured identifier that takes a non-host-name value for the name                                                                                               |
| 7   | <code>jplSimtService.packHost</code>          | The method to return the structured identifier generated by combining the class and name of the structured identifier that takes a host name for the name                                                                                                         |
| 8   | <code>jplSimtService.parse</code>             | The method to split a configuration information SID into structured identifiers, separate each structured identifier into the class part and the URL-decoded name part with the underscore ( <code>_</code> ) between them removed, and return the resulting data |
| 9   | <code>jplLogger.trace</code>                  | The method for logging                                                                                                                                                                                                                                            |
| 10  | <code>jplImdd.execCmd</code>                  | The method to execute a command remotely                                                                                                                                                                                                                          |
| 11  | <code>jplImdd.getPluginConfDirPath</code>     | The method to return the absolute path to the parent directory of the directory that stores plug-in definition files                                                                                                                                              |
| 12  | <code>jplImdd.getVersion</code>               | The method to return the version of JP1/IM                                                                                                                                                                                                                        |
| 13  | <code>jplEmService.getEvent</code>            | The method to retrieve events related to an IM management node from the integrated monitoring database                                                                                                                                                            |
| 14  | <code>jplSimtService.getLink</code>           | The method to retrieve link information                                                                                                                                                                                                                           |
| 15  | <code>jplEmService.changeEventStatus</code>   | The method to change the event status                                                                                                                                                                                                                             |
| 16  | <code>jplSimtService.getTreeSid</code>        | The method to retrieve the tree SID corresponding to the specified configuration information SID                                                                                                                                                                  |
| 17  | <code>jplTrendDataService.getTrendData</code> | Methods that retrieve trend data (time-series data) from Trend data Management Database                                                                                                                                                                           |
| 18  | <code>jplTrendDataService.getLabelList</code> | A method that retrieves a list of time series of label sets from Trend data Management Database that Match to a parameter-specified condition.                                                                                                                    |

#

`jplImdd`, `jplSimtService`, and `jplLogger` of these methods represent a global object. So, do not define a global object with the same name as one of these names. Also, do not define a global object with the name that starts with `jpl` or `hitachi`.

## 4.5.1 jp1Imdd.callRest

This method calls a REST API. The following table shows the details of the `jp1Imdd.callRest` method.

### Method name

```
Object jp1Imdd.callRest(String method, String url, Object headers,
String body)
```

### Parameters

`method`

A method of a REST API

`url`

The URL of the REST API

When the URL including host name is specified, register the host name to the integrated manager's hosts file and DNS so as to enable name resolution on the integrated manager host. Configuration in `jp1hosts` file and `jp1hosts2` file are not referred.

`_headers`

The request header of the REST API

`body`

The request body of the REST API

If the GET method is specified and the body is not needed, set `body` to null or an empty character.

### Return values

An object that stores the response from the REST API.

The object contains the following keys and values:

| No. | Description                                                                  | Key        | Value                               |
|-----|------------------------------------------------------------------------------|------------|-------------------------------------|
| 1   | If the REST API is completed successfully                                    | "response" | response object                     |
|     |                                                                              | "status"   | HTTP status code                    |
|     |                                                                              | "headers"  | response header                     |
|     |                                                                              | "body"     | response body                       |
| 2   | If the analysis of the URI fails                                             | "error"    | error object                        |
|     |                                                                              | "status"   | 0                                   |
|     |                                                                              | "body"     | string indicating an analysis error |
| 3   | If the HTTP status code is 4xx or 5xx, or an unknown status code is returned | "error"    | error object                        |
|     |                                                                              | "status"   | HTTP status code                    |
|     |                                                                              | "headers"  | response header                     |
|     |                                                                              | "body"     | response body                       |

### Exception

`RestClientException`

- When an I/O error occurs

## Call example

```
module.exports = function(args) {
    var baseUrl = args.baseUrl;
    var manager = args.manager;
    var jpltoken = args.jpltoken;

    var method = 'POST';
    var apiPath = '/v1/authorization/token';
    var url = baseUrl + apiPath;
    var headers = {
        'Accept': 'application/json',
        'Content-Type': 'application/json',
        'X-AJS-Authorization-Token': jpltoken,
    };
    var body = {
        parameters: {
            manager: manager,
            serviceName: 'AJSROOT1',
        }
    };
    return jplImdd.callRest(method, url, headers, JSON.stringify(body));
}
```

## 4.5.2 jplImdd.readFile

This method reads a file located at the path specified by the parameter and returns its content as string type. This method can read a UTF-8 encoded file. The following table shows the details of the `jplImdd.readFile` method.

### Method name

`String jplImdd.readFile(String pathname)`

### Parameters

`pathname`

The absolute path to the file to be read by the method.

Separate the path with a forward slash (/) or backslash (\).

### Return values

The content of the file the method read

If a BOM is placed in the file, a string without the BOM is returned.

### Exception

`FileNotFoundException`

- The file cannot be opened for some reasons
- If the file does not exist, the file is not a normal file but a directory

`IOException`

- If an I/O error occurs

### 4.5.3 jp1Imdd.encodeBase64

This method encodes a string specified by the parameter in Base64 format and returns it as string type. The following table shows the details of the `jp1Imdd.encodeBase64` method.

Method name

```
String jp1Imdd.encodeBase64(String str)
```

Parameters

```
str  
String to be Base64-encoded
```

Return values

```
Base64-encoded string
```

Exception

```
None
```

### 4.5.4 jp1SimtService.get

Based on the configuration information SID specified in its parameter, this method returns the `SimtData` object that puts together the SID in question and the data labeled `value`. The following table shows the details of the `jp1SimtService.get` method.

Method name

```
SimtData jp1SimtService.get(String sid)
```

Parameters

```
sid  
String representing the configuration information SID
```

Return values

```
SimData object that puts together the configuration information SID and the data labeled value  
If the configuration information SID specified in the parameter does not exist, this method returns null.  
The SimtData object has the following fields:
```

- `String sid`
- `Map<String, Object> value`

Exception

```
None
```

### 4.5.5 jp1SimtService.join

This method generates a configuration information SID by combining the structured identifiers specified in its parameter by inserting a slash (/) between them, and returns the generated configuration information SID in string format. The following table shows the details of the `jp1SimtService.join` method.

Method name

```
String jp1SimtService.join(String... sid)
```

## Parameters

`sid`

Structured identifiers that are combined using slash (/)

## Return values

String representing the configuration information SID that consists of multiple strings representing the structured identifiers specified in the parameter, combined with a slash (/)

## Exception

None

## 4.5.6 jp1SimtService.pack

This method encloses the class (without underscores) in the structured identifier specified by the first parameter with underscores (`_`), URL-encodes symbols other than `.`, `~`, `-`, and `:`, and non-alphanumeric characters in the name specified by the second parameter, concatenates the class with the name in this order, and then returns the generated structured identifier as string type. The following table shows the details of the `jp1SimtService.pack` method.

### Method name

```
String jp1SimtService.pack(String key, String value)
```

### Parameters

`key`

The class in the structured identifier that is to be enclosed with underscores (`_`)

Class in the structured identifier that takes a non-host-name value for the name

`value`

The name in the structured identifier to be URL-encoded

### Return values

A structured identifier string created by combining the class string enclosed by underscores (`_`) with the URL-encoded name string

### Exception

None

## 4.5.7 jp1SimtService.packHost

This method encloses the class (without underscores), for which the name of the structured identifier accepts a host name, in the structured identifier specified by the first parameter with underscores (`_`). Then, the method converts the host name specified by the second parameter into uppercase characters and URL-encodes symbols other than `.`, `~`, `-`, and `:`, and non-alphanumeric characters, concatenates the class with the name in this order, and then returns the generated structured identifier as string type. If you create a structured identifier that has a non-host-name value for the name, use the `jp1SimtService.pack` method. The following table shows the details of the `jp1SimtService.packHost` method.

### Method name

```
String jp1SimtService.pack(String key, String value)
```

## Parameters

key

The class in the structured identifier that is to be enclosed with underscores ( \_ )

Class in the structured identifier that takes a non-host-name value for the name

value

The host name that is converted into uppercase characters and URL-encoded

## Return values

A structured identifier string created by combining the class string enclosed by underscores ( \_ ) with the URL-encoded name string

## Exception

None

## 4.5.8 jp1SimtService.parse

This method splits the SID specified by the parameter into structured identifiers and separates the identifiers into classes without underscores ( \_ ) and URL-decoded names. The method then stores these pairs of classes and names in `SimtIdUnit` objects and returns a `List` that contains the `SimtIdUnit` objects. If the SID is split into structured identifiers but these identifiers are not in the valid structured identifier format, such identifiers are stored in the `SimtIdUnit` object as name values. The following table shows the details of the `jp1SimtService.parse` method.

### Method name

```
List<SimtIdUnit> jp1SimtService.parse(String sid)
```

## Parameters

sid

String that represents the SID

## Return values

A `List` object that contains `SimtIdUnit` objects storing the class obtained by splitting the SID into structured identifiers and removing underscores ( \_ ) from it, together with the URL-decoded name

The `SimtIdUnit` object has the following fields:

- `String key`: Class without underscores
- `String value`: Name

## Exception

None

## 4.5.9 jp1Logger.trace

This method writes the string in the second parameter to the file specified by the first parameter as a log. The following table shows the details of the `jp1Logger.trace` method.

### Method name

```
void jp1Logger.trace(String jsName, String message)
```

## Parameters

`jsName`

Specify the file name of the user-created plug-in for the file name parameter. The logs are output to the location where the user-created plug-in is located. A single row can contain up to 4,096 bytes. If the log exceeds the upper limit, the portion beyond the limit is not written to the file.

`message`

The output message

## Return values

None

## Exception

None

## 4.5.10 jp1Imdd.execCmd

This method executes a command specified in the parameter. The following table shows the details of the `jp1Imdd.execCmd` method.

### Method name

```
Object jp1Imdd.execCmd(String host, String cmd, Object env, String envFile,
String jp1user)
```

### Parameters

If the file specified by `envFile` also contains the environment variable specified by `env`, the value specified by `env` takes precedence.

`host`

Specifies the name of the command execution host from 1 to 255 bytes.

`cmd`

Specifies the command to be executed and its arguments from 1 to 4,095 bytes. If the command name contains any space character, it must be enclosed in double quotation marks ("").

`env`

Specifies the environment variable value for the value of the object, using the environment variable when the command is executed on the execution host as a key to the object. Up to 30 `env` parameters can be specified.

If it is not needed, specify null. Specify both the object key and value together from 1 to 7,107 bytes.

`envFile`

The name of the environment variable file. Specify the absolute path to the file on the execution host between 1 and 255 bytes. If it is not needed, specify null or an empty string.

`jp1user`

Specifies a JP1 user name from 1 to 31 bytes. If the value is specified, the command is executed as the primary user of the specified JP1 user. If it is not needed, specify null or an empty string.

### Return values

An object that stores the execution result of the command. The object contains the following keys and values:

| No | Description                                                                                          | Key        | Value                                                                    |
|----|------------------------------------------------------------------------------------------------------|------------|--------------------------------------------------------------------------|
| 1  | If the command is executed remotely and successfully (the executed command is started successfully)# | "response" | response object                                                          |
|    |                                                                                                      | "rc"       | Return value of the executed command                                     |
|    |                                                                                                      | "stdout"   | String of the standard output of the command, converted into UTF-8       |
|    |                                                                                                      | "stderr"   | String of the standard error output of the command, converted into UTF-8 |
| 2  | If the remote execution of the command fails (the executed command cannot be started successfully)   | "error"    | error object                                                             |
|    |                                                                                                      | "rc"       | error code                                                               |

#:  
Even if the execution command specified in `cmd` does not exist, if the connection to the execution host is successfully established and `cmd.exe` or `/bin/sh` starts up, the return value, standard output, and standard error output are returned. Furthermore, the return value, standard output, and standard error output that are returned depend on the `cmd.exe` or `/bin/sh` of the execution host.

## Exception

`IOException`

- When an I/O error occurs

## Prerequisite

To use this method, JP1/Base 12-10 or later must be installed in the execution host and added to IM configuration management.

## Commands that can be executed

The following shows the types of commands that can be executed by the `jp1Imdd.execCmd` command.

If a command is executed on a Windows host:

- Executable file (`.com`, `.exe`)
- Batch file (`.bat`)

If a command is executed on a UNIX host:

- UNIX command
- Shell script

## Important

If a command is executed, it works assuming that the language setting is the same as the one with which JP1/Base is running. Do not change characters with the `LANG` environment variable.

The following commands cannot be executed:

- Command that needs interactive operations
- Command that opens a window
- Command that involves escape sequences and control codes
- Command that does not exit, such as a daemon

- Command that needs interactions with the desktop, such as the Windows messaging mechanism and DDE (In Windows)
- Command that shuts down the OS, such as `shutdown` and `halt`
- Command that exits JP1/Base
- `jbs_spmd_reload` command

#### How to execute a command

The remote command execution function executes a command with the following operations.

In Windows:

```
cmd.exe /c specified-command
```

In UNIX:

The login shell of the OS user is used. If it is not specified, `/bin/sh` is used.

```
/bin/sh -c specified-command
```

#### Execution user

The command is executed as the primary user of the JP1 user specified in the `jp1User` argument. If `jp1User` is set to null or an empty string, the command is executed with the following privilege of the execution host.

- In Windows: `SYSTEM`
- In UNIX: `root`

### Important

If UAC is enabled on the execution host, the primary user of the JP1 user specified by the `jp1User` argument must be the built-in Administrator user.

#### Limits

The following table describes the limits that apply to `jp1Imdd.execCmd` method.

**Table 4–39: Limitations to `jp1Imdd.execCmd` method**

| No. | item                                                       | Value to be specified |
|-----|------------------------------------------------------------|-----------------------|
| 1   | Time out (second)                                          | 3600                  |
| 2   | Size of the standard output and standard error output (MB) | 20                    |

#### Error code

The following table shows the error codes when the execution target command fails to be started.

**Table 4–40: Error codes when the execution target command fails to be started**

| No. | Error case                                | Error code | Status                                                                                                                    |
|-----|-------------------------------------------|------------|---------------------------------------------------------------------------------------------------------------------------|
| 1   | The specified parameter is invalid        | 1          | Revise the specified parameter and re-execute the command.                                                                |
| 2   | A connection to the execution host failed | 2          | Check to see if the JP1/Base service is running on the execution host.                                                    |
| 3   | A timeout occurred <sup>#</sup>           | 3          | A timeout occurred due to a high load on the execution host or the network. Wait a while and then re-execute the command. |

| No. | Error case                                           | Error code | Status                                                                                                                                                                                                                                                              |
|-----|------------------------------------------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | The amount of incoming data exceeded its upper limit | 4          | The size of the standard output or the standard error output for the executed command exceeded its upper limit. Revise the output of the executed command.                                                                                                          |
| 5   | The environment variable file cannot be read         | 5          | Check to see if the file specified by the <code>envFile</code> argument exists on the execution host.                                                                                                                                                               |
| 6   | The JP1 user is invalid                              | 6          | Check the JP1 user specified by the <code>jp1User</code> argument to see if: <ul style="list-style-type: none"> <li>• The user is mapped with the OS user on the execution host.</li> <li>• The server hosts with user mapping contain the JP1/IM hosts.</li> </ul> |
| 7   | Internal error                                       | 255        | Use the data collection tool to collect data and contact the system administrator.                                                                                                                                                                                  |

#:

When a timeout occurs, the process of the command currently running is terminated.

#### Note

If UAC is enabled on the execution host, the primary user of the JP1 user specified for `jp1User` must be the built-in Administrator user.

### 4.5.11 jp1Imdd.getPluginConfDirPath

This method returns the absolute path to the parent directory of the directory that stores plug-in definition files as string type. The following table shows the details of the `jp1Imdd.getPluginConfDirPath` method.

#### Method name

```
String jp1Imdd.getPluginConfDirPath (pluginName)
```

#### Parameters

`pluginName`  
String that indicates the name of the plug-in  
Example: `jp1pfm`

#### Return values

The method returns a string representing the absolute path to the directory under which the plug-in definition files are stored.

When null is specified in the parameter or in the event of an internal error, null is returned.

Example: In physical hosts of Windows.

`Manager-path\conf\imdd\plugin\jp1pfm`

#### Exception

None

### 4.5.12 jp1Imdd.getVersion

This method returns the version of JP1/IM as string type. The following table shows the details of the `jp1Imdd.getVersion` method.

#### Method name

String jplImdd.getVersion ()

#### Parameters

None

#### Return values

Returns the version of the product in *VV-RR* or *VV-RR-SS* format.

For example, the returned value is 12-00 which omits SS when the version of the product is 12-00, and the returned value is 12-00-02 when the version of the product is 12-00-02.

The method returns the same value as `productVersion` of the version information acquisition API. For details, see [5.12.1 Version information acquisition](#).

#### Exception

None

#### Example

To make a user-created plug-in downward compatible, check the version of JP1/IM as shown below to branch out the process.

```
var im2Version = null;

if(typeof jplImdd.getVersion == "function") {
    im2Version = jplImdd.getVersion();
} else {
    im2Version = "12-00";
}

switch(im2Version) {
    case "12-00":
        // Operations for 12-00
        break;
    case "12-10":
        // Operations for 12-10
        break;
}
```

### 4.5.13 jp1EmService.getEvent

This method retrieves events related to an IM management node from the integrated monitoring database. Specifically, a list of events matching the conditions specified by the parameters is retrieved.

If the JP1 user who specified this method does not have the permission to view the events in question, the user cannot retrieve them. In this case, no error message is output.

The range of events that can be retrieved depends on the JP1 resource group settings and the event receiver filter settings in JP1/IM - Manager. For details about the conditions under which a user may be able to view certain events, see information regarding the events that can be displayed in the event view when an IM management node is selected in [3.5.1 Structure of the IM management node](#) in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

This method cannot be called from the `__eventGet` method provided by product plug-ins or from the method called by the `__eventGet` method.

The details of the `jplEmService.getEvent` method are provided below.

#### Method name

```
Object jplEmService.getEvent(String sid, Object filter, String direction,  
String since, int count, String[] attrs, int[] statusFilter, boolean  
consolidateEvent, int searchCount, String lang, String jplUser,  
String jplToken)
```

#### Parameters

`sid`

Specify the tree SID of an IM management node. A list of events issued by the specified IM management node is retrieved.

If you specify `null` or an empty string, it is assumed that all systems (`_ROOT_AllSystems`) are specified. If you specify `null` or an empty string without any IM management nodes having been set up, an empty list of events is returned.

`filter`

Specify an event search condition object.

This method searches the integrated monitoring database for events that meet the specified event search conditions. For details about the event search condition object, see [7.2.1 \(3\) Event search condition object](#). If you specify a single-byte space as any of the attribute values, it is assumed that `%20` is specified.

You can narrow down the events specified with `sid` to those that meet the event search conditions specified with `filter`. If you do not need to narrow down the retrieved events, specify `null` for `filter`.

When there is no pass-conditions group that contains both an event search condition in which `key` is set to `B.TIME` (registered time) and `ope` is set to `TRANGE` (time) and an event search condition in which `key` is set to `B.ARRIVEDTIME` (arrived time) and `ope` is set to `TRANGE` (time)<sup>#</sup>, it is assumed that one of the pass-conditions groups is specified as follows:

```
{ "key": "B.TIME", "ope": "TRANGE", "val": ["1-day-before-current-time", "curr  
ent-time"] }
```

<sup>#</sup>: This includes specifying `null` for `filter`.

In an event search condition in which `key` is set to `B.ID` (event ID), the digits of the value specified for `val` are automatically padded with zeros.

`direction`

Specify the direction in which to search for events.

Specify `past` to search for events that occurred before the specified event and `future` to search for events that occurred after the specified event. If you specify `null` or an empty string, it is assumed that `past` is specified.

`since`

Specify the SID of the JP1 event that serves as a starting point for the event search. The method searches for events that occurred either before or after the JP1 event corresponding to the specified SID. Note that the JP1 event corresponding to the specified SID is not included in the search. If you specify `null` or an empty string, the integrated monitoring database is searched from either the beginning or end depending on the setting specified for `direction`. For details about the SIDs of JP1 events, see [7.2.1 \(1\) Event information object](#).

`count`

Specify the maximum number of events to be retrieved in the range from 1 to 2,000.

`attrs`

Specify an array of event attributes to be retrieved.

Example:

```
"attrs":["B.ID","B.MESSAGE",...]
```

The attributes specified for `attrs` are retrieved in user-specified order. When `null` is specified, attributes are acquired differently depending on the type of JP1 events specified.

- When consolidation start events are specified

All the attribute values that can be output by the event report output function are retrieved first. Afterwards, the attributes listed in the table under *Event attributes of the consolidation start event* in [7.2.1 \(1\) Event information object](#) are retrieved.

- When events other than consolidation start events are specified

All the attribute values that can be output by the event report output function are retrieved. The specifiable event attributes include all the attributes that can be output by the event report output function and the attributes listed in the table under *Event attributes of the consolidation start event* in [7.2.1 \(1\) Event information object](#).

For details about the event report output function, see [4.15.2 Saving event information in the integrated monitoring database \(CSV report\)](#) in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

#### `statusFilter`

To narrow down the events to those whose nodes match the specified status, specify status values by using the `int` array.

Example: To retrieve only those events whose node status is 30 and 40

```
"statusFilter":[30,40]
```

For details about the node status codes, see [5.8.5 IM management node status acquisition](#). If you do not need to narrow down events, specify `null`.

#### `consolidateEvent`

When repeated events have been consolidated on the Intelligent Integrated Management Base, specify whether you want the consolidated repeated events to be returned. To prevent repeated events from being returned, specify `true`.

- `true`

When the display of repeated events is suppressed on the Intelligent Integrated Management Base, only the consolidation start events are returned. Repeated events that come after each consolidation start event are not returned.

- `false`

Repeated events are returned regardless of whether the display of repeated events is suppressed on the Intelligent Integrated Management Base.

#### `searchCount`

Specify the maximum number of times a search for events can be repeated in the range from 0 to 120,000.

A total of 100 events mapped to the IM management node specified by the `sid` parameter are searched through, starting from the event specified by the `since` parameter and proceeding in the direction specified by the `direction` parameter.

When the number of events specified by the `count` parameter cannot be retrieved due to an event receiver filter or other restrictions, the search is repeated, that is, the next 100 events are searched through. The maximum number of times the search for events can be repeated is what you need to specify for this parameter.

When the specified maximum limit is reached, the search is discontinued, and a list of all events retrieved before the discontinuation of the search is output along with the `KAJY32010-W` message. If you specify nothing or 0 for this parameter, there is no limit to the number of times a search can be repeated.

lang

Specify the language of the message. You can specify `ja`, `ja-JP`, or `en`. If you specify any other values, it is assumed that `en` is specified. For details, see *Language conventions of user-created plug-ins* in [4.4 Methods implemented in the plug-in](#).

jplUser

By using a string of 1 to 31 bytes, specify the name of a JP1 user who has one of the following JP1 permission levels. Only the events that the specified JP1 user has the permission to view are retrieved.

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

jplToken

Specify a JP1 authentication token for the JP1 user specified for `jplUser`.

#### Return values

After successful retrieval of events, an object storing event information is returned. The following table describes the keys and their values stored in the object after successful retrieval of events:

| No. | Key       | Value                                                                                                                                                                                                                                                                                                                                     |
|-----|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | eventData | Returns an array of event information objects that represents a list of retrieved events. For details about event information objects, see <a href="#">7.2.1 (1) Event information object</a> . When there is no event to be returned, a zero-length array is returned.                                                                   |
| 2   | messageId | Returns the message ID of a temporary error message generated during an event search. Either KAJY32005-W or KAJY32010-W is returned. When there is no message to be provided, <code>null</code> is specified. For details about messages, see the <i>JP1/Integrated Management 3 - Manager Messages</i> .                                 |
| 3   | message   | Returns the body of a temporary error message generated during an event search. When there is no message to be provided, <code>null</code> is specified.                                                                                                                                                                                  |
| 4   | beginSid  | Returns the SID of a JP1 event that is right next to (that is, immediately before or after, depending on the specified direction of event search) the event that has been specified by the <code>since</code> parameter as the starting point for the event search. When there are no JP1 events to be searched for, this key is omitted. |
| 5   | endSid    | Returns the SID of the JP1 event located at the end position of the event search. When the event search is discontinued, the SID of the JP1 event where the search was discontinued is returned. When there are no JP1 events to be searched for, this key is omitted.                                                                    |

The following table describes the keys and their values stored in the object after a failed attempt to retrieve events:

| No. | Key            | Value                                                                                                                                                                                                                                                                                                                                                         |
|-----|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | errorMessage   | An error message. When any of the arguments are invalid, the KAJY22043-E error message is set. If this method is executed while the JP1/IM3 - Manager service is stopped, the KAJY32000-E message is set.<br>For details about the error messages set in all the other cases, see the table under <i>Status codes</i> in <a href="#">5.6.1 Event search</a> . |
| 2   | errorMessageId | Returns the ID of the error message.                                                                                                                                                                                                                                                                                                                          |

In methods of a product plug-in that calls this method, consider error messages and error processing based on the specifications of the plug-in, according to the value of the key `errorMessageId`.

Output the key `errorMessage` to the internal log of the product plug-in for use in troubleshooting it.

#### Exception

None

## 4.5.14 jp1SimtService.getLink

This method retrieves link information.

This method cannot be called from the `__eventGet` method provided by product plug-ins or from the method called by the `__eventGet` method.

The details of the `jp1SimtService.getLink` method are provided below.

### Method name

```
Object jp1SimtService.getLink(String type, String sid, int fromLayerCount,
int toLayerCount, int countPerLayer, int linkCount, String lang, String
jp1User, String jp1Token)
```

### Parameters

`type`

Of the types of link information supported by the system, specify the one corresponding to the link information you want to retrieve. If you specify `null` or an empty string, applicable link information is returned regardless of link information type.

`type` describes a grouping of relations that have the same meaning. On the **Related node** tab in the Integrated Operation Viewer window, you can filter relations to display only those belonging to a specific type.

For relations within a JP1/IM product or between a JP1/IM product and another product, the following types are used. In addition to these types, the use of user-specified types is also allowed.

- `rootJobnetExecutionOrder`: Relation of the execution order of root jobnets
- `managerAgent`: Relation between the manager and agent of a JP1 product
- `rootJobnetAgent`: Relation between a root jobnet and an AJS agent
- `sameNode`: Relation between nodes with the same name
- `L2Connection`: Relation between layer-2 connection lines managed by JP1/NNMi
- `Infrastructure`: Relation between infrastructure resources managed by JP1/OA
- `monitoringConfiguration`: Relation between a product and a monitoring target in a monitoring product configuration

`sid`

Specify the SID of the node to be processed. Information regarding the nodes preceding and succeeding the specified node is returned. If you specify `null` or an empty string, link information on all nodes is returned.

`fromLayerCount`

Specify the maximum number of preceding node layers to be retrieved in the range from 0 to 2147483647. If you specify `null` or an empty string for `sid`, the value specified for the `fromLayerCount` parameter is ignored.

`toLayerCount`

Specify the maximum number of succeeding node layers to be retrieved in the range from 0 to 2147483647. If you specify `null` or an empty string for `sid`, the value specified for the `toLayerCount` parameter is ignored.

`countPerLayer`

Specify the maximum number of nodes to be retrieved per node layer in the range from 1 to 2147483647. If you specify `null` or an empty string for `sid`, the value specified for this argument is ignored.

linkCount

Specify the maximum number of links to be retrieved in the range from 1 to 2147483647. If you specify `null` or an empty string for `sid`, the value specified for the `linkCount` parameter is ignored.

lang

Specify the language of the message. You can specify `ja`, `ja-JP`, or `en`. If you specify any other values, it is assumed that `en` is specified. For details, see *Language conventions of user-created plug-ins* in [4.4 Methods implemented in the plug-in](#).

jp1User

By using a string of 1 to 31 bytes, specify the name of a JP1 user who has one of the following JP1 permission levels:

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

jp1Token

Specify a JP1 authentication token for the JP1 user specified for `jp1User`.

#### Return values

After successful retrieval of link information, an object storing link information is returned. The following table describes the keys and their values stored in the object:

| No. | Key                 |               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----|---------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | links               |               | Returns an array of retrieved link information. For details about the array of link information, see <i>IM management node link definition file (imdd_nodeLink_def.conf)</i> in <i>Chapter 2. Definition Files</i> .                                                                                                                                                                                                                                                                                                                                      |
| 2   | exceedCountDetected |               | Indicates whether it has been detected that the value specified for the parameter has exceeded the maximum limit.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 3   |                     | countPerLayer | Indicates whether it has been detected that the maximum number of nodes per layer has been exceeded.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 4   |                     | layerinteger  | Replaces <i>integer</i> with the number assigned to each layer. 0 is assigned to the layer specified for <code>sid</code> , with the number assigned to the layers succeeding it incremented starting from +1, and that assigned to the layers preceding it decremented starting from -1. In this way, this key indicates for all layers returned whether it has been detected that the maximum number of nodes allowed per layer has been exceeded. <ul style="list-style-type: none"><li>• true<br/>Detected</li><li>• false<br/>Not detected</li></ul> |
| 5   |                     | linkCount     | Indicates whether it has been detected that the maximum number of links allowed has been exceeded. <ul style="list-style-type: none"><li>• true<br/>Detected</li><li>• false<br/>Not detected</li></ul>                                                                                                                                                                                                                                                                                                                                                   |
| 6   | messageId           |               | A message ID. When there is no message to be provided, <code>null</code> is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 7   | message             |               | The body of a message. When there is no message to be provided, <code>null</code> is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

The following table describes the keys and their values stored in the object after a failed attempt to retrieve link information:

| No. | Key                         | Value                                                                                                                                                                                                                                                   |
|-----|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>errorMessage</code>   | An error message. When any of the arguments is invalid, the KAJY22043-E error message is output.<br>For details about the error messages output in all the other cases, see the table under <i>Status codes</i> in <a href="#">5.6.1 Event search</a> . |
| 2   | <code>errorMessageId</code> | Returns the ID of the error message.                                                                                                                                                                                                                    |

In methods of a product plug-in that calls this method, consider error messages and error processing based on the specifications of the plug-in, according to the value of the key `errorMessageId`.

Output the key `errorMessage` to the internal log of the product plug-in for use in troubleshooting it.

Exception

None

### 4.5.15 jp1EmService.changeEventStatus

This method changes the event status. When the specified JP1 user does not have the permission to view the specified events, an error occurs. When the specified user does not have the permission to operate the specified events, the user is not allowed to operate the events. For details about the conditions under which a JP1 user may be able to view JP1 events, see information regarding the events a JP1 user can display in the event view after selecting an IM management node in [3.5.1 Structure of the IM management node](#) in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

This method cannot be called from the `__eventGet` method provided by product plug-ins or from the method called by the `__eventGet` method.

The details of the `jp1EmService.changeEventStatus` method are provided below.

Method name

```
Object jp1EmService.changeEventStatus(int dealt, String[] sid, String lang,
String jp1User, String jp1Token)
```

Parameters

`dealt`

Specify one of the following values to indicate the event status after the change:

- 0 (Unprocessed)
- 1 (Processed)
- 2 (Processing)
- 3 (Held)

`sid`

Specify an array of SIDs corresponding to the JP1 events whose status you want to retrieve. For details about the SIDs of JP1 events, see [7.2.1 \(1\) Event information object](#). You can specify a maximum of 2,000 SIDs of JP1 events.

lang

Specify the language of the message. You can specify `ja`, `ja-JP`, or `en`. If you specify any other values, it is assumed that `en` is specified. For details, see *Language conventions of user-created plug-ins* in [4.4 Methods implemented in the plug-in](#).

jp1User

By using a string of 1 to 31 bytes, specify the name of a JP1 user who has one of the following JP1 permission levels:

- `JP1_Console_Admin`
- `JP1_Console_Operator`

jp1Token

Specify a JP1 authentication token for the JP1 user specified for `jp1User`.

#### Return values

After changes are made successfully to the event status, an object storing event information is returned. The following table describes the keys and their values stored in the object:

| No. | Key                    | Value                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>eventData</code> | Returns an array of event information objects representing a list of events whose statuses have been changed. For details about the event information objects, see <a href="#">7.2.1 (1) Event information object</a> . When there are any events that the specified user did not have the sufficient permission to operate, only those events that the user succeeded in operating are returned. |
| 2   | <code>messageId</code> | Returns the message ID of a temporary error message generated during an event search. When there is no message to be provided, <code>null</code> is specified.                                                                                                                                                                                                                                    |

The following table describes the keys and their values stored in the object after a failed attempt to change the event status:

| No. | Key                         | Value                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>errorMessage</code>   | An error message. When any of the arguments is invalid, the <code>KAJY22043-E</code> error message is set. If this method is executed while the JP1/IM3 - Manager service is stopped, the <code>KAJY32100-E</code> message is set.<br>For details about the error messages set in all the other cases, see the table under <i>Status codes</i> in <a href="#">5.6.1 Event search</a> . |
| 2   | <code>errorMessageId</code> | Returns the ID of the error message.                                                                                                                                                                                                                                                                                                                                                   |

In methods of a product plug-in that calls this method, consider error messages and error processing based on the specifications of the plug-in, according to the value of the key `errorMessageId`.

Output the key `errorMessage` to the internal log of the product plug-in for use in troubleshooting it.

#### Exception

None

## 4.5.16 jp1SimtService.getTreeSid

This method retrieves the tree SID corresponding to the specified configuration information SID.

This method cannot be called from the `__eventGet` method provided by product plug-ins or from the method called by the `__eventGet` method.

The details of the `jp1SimtService.getTreeSid` method are provided below.

#### Method name

`String jplSimtService.getTreeSid(String sid)`

#### Parameters

`sid`

Specify the configuration information SID.

#### Return values

A tree SID is returned.

When `null` is specified for `sid` or when there is no tree SID corresponding to the specified configuration information SID, `null` is returned.

#### Exception

None

## 4.5.17 jplTrendDataService.getTrendData

This method retrieves trend data (time series data) from the trend data management DB.

Here are the details of the `jplTrendDataService.getTrendData` method:

#### Method name

`Object jplTrendDataService.getTrendData(String jpluser, String sid, String promQLQuery, String starttime, String endtime, String step)`

#### Parameters

`jpluser`

Specify the JP1 user name in the range of 1~31 bytes.

If the SID specified by the `sid` argument specifies a SID for which the JP1 user specified by the `jpluser` argument does not have reference authority\*, 0 data records are returned.

Note: This applies when a JP1 resource group with one of the following JP1 authorization levels is not set to the SID specified in the argument `sid` among the JP1 resource groups set for the JP1 user.

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

`sid`

Specifies the SID for the configuration information.

If the replacement string `"$jplim_TrendData_labels"` is included in PromQL expression specified by the argument `promQLQuery`, it is replaced by value of the `jplim_TrendData_labels` that is set in SID of the configuration information specified by the argument `sid` and passed to the trend data management service.

`promQLQuery`

Specify the filter conditions for trend data with PromQL statements.

For details about PromQL expression that can be specified, see 2.7.4(7) *About PromQL* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

`starttime`

Specifies the start time for fetching trend data in seconds elapsed since January 1, 1970 00:00:00 (UNIX epoch). You cannot specify a time (negative value) before 0:00:00 a.m. on January 1, 1970.

endtime

Specifies the end time for obtaining trend data in seconds elapsed since January 1, 1970 00:00:00 (UNIX epoch). You cannot specify a time (negative value) before 0:00:00 a.m. on January 1, 1970.

step

Specify the interval between getting trend data in seconds.

#### Return values

If the trend data acquisition is successful, the trend data object containing the trend data information is returned. For details on the format of trend data objects, see [7.2.3\(1\) Trend Data Object](#).

If trend data fails to be retrieved, the keys and values stored in the object are shown below.

| Key            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| errorMessage   | Error message. <ul style="list-style-type: none"><li>• If the jp1user argument is invalid, the message KAJY22043-E is set.</li><li>• If the sid argument is invalid, a KAJY62003-E error message is set.</li><li>• If the port number of the Trend Data Management Service fails to be obtained, the message KAJY62004-E is set.</li><li>• If communication with the Trend Data Management Service fails, the message KAJY62000-E is set.</li><li>• If the Trend Data Management Service returns an error, the message KAJY62002-E is set.</li><li>• If the SID of the configuration information managed by the subordinate manager is specified and the connection to the intelligent integrated management infrastructure of the subordinate manager fails, the message KAJY00027-E is set.</li><li>• If the SID of the configuration information managed by the subordinate manager is specified and an error occurs in the processing of the intelligent integrated management infrastructure of the subordinate manager, the message KAJY00029-E is set.</li></ul> |
| errorMessageId | Returns the ID of the error message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

The method of the user-created plug-in that calls this method determines the error by the presence or absence of the value of the key `errorMessageId`, and depending on the contents of the value, consider error messages and error handling based on the plug-in specifications.

Output the value of the key `errorMessage` to the internal log of the plug-in and use it for plug-in failure investigation.

#### Exception

None

## 4.5.18 jp1TrendDataService.getLabelList

This method retrieves a list of time series of label set Match to the parameter-specified criteria from Trend data Management Database of the respective manager.

#### Method name

```
Object jp1TrendDataService.getLabelList(String host, String[] match, String starttime, String endtime, String jp1User)
```

#### Parameters

host

Specify host name of JP1/IM - Manager, from 1 to 255.

match

Specify the filter criteria for the label set to retrieve from Trend data Management Database.

More than one condition can be specified as an array. If specified, an OR condition is set. You can specify up to three conditions.

The criteria can be a metric. You can also add a comma-separated list enclosed in {} to specify a condition that compares a label with a label value enclosed in '. The following shows the operators and specification examples of comparison conditions.

- =: Match the specified text
- !=: Does not match the specified text.
- =~: Regex match to the specified string
- !~: Regex does not match on the specified string

(Example of specification)

- When creating IM management node for various Exporter  
When you retrieve a up metric label-set, you specify up.
- To create IM management node for Yet another cloudwatch exporter  
When retrieving a label set that starts with aws\_ in the \_\_name\_\_ label, specify {\_\_name\_\_=~'aws\_.\*'}.
- To create IM management node for Fluentd  
When retrieving the fluentd\_logtrap\_running label set, specify the fluentd\_logtrap\_running.

starttime

Specifies the starting time for retrieving the list of label sets, in seconds since UTC 1970 January 1 00:00:00 (UNIX epoch). The time before midnight 0:0:0 on January 1, 1970 (minus Value) cannot be specified.

endtime

Specifies the ending time for retrieving the list of label sets, in seconds since UTC 1970 January 1 00:00:00 (UNIX epoch). The time before midnight 0:0:0 on January 1, 1970 (minus Value) cannot be specified.

jplUser

Specify JP1 user name with the following JP1 Permissions level in the range of 1~31 bytes.

- JP1\_Console\_Admin

#### Return values

If the list of label sets is successfully retrieved, the list of label sets is returned. For the format of the list of label sets, see [7.2.3\(2\) Label Set List Object](#).

The following table lists the keys and value that are stored in the object when retrieving the list of label sets fails.

| Key            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| errorMessage   | Error message. <ul style="list-style-type: none"><li>• If the Trend Data Management Service fails to retrieve Port number, KAJY62004-E's message is Setup.</li><li>• If communication with the Trend Data Management Service fails, KAJY62000-E's message is Setup.</li><li>• If the Trend Data Management Service returns Error, KAJY62005-E's message is Setup.</li><li>• If the specified host fails to connect to Intelligent Integrated Management Base, KAJY00027-E's message is Setup.</li><li>• If Intelligent Integrated Management Base operation on the specified host fails, KAJY00029-E's message is Setup.</li></ul> |
| errorMessageId | Returns id of the error message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

For user-created plug-in method that invokes this method, determine error with or without value of `errorMessageId` key. Depending on the content of value, consider error messages or error handling based on the plug-in specification.

The key `errorMessage` value is output to the plug-in's internal log. It can be used to investigate plug-in failures.

Exception

None

## 4.6 File name and the storage location of the user-created plug-in

---

You can specify any given name for the file name of the user-created plug-in. The name must follow the rules below.

- Characters available for the file name: Alphanumeric characters
- Extension: `.js` at all times
- The following file names are not available. The file name is case insensitive.  
File name that starts with `jpl` or `hitachi`

The user-created plug-in should be located in the directory with the same name as the file name of the plug-in. In a single directory, you can put only one file with the same name as the directory.

The following shows an example of creating the user-created plug-in named `userPlugin.js`.

In Windows:

On a physical host:

*Manager-path*\plugin\imdd\userPlugin\

On a logical host:

*shared-folder*\jplimm\plugin\imdd\userPlugin\

In UNIX:

On a physical host:

*/etc/opt/jplimm/plugin/imdd/userPlugin/*

On a logical host:

*shared-directory*/jplimm/plugin/imdd/userPlugin/

If you create a directory named `user` as a storage location for a plug-in, the `user` directory can contain some user-created plug-ins with a given file name.

### 4.6.1 Definition files used by user-created plug-ins

The following shows where the definition files used by user-created plug-ins are located.

In Windows:

On a physical host:

*Manager-path*\conf\imdd\plugin\*product-name*#\

On a logical host:

*shared-folder*\jplimm\conf\imdd\plugin\*product-name*#\

In UNIX:

On a physical host:

*/etc/opt/jplimm/conf//imdd/plugin/product-name#/*

On a logical host:

*shared-directory*/jplimm/conf/imdd/plugin/*product-name*#/

#: *product-name* can be:

- In JP1/AJS: *jp1ajs*
- In JP1/PFM: *jp1pfm*

File

- *file-name.extension*
- *file-name.extension.model*

Include *file-name.extension.model* and create a file with the name of *file-name.extension* during installation.  
During upgrade installation, only *file-name.extension.model* is overwritten.

## 4.7 Applying changes made to user-created plug-ins

---

When you make changes to user-created plug-ins, you have to restart the JP1/IM3 - Manager service.

# 5

## API

This chapter describes the APIs provided by JP1/IM - Manager (Intelligent Integrated Management Base).

## 5.1 List of APIs

The following table lists APIs that can be used with the user-created plug-in of JP1/IM.

Table 5–1: List of APIs of the user-created plug-in (API related to JP1/IM - Manager)

| Category                 | API name                                              | Description                                                                                                    |
|--------------------------|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| User authentication      | Login                                                 | Logs in to the Intelligent Integrated Management Base.                                                         |
|                          | Logout                                                | Logs out from the Intelligent Integrated Management Base.                                                      |
|                          | Initial secret issue                                  | Issue initial secret.                                                                                          |
|                          | IM Client secret delete                               | Delete IM client secret that you have added to the database.                                                   |
|                          | IM Client secret issue                                | Issue IM client secret and add it in the database.                                                             |
|                          | IM Client list acquisition                            | Retrieve a list of added IM client IDs.                                                                        |
| Link information         | Link information acquisition                          | Gets the link information that represents order relationships between objects.                                 |
|                          | Link type list acquisition                            | Gets the list of types of link information.                                                                    |
| Event management         | Event search                                          | Searches the integrated monitoring database for events based on specified conditions.                          |
|                          | Event detailed information acquisition                | Gets the details of a specified event.                                                                         |
|                          | Event status change                                   | Changes the event status of specified events.                                                                  |
|                          | Event generation                                      | Generates the specified event.                                                                                 |
|                          | JP1 Event converter                                   | This function converts event data reported from an external system to JP1 events and issues them.              |
| Performance information  | Plug-in processing execution                          | Executes plug-in operations for performance information.                                                       |
| System status monitoring | IM management node related information generation     | Obtains the system configuration information and generates a configuration management tree File.               |
|                          | IM management node related information reflection     | Reflect configuration management tree file in Intelligent Integrated Management Base.                          |
|                          | IM management node information acquisition            | Gets the information of IM management nodes collected from JP1/AJS3, JP1/PFM, JP1/IM, JP1/Base, and others.    |
|                          | Configuration management tree information acquisition | Gets the configuration information of IM management nodes (management groups or management objects) as a tree. |
|                          | IM management node status acquisition                 | Gets the status information of all IM management nodes (management groups or management objects).              |
|                          | Suggestion mapping information acquisition            | Gets information regarding the mapping between IM management nodes and suggestion IDs.                         |
| Proxy                    | Proxy credential setup                                | Sets the authentication user and password of the proxy server.                                                 |
| Linked product           | URL information acquisition                           | Gets the URL to start a linked product configured in an IM management node.                                    |
| Trend                    | Metric list acquisition                               | Gets the list of metrics for the specified SID.                                                                |
|                          | Time-series data acquisition                          | Gets time-series data for the specified SID.                                                                   |
|                          | Write Trend Data                                      | Writes trend data to Trend data Management Database. The data to be written can be specified in JSON format.   |

| Category                                    | API name                                                      | Description                                                                                                                                                                       |
|---------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                             | <a href="#">Delete Trend Data</a>                             | Deletes trend data stored in Trend data Management Database by Prometheus and Fluentd of the specified host including user-defined Prometheus and your own Fluentd.               |
| Information management                      | <a href="#">Version information acquisition</a>               | Gets the JP1/IM version and REST API versions.                                                                                                                                    |
| Suggestion                                  | <a href="#">Previous execution history acquisition</a>        | Gets a history of previously executed response actions.                                                                                                                           |
|                                             | <a href="#">Response action suggestion</a>                    | Suggests response actions appropriate to the system status.                                                                                                                       |
|                                             | <a href="#">Response action execution</a>                     | Executes a response action.                                                                                                                                                       |
| OpenID authentication                       | <a href="#">Single sign-on mapping definition application</a> | Applies the mapping information defined in the single sign-on mapping definition file ( <code>imdd_sso_mapping.properties</code> ) to the Intelligent Integrated Management Base. |
| Distribution                                | <a href="#">Get distribution (File download)</a>              | Downloads the distribution specified in the request line (File).                                                                                                                  |
| Execute for Auto/<br>Manual Response Action | <a href="#">Obtain execution result of Response Action</a>    | Get Execute of Response Action.                                                                                                                                                   |
|                                             | <a href="#">Manual execution of Response Action</a>           | Response Action(manual) is performed.                                                                                                                                             |
|                                             | <a href="#">Convert event-takeover info</a>                   | Event information is inherited.                                                                                                                                                   |
| Definition<br>file Manipulation             | <a href="#">Get definition file list</a>                      | Retrieves a list of definition file.                                                                                                                                              |
|                                             | <a href="#">Get definition file</a>                           | Retrieve the definition file.                                                                                                                                                     |
|                                             | <a href="#">Delete definition file</a>                        | Delete the definition file.                                                                                                                                                       |

| Lower manager<br>Info Management            | <a href="#">Retrieve lower manager info list</a>              | Retrieve the base and relay manager under the control of Integrated manager.                                                                                                      |
|                                             | <a href="#">Add lower manager info</a>                        | Add the base or relay manager under the information of Integrated manager.                                                                                                        |
|                                             | <a href="#">Delete lower manager info</a>                     | Delete the base or relay manager under the control of Integrated manager.                                                                                                         |
| Dashboard Definition                        | <a href="#">Get dashboard definition</a>                      | Get the dashboard definition.                                                                                                                                                     |
|                                             | <a href="#">Get dashboard definitions list</a>                | Get a list of dashboard definitions.                                                                                                                                              |
|                                             | <a href="#">Add dashboard definition</a>                      | Add a dashboard definition.                                                                                                                                                       |
|                                             | <a href="#">Delete dashboard definition</a>                   | Delete the dashboard definition.                                                                                                                                                  |

Table 5–2: List of APIs of the user-created plug-in (API related to JP1/IM - Agent)

| Category                                          | API name <sup>#</sup>                              | Description                                                                                 |
|---------------------------------------------------|----------------------------------------------------|---------------------------------------------------------------------------------------------|
| Prometheus server                                 | <a href="#">Reload Prometheus server</a>           | Refreshes Prometheus server definition file and reflects it in Prometheus server operation. |
|                                                   | <a href="#">Prometheus server health check</a>     | Performs a health check of Prometheus server.<br>The status code always returns 200.        |
| Alertmanager                                      | <a href="#">Reload Alertmanager</a>                | Refreshes Alertmanager definition file and reflects it in Alertmanager operation.           |
|                                                   | <a href="#">Alertmanager health check</a>          | Performs a health check of Alertmanager.<br>The status code always returns 200.             |
|                                                   | <a href="#">Get silence list of Alertmanager</a>   | Retrieves a list of silence created in Alertmanager in JSON format.                         |
|                                                   | <a href="#">Silence creation of Alertmanager</a>   | Pass JSON form of silence's setting and create a silence in Alertmanager.                   |
|                                                   | <a href="#">Silence Revocation of Alertmanager</a> | Revokes (expires immediately) silence created in Alertmanager.                              |
|                                                   | <a href="#">Get silence of Alertmanager</a>        | Retrieves the specified silence in JSON format.                                             |
| Blackbox exporter                                 | <a href="#">Reload Blackbox exporter</a>           | Refreshes Blackbox exporter definition file and reflects it in Blackbox exporter operation. |
| API for scrape of Exporter used by JP1/IM - Agent |                                                    | Execute scrape of Exporter for which you want to scrape Prometheus server.                  |

#

API do not have access-control functions. You can limit the source hosts of API by specifying a connectable IP address for the ports that the firewall allows.

## 5.2 API common specifications

Monitored information collected by JP1/IM - Manager (Intelligent Integrated Management Base) can be accessed by using API via http(s).

The API provided with the Intelligent Integrated Management Base is based on the REST (Representational State Transfer) architecture style.

### 5.2.1 Communication methods

The API uses the communication protocols and the port number described below. For API communication, you can use the http or https protocol.

Communication protocols  
HTTP, HTTPS

Port number  
20703

For details on the port number, see *Intelligent Integrated Management Base definition file (imdd.properties)* in 2. Definition Files.

### 5.2.2 Input/Output format

The JSON format is used for the data of API requests and responses. The data is encoded in UTF-8.

### 5.2.3 Request format

To access the functionality provided by the Intelligent Integrated Management Base through the API, compose a request as follows:

```
method /application/component/apiVersion/resourceId?query httpVersion
requestHeader

messageBody
```

The following table describes how to compose a request.

Table 5–3: Request format in detail

| Item   | Description                                                                                                                                                                                                                                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| method | <p>Specify how to operate the resource. Select a method appropriate to the API processing. The API supports the following methods:</p> <ul style="list-style-type: none"><li>GET<br/>Gets a list of resources or their information.</li><li>POST<br/>Enables the Intelligent Integrated Management Base to process the resource.</li><li>PUT</li></ul> |

| Item                 | Description                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <p>Updates a list of resources or their information.</p> <ul style="list-style-type: none"> <li>DELETE</li> </ul> <p>Deletes a list of resources or their information.</p> <p>For details on the method you specify, see <i>Format</i> for each API.</p>                                                                                                                                |
| <i>application</i>   | The name of the application that provides the API. Always set this to <code>im</code> .                                                                                                                                                                                                                                                                                                 |
| <i>component</i>     | <p>The component name of the API.</p> <p>Specify <code>api</code> for APIs used by the user, and <code>api_system</code> for APIs used by the system. Note that the APIs that can be used for <a href="#">5.2.8(4) Authentication through client secret information added to a REST API (Basic authentication)</a> are limited to APIs with component name <code>api_system</code>.</p> |
| <i>apiVersion</i>    | The API version. Always set this to <code>v1</code> .                                                                                                                                                                                                                                                                                                                                   |
| <i>resourceId</i>    | The functions provided by the Intelligent Integrated Management Base can be identified by specifying a resource identifier in an API request. Specify the identifier of a function that you want to run. For details, see <a href="#">Table 5-4 Resource identifiers</a> .                                                                                                              |
| <i>query</i>         | The query string. You can add search conditions to a request to filter or sort records to be returned in a response.                                                                                                                                                                                                                                                                    |
| <i>httpVersion</i>   | The version of the communication protocol that the API uses. Always set this to <code>HTTP/1.1</code> .                                                                                                                                                                                                                                                                                 |
| <i>requestHeader</i> | Specify the data format, language code, and other settings of the response. For details, see <a href="#">Table 5-5 Request headers</a> .                                                                                                                                                                                                                                                |
| <i>messageBody</i>   | <p>Specify the data format of the message body.</p> <p>You can use the JSON format. The data is encoded in UTF-8.</p>                                                                                                                                                                                                                                                                   |

Table 5–4: Resource identifiers

| Resource identifier     | Resource to be accessed                                     |
|-------------------------|-------------------------------------------------------------|
| <code>nodes</code>      | Management nodes                                            |
| <code>status</code>     | Status information                                          |
| <code>links</code>      | Link information (relationship of jobnets or others)        |
| <code>events</code>     | JP1 events                                                  |
| <code>actions</code>    | Plug-in actions (getting performance information or others) |
| <code>login</code>      | Login token or permissions                                  |
| <code>proxyUsers</code> | Proxy user information                                      |

Table 5–5: Request headers

| Header                       | Description                                                                                                                                                                                                                                                                                                                     | Default value   | Required/Optional |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-------------------|
| <code>Authorization</code>   | <p>Specify the authentication information for the API. This must be specified if permission is required for the user to invoke the API.</p> <p>For details on the authentication information and how to set the authentication information to invoke the REST API, see <a href="#">Authentication methods for REST API</a>.</p> | None            | Required          |
| <code>Accept-Language</code> | <p>Specify the language you want to use in response data with one of the following language codes:</p> <ul style="list-style-type: none"> <li><code>ja</code> or <code>ja-JP</code></li> </ul> <p>Japanese</p>                                                                                                                  | <code>en</code> | Optional          |

| Header         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Default value        | Required/<br>Optional                                                                                               |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|---------------------------------------------------------------------------------------------------------------------|

| Content-Type   | <p>The data format of the request message body.</p> <p>Omitting this header when using the POST method or specifying an invalid value results in the status code 415 to be returned.</p> <p>If you use the POST method and there is no message body, or if you use the GET method and you specify a value other than application/json, the status code 200 is returned.</p>                                                                                                                                                                                                                                                                                                                     | None                 | Required                                                                                                            |
| Content-Length | <p>Specify the length of the message body in the request.</p> <ul style="list-style-type: none"> <li>For the GET method:<br/>Omit this header or specify 0.</li> <li>For the POST method:<br/>Specify the size (in bytes) of the request body. This must be specified as a decimal number.</li> </ul> <p>Omitting this header when using the POST method is results in the status code 411 to be returned.</p> <p>If you use the POST method and you have specified the request body of which the size exceeds the specified size, the status code 500 is returned. If you use the POST method and there is no message body, or if you use the GET method, the status code 200 is returned.</p> | None                 | <ul style="list-style-type: none"> <li>Optional<br/>GET<br/>method</li> <li>Required<br/>POST<br/>method</li> </ul> |
| Accept         | <p>The data format of the response message body. Always set this to application/json.</p> <p>if you use the POST method and you specify a value other than application/json, the status code 406 is returned.</p> <p>If you use the POST method and there is no message body, or if you use the GET method and you specify a value other than application/json, the status code 200 is returned.</p>                                                                                                                                                                                                                                                                                            | application/<br>json | Optional                                                                                                            |
| Cookie         | <p>If you issue REST API requests consecutively without logging in again, specify cookie information for login API responses.</p> <p>Specifying cookie enables the session to be maintained, eliminating the need to log in or out every time you issue a REST API request. The session is discarded automatically three minutes after the last REST API request is issued.</p> <p>If you do not want to maintain the session, you do not have to specify this header.</p> <p>In addition, do not specify it if you use authentication (Basic authentication) with login information added to a REST API.</p>                                                                                   | None                 | Optional                                                                                                            |

If you specify a property that is not listed in the table above, the property is ignored.

## 5.2.4 Limitation on the request body size

JP1/IM API limits the request body size to less than 10 MB. If the size exceeds 10 MB, the status code 413 is returned and the error message KAJY00009-E is issued. For details on the message, see the *JP1/Integrated Management 3 - Manager Messages*.

## 5.2.5 Response format

The following describes the format of a response:

```
httpVersion statusCode
responseHeader

messageBody
```

Table 5–6: Response format in detail

| Item                  | Description                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>httpVersion</i>    | As the version of the communication protocol used by an API, HTTP/1.1 is returned.                                                      |
| <i>statusCode</i>     | Returns a status code that indicates the result of the processed request.                                                               |
| <i>responseHeader</i> | Returns the data format of the response, which was specified in the request header.                                                     |
| <i>messageBody</i>    | Returns the message body data as follows: <ul style="list-style-type: none"><li>• Data format: JSON</li><li>• Encoding: UTF-8</li></ul> |

### (1) Status codes

The following table lists status codes to be returned when an API is run. Possible returned status codes are different for each API. For details, see the description of each API.

Table 5–7: Status codes

| Status code | Message                                       | Description                                                                                                                       |
|-------------|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 200         | For details, see the description of each API. | The request was processed successfully.                                                                                           |
| 400         | Bad-request                                   | The request is invalid.                                                                                                           |
| 401         | Unauthorized                                  | Could not be authenticated. Information for authentication or authorization is invalid.                                           |
| 403         | Forbidden                                     | There is no permission to run the request.                                                                                        |
| 404         | Not-found                                     | The requested resource is not found or no operation is found for the resource. Or a specified parameter is invalid.               |
| 406         | Not-acceptable                                | The specified response format is not supported.                                                                                   |
| 411         | Length Required                               | When the POST method is used, the Content-Length property of the request header is omitted.                                       |
| 413         | Payload Too Large                             | The size of the request body exceeds the upper limit.                                                                             |
| 415         | Unsupported media type                        | The specified request format is not supported.                                                                                    |
| 500         | Server-error                                  | An error occurred with the server processing.                                                                                     |
| 503         | Service Unavailable                           | The Intelligent Integrated Management Base service is unavailable. This might be caused by a temporal congestion or other reason. |

### (2) Response header

The following table describes response headers controlled by the Intelligent Integrated Management Base.

Table 5–8: Response header

| Header           | Description                                                                                                                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cache-Control    | Specify the following so that the API response is not cached.<br><br><pre>--- Cache-Control: no-store, no-cache, max-age=0 Pragma: no-cache Expires: Thu, 01 Jan 1970 00:00:00 GMT</pre>                                |
| Content-Type     | The data format of the response data. application/json is always returned as a fixed value.                                                                                                                             |
| WWW-Authenticate | Indicates that authentication is required when authentication with login information added to a REST API (Basic authentication) is used.<br><br><pre>--- WWW-Authenticate: Basic realm="JP1 Authentication Realm"</pre> |

## 5.2.6 Error response message

The following exception object is returned in the response message body if the status code is not 200:

```
{
  "timestamp":1539923958358,
  "status":403,
  "error":"Forbidden",
  "exception":"jp.co.hitachi_solutions.it_service_cooperation_framework.securi
ty.ImDdBadCredentialsException",
  "message":"Login processing failed due to an invalid parameter.,
  "path":"/im/api/v1/login",
  "messageId":"KAJY52001-E",
  "returnCode":3
}
```

Table 5–9: Error response format in detail

| Item       | Description                                                                                  |
|------------|----------------------------------------------------------------------------------------------|
| timestamp  | Specifies the elapsed time (in milliseconds) since 1970-01-01 00:00 in UTC.                  |
| status     | statusCode in response format                                                                |
| exception  | The class of the exception object                                                            |
| message    | The message stored in the exception object.<br>(A string obtained by Throwable#getMessage()) |
| path       | The path and subsequent string in the URI of the issued REST API                             |
| messageId  | The JP1 message ID                                                                           |
| returnCode | The return value of the REST API                                                             |
| extensions | Extended response information                                                                |

## 5.2.7 Data types

The following table describes data types supported by JP1/IM API.

Table 5–10: Supported data types

| Data type | Description                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------|
| boolean   | true or false                                                                                                  |
| int       | 32-bit signed integer                                                                                          |
| long      | 64-bit signed integer                                                                                          |
| string    | Text data<br>Unless otherwise specified, a number is handled as a decimal number if dealt with as string type. |

If you use a character listed in the following table as string type in JSON format, use the escape character for it.

Table 5–11: String type characters that need to be escaped in JSON format

| Character                 | Escaped character |
|---------------------------|-------------------|
| Double quotation mark (") | \ "               |
| Backslash (\)             | \\                |
| Backspace                 | \b                |
| Form feed                 | \f                |
| Line feed                 | \n                |
| Carriage return           | \r                |
| Tab                       | \t                |

Dates and times must be specified in the ISO8601 format, as described below. Return values also take the same format.

Format

```
YYYY-MM-DDThh:mm:ssTZD
```

Table 5–12: Format of the date and time

| Placeholder | Description                                                                                                      | Acceptable value                                                                                                         |
|-------------|------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| YYYY        | Specifies the year.                                                                                              | 1994 to 2099 (year)                                                                                                      |
| MM          | Specifies the month.                                                                                             | 01 to 12 (month of the year)                                                                                             |
| DD          | Specifies the day.                                                                                               | 01 to the last day of the specified month (day of the month)                                                             |
| hh          | Specifies the hour.                                                                                              | 00 to 23 (hour)                                                                                                          |
| mm          | Specifies the minute.                                                                                            | 00 to 59 (minute)                                                                                                        |
| ss          | Specifies the second.                                                                                            | 00 to 59 (second)                                                                                                        |
| TZD         | Specifies the time difference between the time zone of the specified value and Coordinated Universal Time (UTC). | <ul style="list-style-type: none"><li>For UTC<br/>Z</li><li>For time zones other than UTC<br/>+hh:mm or -hh:mm</li></ul> |

For example, 2019-03-01 12:00:00 in UTC is represented by 2019-03-01T21:00:00+09:00 in Japan Standard Time, or 2019-03-01T07:00:00-05:00 in US Eastern Standard Time.

In some countries and territories, the daylight saving time must be considered. For example, IM-DD specifies 2019-04-01T08:00:00-04:00 in US Eastern Standard Time (Daylight Saving Time) to represent 2019-04-01 12:00:00 in UTC.

## 5.2.8 Authentication methods for REST API

In order for users to issue API requests and get responses, they must be authenticated first. The following types of authentication are available on the Intelligent Integrated Management Base:

- Authentication by using the login API
- Authentication through login information added to a REST API (Basic authentication)
- Authentication through login information added to a REST API (OpenID authentication)
- Authentication through client secret information added to a REST API (Basic authentication)

### (1) Authentication by using the login API

The following describes steps for authentication with the login API.

#### 1. Invoke the login API.

Provide the JP1 user name and password to be authenticated and then, if successful, receive the token string and cookie string. For details on the login API, see [5.4.1 Login](#).

#### 2. Invoke a REST API.

To invoke a REST API, set the following HTTP request header with the token string that was retrieved by the login API.

You can invoke the REST APIs other than login and logout.

Request header

Authorization

Value to be specified

Bearer *token-string*

Example of a specification

For example, if the token string `anAxYWRtaW46TUdGa01tTTJNMlV3TURFNh6STNYekE0T2p` is obtained by the login API, specify as follows:

```
Authorization: Bearer anAxYWRtaW46TUdGa01tTTJNMlV3TURFNh6STNYekE0T2p
```

#### 3. Invoke the logout API.

Use the cookie string that was retrieved by the login API to discard the authentication information that is used for the current login. For details on the logout API, see [5.4.2 Logout](#).

### (2) Authentication through login information added to a REST API (Basic authentication)

The following shows the procedure for Basic authentication through login information added to a REST API.

By default, the Basic authentication setting is disabled. To enable it, set the `jp1.imdd.authBasic` property to `true` in the Intelligent Integrated Management Base definition file (`imdd.properties`).

For details on the Intelligent Integrated Management Base definition file (`imdd.properties`), see [Intelligent Integrated Management Base definition file \(imdd.properties\)](#) in *Chapter 2. Definition Files*.

#### 1. Invoke a given REST API.

In the HTTP request header on invocation of a REST API, specify `Basic` as the authentication method, followed by a Base64-encoded string of the user name concatenated with the password using `:` (ASCII: 0x3A) (which is called a *basic token*).

Request header

`Authorization`

Value to be specified

`"Basic " + Base64-encoded ASCII string of JP1-user-name:password`

Example of a specification

If the JP1 user is `jp1user` and the password is `password`, then use the Base64-encoded string of `jp1user:password`, `anAxdXNlcjpwYXNzd29yZA==`, to specify the basic token as shown below:

`Authorization: Basic anAxdXNlcjpwYXNzd29yZA==`

### Important

- Do not specify any cookie in the request header because Basic authentication is a stateless authentication method.
- Basic authentication can be used with either of HTTP or HTTPS, but we recommend access over HTTPS for better security.
- The authentication server performs authentication every time a REST API is executed, and therefore each authentication operation outputs a message related to the user management function to the server. If the authentication server also has a system that outputs integrated trace logs, design the system configuration with the possibility that the messages related to the user management function may cause a high load on the integrated trace in mind.

## (3) Authentication through login information added to a REST API (OpenID authentication)

The following shows a procedure for OpenID authentication by using login information added to a REST API.

OpenID authentication is disabled by default. To enable it, you have to edit the OpenID provider-related properties provided in the Intelligent Integrated Management Base definition file (`imdd.properties`).

For details on the Intelligent Integrated Management Base definition file (`imdd.properties`), see [Intelligent Integrated Management Base definition file \(imdd.properties\)](#) in *Chapter 2. Definition Files*.

#### 1. Invoke a REST API.

In the HTTP request header for invoking a REST API, specify `Bearer` as the authentication method, and then the access token submitted by the OpenID provider.

Request header

`Authorization`

## Value to be specified

`Bearer string-representing-access-token`

- When multiple OpenID providers are set as the authentication infrastructures on the Intelligent Integrated Management Base, you must specify the key name (access token issuer) of the OpenID provider in the HTTP request header `X-Token-Issuer` that is used to invoke a REST API. The key name that you specify here must be the one that is defined in the Intelligent Integrated Management Base definition file (`imdd.properties`).
- If, upon the acceptance of the processing of the REST API by the Intelligent Integrated Management Base, it turns out that the HTTP request header `X-Token-Issuer` is not specified or that the value specified for `X-Token-Issuer` does not match the OpenID provider's key name defined in the Intelligent Integrated Management Base definition file (`imdd.properties`), an authentication error occurs. In this case, the status code 403 and the error message `KAJY52030-E` are returned to the caller of the REST API.
- When only one OpenID provider is set as the authentication infrastructure on the Intelligent Integrated Management Base, you do not have to specify the HTTP request header `X-Token-Issuer` that is used to invoke a REST API. When this HTTP request header is not specified, the Intelligent Integrated Management Base processes the REST API assuming that the OpenID provider defined in the Intelligent Integrated Management Base definition file (`imdd.properties`) is the access token issuer.
- `X-Token-Issuer` is a unique request header defined in the Intelligent Integrated Management Base, which has the following format:

| Request header              | Value to be specified                                                                                                                                                                                                              |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X-Token-Issuer</code> | Name of the OpenID provider that issued the access token.<br>Specify the value representing the OpenID provider's key name defined in the Intelligent Integrated Management Base definition file ( <code>imdd.properties</code> ). |

### Example 1

- The access token is issued by Keycloak.
- Only one OpenID provider is set as the authentication infrastructure on the Intelligent Integrated Management Base definition file.

The key name of the OpenID provider (Keycloak)

- The access token submitted by the OpenID provider is `ABCDEFGH.IJKLMNOP.OPQRSTUVWXYZ`.

Under the conditions described above, set the access token in the request header as follows:

`Authorization: Bearer ABCDEFGH.IJKLMNOP.OPQRSTUVWXYZ`

### Example 2

- The access token is issued by Keycloak.
- Multiple OpenID providers (Keycloak and Okta) are set as the authentication infrastructures on the Intelligent Integrated Management Base.

The key name of one OpenID provider (Keycloak)

The key name of the other OpenID provider (Okta)

- The access token submitted by the OpenID provider is `ABCDEFGH.IJKLMNOP.OPQRSTUVWXYZ`.

Under the conditions described above, set the access token and the token issuer in the request headers as follows:

`Authorization: Bearer ABCDEFGH.IJKLMNOP.OPQRSTUVWXYZ`

`X-Token-Issuer: Keycloak`

## ! Important

- Although HTTP and HTTPS are both supported, we strongly recommend the use of HTTPS for OpenID authentication to protect against man-in-the-middle attacks. During operation, make sure to use HTTPS for access.
- In order to allow the JP1 user name used with the Intelligent Integrated Management Base to be mapped with the user name registered with the OpenID provider, the `preferred_username` claim of the access token must contain the name of the user logging in to the Open ID provider. When Keycloak is the issuer of the access token, the `preferred_username` claim is set in the access token by default. When Okta is the issuer of the access token, you must manually set the `preferred_username` claim. For details on how to set the `preferred_username` claim, see the document supplied by Okta. When the `preferred_username` claim is not set, the error message KAJY52028-E is returned. For details on the single sign-on mapping definition, see [Single sign-on mapping definition file \(`imdd\_sso\_mapping.properties`\)](#) in Chapter 2. Definition Files.

## (4) Authentication through client secret information added to a REST API (Basic authentication)

The following shows the flow of Basic authentication based on client secret data added to REST API. This authentication is also used for integrated agent to Integrated manager communication and is therefore enable at all times. In addition, REST API on which this authentication can be used is limited to API used by the system. For details, see 3.7 *Initial secret and IM client secret* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

Because this authentication does not use JP1 users, it does not handle Login and Log out. In addition, the privilege does not set the privilege to the client (subject to authentication), so access-restriction by the privilege is not performed.

The outcome of authentication is printed to the secret authentication logging file.

### 1. Call any REST API.

In HTTP request header at the time of REST API call, specify authentication method (you can specify `Basic` or `basic_auth`) followed by Base64 encoded string-called client token-that is the concatenation of user name and password with ":" (ASCII:0x3A).

Request header

Authorization

Value to be specified

- In case of specifying `Basic` as the authentication method:

"Basic " + Base64-encoded ASCII string of *client-ID:client-secret*

- In case of specifying `basic_auth` as the authentication method:

"basic\_auth " + Base64-encoded ASCII string of *client-ID:client-secret*

Example of a specification

If the client ID is `>client` and the client secret is `secret`, then use the Base64-encoded string of `>client:secret,PmNsaWVudDpzZWNYZXQ=`, to specify the basic token as shown below:

- In case of specifying `Basic` as the authentication method:

Authorization: Basic PmNsaWVudDpzZWNYZXQ=

- In case of specifying `basic_auth` as the authentication method:

Authorization: basic\_auth PmNsaWVudDpzZWNYZXQ=

### Important

- Do not specify any cookie in the request header because Basic authentication is a stateless authentication method.
- Basic authentication can be used with either of HTTP or HTTPS, but we recommend access over HTTPS for better security.

## 5.3 Explanation format for an API

---

The following lists sections to explain an API. Some sections are applicable only for some APIs, but not for others.

### **Description**

Describes what you can do with the API.

### **Execution permissions**

Lists permissions and roles required to run the API.

### **API version**

Indicates the API version.

### **Format**

Describes API request and response formats.

### **Parameters**

Describes parameters to be specified in the request message body.

### **Status codes**

Describes status codes that are returned as a response to the API that is run over the http or https protocol. For details on the status codes when an error occurs before an API is run, see [5.2.5\(1\) Status codes](#).

### **Return values**

Describes return values that are returned by the API.

### **Examples**

Describes request and response examples to use the API.

Note that examples in this chapter use the http protocol. If you want to use the https protocol, you need to replace HTTP with HTTPS.

# 5.4 API for user authentication

This section describes operations related to the API for user authentication.

## 5.4.1 Login

### Description

Logs in to the Intelligent Integrated Management Base according to the specified request.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/login/ httpVersion
```

Request message body

```
{
  "user": user-name,
  "password": password
}
```

Response message body

```
{
  "jpluser": JP1-user,
  "jpltoken": JP1-authentication-token,
  "token": Authorization-header-authentication-token,
  "clientId": client-ID,
  "permissions": [
    JP1-user-permissions, ...
  ]
}
```

### Parameters

user

Specify the user name as a string value.

password

Specify the password as a string value.

### Status codes

The following table describes the status codes that are returned as a response to the request.

| Status code | Message | Description          |
|-------------|---------|----------------------|
| 200         | --      | The login succeeded. |

| Status code | Message     | Description                                                            |
|-------------|-------------|------------------------------------------------------------------------|
| 403         | KAJY52001-E | The login failed due to an invalid parameter.                          |
|             | KAJY52002-E | Could not communicate with the server that stores authentication data. |
|             | KAJY52003-E | The login failed due to an internal error.                             |
|             | KAJY52004-E | There is no permission to log in.                                      |

For details on the messages, see the *JP1/Integrated Management 3 - Manager Messages*.

## Return values

The following information is returned in the response header:

| Parameter name | Description   |
|----------------|---------------|
| Set-Cookie     | Cookie string |

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                           |
|-----|-------------|-----------|-------------------------------------------------------|
| 1   | jpluser     | string    | The JP1 user name                                     |
| 2   | jpltoken    | string    | The JP1 authentication token                          |
| 3   | token       | string    | The authentication token for the Authorization header |
| 4   | clientId    | string    | The identifier to identify the client uniquely        |
| 5   | permissions | array     | An array of JP1 permission strings                    |

The following exception object is returned in the response message body if the status code is not 200:

| No. | Member name | Data type | Description          |
|-----|-------------|-----------|----------------------|
| 1   | returnCode  | string    | Detailed reason code |

## Examples

### Example of invoking the login API

```
POST http://hostname:xxxxx/im/api/v1/login HTTP/1.1

{
  "user": "jpladmin",
  "password": "password"
}
```

### Example of a response to the login API

```
HTTP/1.1 200 OK
Set-Cookie: JSESSIONID=7F2FB43CF4829025661D9E139E911B3B

{
  "jpluser": "jpladmin",
  "jpltoken": "MGFkMmM2M2UwMDE4XzI3XzA4OjI0OjMzX19fX19fX19fX19fX2
pwMWFkbWluICAgICAgICAgICAgICAgICAgICAgICAg",
  "token": "anAxyWRtaW46TUdGa01tTTJNM1V3TURFNh6STNYekE0T2pJME9qTXpYM
TlmWDE5ZlgxOWZYMtMwDE5ZlgycHdNV0ZrYlJsdU1DQWdJQ0FnSUNBZ01DQWdJQ0FnSUNB
Z01DQWdJQ0Fn",
  "clientId": "02157e39-2248-4a0e-8b63-78ffb4296e28",
  "permissions": {
```

```
    "": [/*omitted*/]  
  }  
}
```

## 5.4.2 Logout

### Description

Discards the authentication information that is used for the current login.

### Execution permissions

None.

### API version

v1

### Format

#### Request line

```
POST /application/component/apiVersion/logout/ httpVersion
```

#### Request header

```
Cookie: cookie-information
```

#### Request message body

None.

#### Response header

```
Set-Cookie: cookie-information
```

#### Response message body

```
true
```

### Parameters

Cookie

Specify the cookie string.

### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message | Description           |
|-------------|---------|-----------------------|
| 200         | --      | The logout succeeded. |

### Return values

The following information is returned in the response header:

| Parameter name | Description   |
|----------------|---------------|
| Set-Cookie     | Cookie string |

## Examples

### Example of invoking the logout API

```
POST http://hostname:xxxxx/im/api/v1/logout HTTP/1.1
Cookie: JSESSIONID=7F2FB43CF4829025661D9E139E911B3B
```

## 5.4.3 Initial secret issue

### Description

Issue initial secret.

To work with the manager, you must allocate client secret for each client that you want to authentication. Working with managers until they get client secret is one that is assigned to the manager and can temporarily use initial secret that is shared by all requestors.

The secret you publish is stored in integrated agent host administration DB.

### Execution permissions

Following permissions are required:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/secret/generateInfo httpVersion
```

Request message body

None

Response message body

```
{
  "secret": secret-for-authentication,
  "lastUpdateTime": generation-date/time-of-secret
}
```

### Parameter

None

### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                  |
|-------------|-------------|--------------------------------------------------------------|
| 200         | --          | API operation was successful.                                |
| 403         | KAJY01000-E | Insufficient privilege for the user used for authentication. |
| 500         | KAJY68001-E | DB accessible error                                          |

### Return values

The following information is returned in the response body if the status code is 200:

| Member name    | Data type | Description                                                                                                     |
|----------------|-----------|-----------------------------------------------------------------------------------------------------------------|
| secret         | string    | Issued secret                                                                                                   |
| lastUpdateTime | string    | Secret publishing date/time<br>The format is UTC time of day "YYYY-MM-DDThh:mm:ssZ" in ISO8601 extended format. |

### Error message output

API response, including the content of the error message, is returned to the caller when an Execute of Error occurs.  
The caller displays Message at the caller, using the information of the received response.

### Examples

The example below executes the API:

Request:

```
POST http://immhost01:20703/im/api/v1/secret/generateInfo
```

Manager host name: immhost01

Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json

{
  "secret": "Issued-secret",
  "lastUpdateTime": "2022-10-20T12:25:45Z"
}
```

## 5.4.4 IM Client secret delete

### Description

Delete IM client secret that was added to the database.

### Execution permissions

Following permissions are required:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/secret/client/deleteInfo httpVersion
```

Request message body

```
{
  "clientIds": [ IM-client-ID, .... ]
}
```

Here are the parameters that you specify for message body of the request:

| Member name | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|-----------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clientIds   | string[]  | No       | <p>Specifies the listing of ID of IM client secret that you want to delete.</p> <p>When working with JP1/IM, the elements of a listing can be any text.</p> <p>However, the following character strings cannot be specified:</p> <ul style="list-style-type: none"><li>• String beginning with "AGENT_"</li><li>• Strings beginning with "MANAGER_" other than "MANAGER__INTEGRATED_host name"</li></ul> <p>The number of characters that can be specified is 1~280, and the characters that can be specified are ASCII codes (0x20~0x7e (excluding ":")).</p> |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                    |
|-------------|-------------|--------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                                                                  |
| 400         | KAJY68002-E | The request parameter is invalid.                                                                                              |
| 403         | KAJY01000-E | Insufficient privilege for the user used for authentication.                                                                   |
| 500         | KAJY68007-E | <ul style="list-style-type: none"><li>• DB accessible error</li><li>• The specified IM client ID is not added on DB.</li></ul> |

## Error message output

API response, including the content of the error message, is returned to the caller when an Execute of Error occurs.  
The caller displays Message at the caller, using the information of the received response.

## Examples

The example below executes the API:

Request:

```
POST http://immhost01:20703/im/api/v1/secret/client/deleteInfo

{
  "clientIds": [ "clientId1", "clientId2" ]
}
```

Manager host name: immhost01

Response:

```
< HTTP/1.1 500 Internal Server Error
< Content-Type: application/json
{
  "timestamp": 1585561108345,
  "status": 500,
  "error": "Internal Server Error",
  "exception": "XXXXXXXXXXXXXXXXXXXXXXX",
  "message": "Failed to delete an IM client secret.",
  "path": "/im/api/v1/secret/client/deleteInfo ",
  "messageId": " KAJY68007-E"
}
```

## 5.4.5 IM Client secret issue

### Description

Issue IM client secret.

When linking a manager host with a user-specific OSS, or a CloudWatch Logs/AzureMonitor provided by JP1/IM - Manager or lower manager, use IM client secret to perform authentication by communicating with the intelligent integrated management infrastructure and the partner.

### Execution permissions

Following permissions are required:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/secret/client/generateInfo httpVersion
```

Request message body

```
{
  "clientId": IM-client-ID
}
```

Response message body

```
{
  "clientSecret": IM-client-secret-for-authentication,
  "lastUpdateTime": IM-client-secret-issue-date/time
}
```

Here are the parameters that you specify for message body of the request:

| Member name | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clientId    | string    | No       | Specifies the listing of ID of IM client secret that you want to issue.<br>When working with JP1/IM, the elements of a listing can be any text.<br>However, the following character strings cannot be specified: <ul style="list-style-type: none"><li>• String beginning with "AGENT_"</li><li>• String beginning with "MANAGER_"</li></ul> The number of characters that can be specified is 1~280, and the characters that can be specified are ASCII codes (0x20~0x7e (excluding ":")). |

### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                           |
|-------------|-------------|---------------------------------------|
| 200         | --          | API operation was successful.         |
| 400         | KAJY68002-E | The request parameter is invalid.     |
| 400         | KAJY68004-E | The same IM client ID has been added. |

| Status code | Message     | Description                                                  |
|-------------|-------------|--------------------------------------------------------------|
| 403         | KAJY01000-E | Insufficient privilege for the user used for authentication. |
| 500         | KAJY68008-E | DB accessible error                                          |

### Return values

The following information is returned in the response body if the status code is 200:

| Member name    | Data type | Description                                                                                                               |
|----------------|-----------|---------------------------------------------------------------------------------------------------------------------------|
| clientSecret   | string    | Issued IM client secret                                                                                                   |
| lastUpdateTime | string    | IM client secret publishing date/time<br>The format is UTC time of day "YYYY-MM-DDThh:mm:ssZ" in ISO8601 extended format. |

### Error message output

API response, including the content of the error message, is returned to the caller when an Execute of Error occurs. The caller displays Message at the caller, using the information of the received response.

### Examples

The example below executes the API:

Request:

```
POST http://immhost01:20703/im/api/v1/secret/client/generateInfo
{
  "clientId": "clientSecret1"
}
```

Manager host name: immhost01

Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json
{
  "clientSecret": "Issued-IM-client-secret",
  "lastUpdateTime": "2022-10-20T12:25:45Z"
}
```

## 5.4.6 IM Client list acquisition

### Description

Retrieves a list of IM client ID that have been added.

When linking the manager host with your own OSS, or CloudWatch Logs/AzureMonitor provided by JP1/IM - Manager or lower manager, use IM client secret to authentication communication between Intelligent Integrated Management Base and the partner.

### Execution permissions

Following permissions are required:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

## API version

v1

## Format

### Request line

```
GET /application/component/apiVersion/secret/client/list httpVersion
```

### Request message body

None

### Response message body

```
{
  "clientIds": [IM-client-ID,...]
}
```

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                  |
|-------------|-------------|--------------------------------------------------------------|
| 200         | --          | API operation was successful.                                |
| 403         | KAJY01000-E | Insufficient privilege for the user used for authentication. |
| 500         | KAJY68009-E | DB accessible error                                          |

## Return values

The following information is returned in the response body if the status code is 200:

| Member name | Data type | Description                              |
|-------------|-----------|------------------------------------------|
| clientIds   | string[]  | Array of ID identifying IM client secret |

## Error message output

API response, including the content of the error message, is returned to the caller when an Execute of Error occurs. The caller displays Message at the caller, using the information of the received response.

## Examples

The example below executes the API:

### Request:

```
GET http://immhost01:20703/im/api/v1/secret/client/list
```

Manager host name: immhost01

### Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json
{
  "clientIds": [ "clientid1", "clientid2" ]
}
```

## 5.5 API for link information

---

This section describes operations related to API of link information.

### 5.5.1 Link information acquisition

#### Description

Gets the link information that represents order relationships between objects, such as jobs.

When link information is registered in the system, the link information that satisfies the specified criteria, such as before or after a particular object, is retrieved.

#### Execution permissions

See *Appendix E.1 Operating permissions required for system monitoring using the Intelligent Integrated Management Base* in the *JPI/Integrated Management 3 - Manager Overview and System Design Guide*.

#### API version

v1

#### Format

Request line

```
POST /application/component/apiVersion/links httpVersion
```

Request message body

```
{
  "type": type-of-the-target,
  "sid": target-IM-management-node-SID,
  "fromLayerCount": layer-count-of-the-preceding-node,
  "toLayerCount": layer-count-of-the-succeeding-node,
  "countPerLayer": node-count-per-layer,
  "linkCount": node-relationship-count
}
```

Response message body

```
{
  "links": [
    {
      "from": the-preceding-node-SID,
      "to": the-succeeding-node-SID,
      "type": type-of-the-target
    }, ...
  ],
  "exceedCountDetected": {
    "countPerLayer": {
      ...,
      "layer-2": whether-node-count-for-layer-2-exceeds-the-upper-limit,
      "layer-1": whether-node-count-for-layer-1-exceeds-the-upper-limit,
      "layer0": whether-node-count-for-layer0-exceeds-the-upper-limit,
      "layer1": whether-node-count-for-layer1-exceeds-the-upper-limit
    }
  }
}
```

```

        "layer2": whether-node-count-for-layer2-exceeds-the-upper-limit,
        ...
    },
    "linkCount": whether-node-relationship-count-exceeds-the-upper-limit
},
"messageId": message-ID,
"message": message
}

```

## Parameters

### type

Specify the type of the link information that you want to retrieve, among the link information types applied to the system.

type describes a grouping of relations that have the same meaning. On the **Related node** tab in the Integrated Operation Viewer window, you can filter relations to display only those belonging to a specific type.

For relations within a JP1/IM product or between a JP1/IM product and another product, the following types are used. In addition to these types, the use of user-specified types is also allowed.

- rootJobnetExecutionOrder: Relation of the execution order of root jobnets
- managerAgent: Relation between the manager and agent of a JP1 product
- rootJobnetAgent: Relation between a root jobnet and an AJS agent
- sameNode: Relation between nodes with the same name
- L2Connection: Relation between layer-2 connection lines managed by JP1/NNMi
- Infrastructure: Relation between infrastructure resources managed by JP1/OA
- monitoringConfiguration: Relation between a product and a monitoring target in a monitoring product configuration

If this attribute is omitted or it is set to an empty string, the applicable link information is returned regardless of the type of the information.

If this attribute is specified, the link information for the specified type among applicable sets of link information is returned.

### sid

Specify the SID of the target node. The information on the preceding and succeeding nodes of the specified target is returned.

(Example) When specifying a root jobnet:

```

_JP1AJS-M_JP1/AJS3-manager-host-name/_HOST_JP1/AJS3-manager-host-name/
_JP1SCHE_scheduler-service-name/_JP1JOBG_job-group-name_JP1ROOTJOBNET_node-name

```

Omitting this parameter causes all link information to be retrieved.

### fromLayerCount

Specify the maximum number of layers of the preceding node to be retrieved, in the range of 0 to 2147483647.

If sid is specified, the fromLayerCount parameter cannot be omitted.

If sid is omitted, the value specified for the fromLayerCount parameter is ignored.

If the same node exists in more than one layer in link information, the number of layers can exceed the specified value depending on how layers are interpreted.

If this can cause a problem, check whether the excess occurs while retrieving link information before using it.

toLayerCount

Specify the maximum number of layers of the succeeding node to be retrieved, in the range of 0 to 2147483647.

If `sid` is specified, the `toLayerCount` parameter cannot be omitted.

If `sid` is omitted, the value specified for the `toLayerCount` parameter is ignored.

If the same node exists in more than one layer in link information, the number of layers can exceed the specified value depending on how layers are interpreted.

If this can cause a problem, check whether the excess occurs while retrieving link information before using it.

countPerLayer

Specify the maximum number of nodes to be retrieved for each node layer, in the range of 1 to 2147483647.

If `sid` is specified, the `countPerLayer` parameter cannot be omitted.

If `sid` is omitted, the value specified for the `countPerLayer` parameter is ignored.

If the same node exists in more than one layer in link information, the number of layers can exceed the specified value depending on how layers are interpreted.

If this can cause a problem, check whether the excess occurs while retrieving link information before using it.

linkCount

Specify the maximum number of node-node relationships (the number of pairs of preceding and succeeding nodes) to be retrieved, in the range of 1 to 2147483647.

If `sid` is specified, the `linkCount` parameter cannot be omitted.

If `sid` is omitted, the value specified for the `linkCount` parameter is ignored.

If the same node exists in more than one layer in link information, the number of layers can exceed the specified value depending on how layers are interpreted.

If this can cause a problem, check whether the excess occurs while retrieving link information before using it.

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                               |
|-------------|-------------|---------------------------------------------------------------------------------------------------------------------------|
| 200         | None        | There is no data that has not been returned because of the upper limit restriction.                                       |
|             | KAJY22000-W | There is data that has not been returned because of the upper limit restriction.                                          |
| 400         | KAJY22002-E | The request has a parameter with an invalid format. (The key does not exist or specification and data type are different) |
| 500         | KAJY22002-E | The request has a parameter with an invalid format. (The value is invalid.)                                               |

For details on the messages, see the *JPI/Integrated Management 3 - Manager Messages*.

## Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                                                                     |
|-----|-------------|-----------|-------------------------------------------------------------------------------------------------|
| 1   | links       | array     | An array of response objects.<br>The order of the array is irrelevant.                          |
| 2   | from        | string    | The preceding node.<br>The format is the same as that of <code>sid</code> in the message body.  |
| 3   | to          | string    | The succeeding node.<br>The format is the same as that of <code>sid</code> in the message body. |

| No. | Member name         | Data type | Description                                                                                                                                                                                                                                                                                                                                                      |
|-----|---------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | type                | string    | The same value as type of the request parameter.                                                                                                                                                                                                                                                                                                                 |
| 5   | exceedCountDetected | object    | Whether the specified upper limit for a parameter is exceeded.<br>Each parameter has members. If sid is not specified, none is returned.                                                                                                                                                                                                                         |
| 6   | countPerLayer       | boolean   | Whether the number of nodes per layer exceeds the upper limit.<br>Each layer has members.                                                                                                                                                                                                                                                                        |
| 7   | layerinteger        | string    | Whether the number of nodes per layer exceeds the upper limit (for all the target layers).<br>A number is assigned to integer as follows:<br>0 for the layer specified as sid, +1 for the succeeding layer, and -1 for the preceding layer. The number is incremented by one for further succeeding layers, and decremented by one for further preceding layers. |
| 8   | linkCount           | boolean   | Whether the number of links exceeds the upper limit.<br><ul style="list-style-type: none"> <li>• true: Exceeded</li> <li>• false: Not exceeded</li> </ul>                                                                                                                                                                                                        |
| 9   | messageId           | string    | The message ID.<br>This is returned only if there is a message to be notified.                                                                                                                                                                                                                                                                                   |
| 10  | message             | string    | The message body.<br>The used language is determined by the value specified for the Accept-Language property in the HTTP request header.<br>This is returned only if there is a message to be notified.                                                                                                                                                          |

### Example 1

The example below executes the API in the following scenario:

- Identifiers for the target system
  - JP1/AJS3 manager host name: host1
  - Scheduler service name: scheduler1
  - Job group name: jobgroup1
  - Node name: rootjobnet3
- The number of layers of the preceding node to be retrieved: 100
- The number of layers of the succeeding node to be retrieved: 1
- The number of nodes to be retrieved per node layer: 100
- The number of node relationships to be retrieved: 100
- The relationship between nodes:

- Language used in messages: English

#### Request:

```
POST /im/api/v1/links 1.1
Authorization: Bearer XXXX
Accept-Language: ja
Content-Type: application/json
Accept: application/json
{
  "type": "rootJobnetExecutionOrder",
  "sid": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_scheduler1/_JP1JOBG_jo
bgroup1/_JP1ROOTJOBNET_rootjobnet3",
  "fromLayerCount": 100,
  "toLayerCount": 1,
  "countPerLayer": 100,
  "linkCount": 100
}
```

#### Response:

```
HTTP/1.1 200 OK
Content-Type: application/json
{
  "links": [
    {
      "from": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_scheduler2/_JP1JO
BG_jobgroup3._JP1ROOTJOBNET_rootjobnet1",
      "to": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_scheduler1/_JP1JOBG
_jobgroup1/_JP1ROOTJOBNET_rootjobnet3",
      "type": "rootJobnetExecutionOrder"
    },
    {
      "from": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_scheduler4/_JP1JO
BG_jobgroup3/_JP1ROOTJOBNET_rootjobnet2",
      "to": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_scheduler1/_JP1JOBG
_jobgroup1/_JP1ROOTJOBNET_rootjobnet3",
      "type": "rootJobnetExecutionOrder"
    },
    {
      "from": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_scheduler1/_JP1JO
BG_jobgroup1/_JP1ROOTJOBNET_rootjobnet3",
      "to": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_scheduler1/_JP1JOBG
_jobgroup2/_JP1ROOTJOBNET_rootjobnet4",
      "type": "rootJobnetExecutionOrder"
    }
  ],
  "exceedCountDetected": {
    "countPerLayer": {
      "layer-1": false,
      "layer0": false,
      "layer1": false,
    },
    "linkCount": false
  },
  "messageId": "KAJY22000-W",
  "message": "There is data that is not displayed because the upper 1
```

```
limit is reached. (item = succeeding node layer count)"
}
```

## 5.5.2 Link type list acquisition

### Description

Gets the list of types of link information applied to the system.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API version

v1

### Format

Request line

```
GET /im/api/v1/links/types httpVersion
```

Response message body

```
{
  "linkTypes": [
    {
      "name": "type-of-link-information"
    }
  ]
}
```

### Parameters

None

### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                    |
|-------------|-------------|----------------------------------------------------------------|
| 200         | None        | The list of link information types was retrieved successfully. |
| 403         | KAJY01000-E | There is no permission to run the REST API.                    |

### Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                   |
|-----|-------------|-----------|-------------------------------|
| 1   | linkTypes   | Object[]  | An array of link type objects |
| 2   | name        | string    | The SID of the preceding node |

## Example

### Request:

```
GET /im/api/v1/links/types HTTP/1.1
Authorization:Bearer xxxx
```

### Response:

```
HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json

{
  "linkTypes": [
    {
      "name": "rootJobnetExecutionOrder"
    },
    {
      "name": "sameNode"
    },
    ...
  ]
}
```

## 5.6 API for event management

---

This section describes operations for API of event management.

### 5.6.1 Event search

#### Description

Get events which related events to IM management node from the integrated monitoring database.

Specifying an IM management node as a parameter returns a list of events that were issued from the node.

Specifying search conditions as a parameter returns a list of events that match the conditions.

Events cannot be retrieved if the logged-in JP1 user has no permission to view the events. Note that such a case causes no error.

What kind of events you can get depends on the JP1 resource group settings and the event receiver filter settings in JP1/IM - Manager.

#### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

#### API version

v1

#### Format

Request line

```
POST /application/component/apiVersion/nodes/treeInfo/event httpVersion
```

Request message body

```
{
  "sid": "tree-SID-of-the-IM-management-node",
  "filter": "event-search-condition",
  "direction": "direction-of-the-event-search",
  "since": "start-position-of-the-event-search",
  "count": "number-of-events-to-be-obtained",
  "attrs": "list-of-event-attributes-to-be-obtained",
  "statusFilter": "statusFilter",
  "consolidateEvent": "whether-to-return-consolidated-repeated-events",
  "searchCount": "number-of-event-searches"
}
```

Response message body

```
{
  "eventData": [
    event-information-object, ...
  ],
  "messageId": "message-ID",
  "message": "message",
  "beginSid": "next-event-SID-at-the-start-position-of-the-JP1-event-sea"
```

```
rch",
  "endSid": "event-SID-at-the-end-position-of-the-JP1-event-search"
}
```

## Parameters

`sid`

Specify the tree SID of the IM management node as string type.

Obtains the list of events that occurred from the specified IM management nodes. If the parameter is omitted, it is assumed that all systems (`_ROOT_AllSystems`) is specified. Returns an empty list of events if you omit this parameter when the IM management nodes have not been set up.

`filter`

Specify the event search condition object, which stores arrays of conditions.

The system searches the integrated monitoring database for events based on the specified event search conditions. For details on the event search object, see [7.2.1\(3\) Event search condition object](#).

Narrow down the events of that are the target of the `sid` parameter using the event search conditions specified the `filter` parameter.

`direction`

Specify in which direction the event search proceeds.

- Into the past: `past`
- Into the future: `future`

Omitting this parameter causes `past` to be used.

`since`

Specify the SID of the JP1 event that serves as a starting point for the event search. The API searches for events that occurred either before or after the JP1 event corresponding to the specified SID. Note that the JP1 event corresponding to the specified SID is not included in the search.

If this parameter is omitted, the search will be started from the beginning or end of the integrated monitoring database according to the `direction` parameter.

For details on the JP1 event SID, see [7.2.1\(1\) Event information object](#).

`count`

Specify the maximum number of events to be retrieved in the range of 1 to 2000. Omitting this parameter causes the maximum number to be set to 2000.

`attrs`

Specify an array of event attributes that you want to get. The attributes specified in this parameter are retrieved in user-specified order.

Example

```
"attrs": ["B.ID", "B.MESSAGE", ...]
```

If this parameter is omitted, all the attributes that can be output by the output of event report functionality and the attributes listed in the table of *Event attributes of the consolidation start event* in [7.2.1\(1\) Event information object](#) are retrieved.

For details of the event report functionality, see [4.15.2 Saving event information in the integrated monitoring database \(CSV report\)](#) in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

`statusFilter`

When I perform narrowing of the status of the IM management node only by an applicable event, I appoint a value of the status with sequence of `int`.

For details of status of IM management node, see [5.8.5 IM management node status acquisition](#).

Example: If you want to obtain the events of which the statuses are 30 or 40.

```
"statusFilter": [30, 40]
```

#### consolidateEvent

Specify whether to return consolidated repeated events when repeated events are consolidated. Omitting this parameter causes the parameter to be set to `false`. If you do not want repeated events to be returned, specify `true`.

- `true`: If repeated-event display is suppressed with the Intelligent Integrated Management Base, only consolidation start events are returned. Repeated events after the consolidation start event are not returned.
- `false`: Repeated events are returned regardless of whether repeated-event display is suppressed with the Intelligent Integrated Management Base.

#### searchCount

Specify the upper limit for the number of event searches from 0 to 120,000.

Up to 100 events mapped with the IM management node specified by the `sid` parameter are searched for, starting from the search start position specified by the `since` parameter in the search direction of the `direction` parameter. If the number of events specified by the `count` parameter cannot be retrieved due to a reason such as an event receiver filter, the next 100 events are repeatedly searched for as the target. Specify the upper limit for the number of these repeated event searches.

If the number of searches reaches the upper limit, the search operation is suspended and the list of events retrieved successfully before the search ends is returned. If the parameter is omitted or if the value is set to 0, there will be no upper limit for the number of searches.

### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message                                         | Description                                                                                                                           |
|-------------|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| 200         | None                                            | A list of events was retrieved successfully.                                                                                          |
|             | KAJY32005-W                                     | A temporary error occurred during the event search.                                                                                   |
|             | KAJY32010-W                                     | Event retrieval was suspended because the event search to obtain events reaches the specified upper limit for the number of searches. |
| 400         | KAJY32200-E                                     | The request has a parameter with an invalid format.                                                                                   |
|             | KAJY32201-E                                     | The event search conditions (the <code>filter</code> parameter) are invalid.                                                          |
| 404         | KAJY32202-E                                     | The specified node does not exist on the manager.                                                                                     |
| 500         | KAJY32000-E<br>to<br>KAJY32004-E<br>KAJY32006-E | An error occurred during the event search process.                                                                                    |

For details on the messages, see the *JP1/Integrated Management 3 - Manager Messages*.

### Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                                                                                                                                                                                                                                                 |
|-----|-------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | eventData   | Object[]  | Returns an array of the event information objects that represents a list of retrieved events. For details on the event information object, see <a href="#">7.2.1(1) Event information object</a> .<br>If there is no event to be returned, a zero-length array is returned. |

| No. | Member name | Data type | Description                                                                                                                                                                                                                             |
|-----|-------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | messageId   | string    | Returns the message ID of the temporary error message that is generated during an event search. If there is no message to be notified, this information is not returned.                                                                |
| 3   | message     | string    | Returns the body of the temporary error message that is generated during an event search. If there is no message to be notified, this information is not returned.                                                                      |
| 4   | beginSid    | string    | Returns the next JP1 event SID at the start position of the event search. It is the next JP1 event SID in the direction of event retrieval starting from <code>since</code> .<br>It is omitted if there is no event to be searched for. |
| 5   | endSid      | string    | Returns the JP1 event SID at the end position of the event search. If event search is suspended, the JP1 event SID at the suspended position is returned.<br>It is omitted if there is no event to be searched for.                     |

### Example 1

The following example uses this API to get a list of events that are related to a JP1/AJS job group.

```
POST /im/api/v1/nodes/treeInfo/event HTTP/1.1
Authorization:Bearer xxxx
Accept-Language: ja
Content-Type: application/json
Accept: application/json

{
  "sid": " _ROOT_AllSystems/_SYSTEM_System1/_SYSTEM_SubSystem1/_HOST_host
1/_CATEGORY_Job/_SUBCATEGORY_JP1%2FAJS%20-%20Manager/_OBJECT_ScheduleServ
/_OBJECT_jobgroup",
  "count": "200",
  "attrs": [ "B.ID", "E.@JP1IM_DEALT", "E.SEVERITY" ]
}
```

### Example 2

The following example uses this API to get a list of events by specifying event search conditions.

Request:

```
POST /im/api/v1/nodes/treeInfo/event HTTP/1.1
Authorization:Bearer xxxx
Accept-Language: ja
Content-Type: application/json
Accept: application/json

{
  "filter": {
    "include": [
      [
        {"key": "E.SEVERITY", "ope": "IN", "val": ["Error", "Warning"]}
      ],
      [
        {"key": "B.SOURCESERVER", "ope": "IN", "val": ["host1", "host2",
"host3"]}
      ],
      [
        {"key": "E.SEVERITY", "ope": "IN", "val": ["Error", "Warning", "N
otice"]}
      ]
    ]
  }
}
```

```

        {"key": "B.SOURCESERVER", "ope": "IN", "val": ["host4", "host5"]}
      ],
      "exclude": [
        [
          {"key": " E.@JP1IM_DEALT", "ope": "IN", "val": "1"}
        ]
      ]
    }
  }
}

```

#### Response:

```

HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json

{
  "eventData": [
    {
      "sid": "_JP1IM_imhost1/_JP1IMSEQNO_697/_JP1IMEVBSEQNO_746",
      "value": [
        "B.ID": "00004107",
        "E.@JP1IM_DEALT": "0",
        "E.SEVERITY": "Error"
      ],
    },
    {
      "sid": "_JP1IM_imhost1/_JP1IMSEQNO_698/_JP1IMEVBSEQNO_747",
      "value": [
        "B.ID": "00004104",
        "E.@JP1IM_DEALT": "0",
        "E.SEVERITY": "Error"
      ],
    }
  ]
}

```

## 5.6.2 Event detailed information acquisition

### Description

Gets the details of a specified event.

The details of an event cannot be retrieved if the logged-in JP1 user has no permission to view the event.

The retrieved details of an event can include the attributes of the event, the event guide information, and the display names of the event attributes.

Event attributes and their display names to be included in the retrieved details of an event depend on the JP1/IM - Manager definition file for extended event attributes.

If the event guide information is set on JP1/IM - Manager, the event guide message for the retrieved event is included.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator

- JP1\_Console\_User

## API version

v1

## Format

### Request line

```
GET /application/component/apiVersion/events/detail?query httpVersion
```

### Response message body

```
{
  "eventData": event-information-object
}
```

## Parameters

sid

Specify the SID of a JP1 event for which you want to get details. For details on the SID of a JP1 event, see [7.2.1\(1\) Event information object](#).

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message                                                              | Description                                         |
|-------------|----------------------------------------------------------------------|-----------------------------------------------------|
| 200         | None                                                                 | The details were retrieved successfully.            |
| 400         | KAJY32210-E                                                          | The request has a parameter with an invalid format. |
| 404         | KAJY32211-E                                                          | The specified event could not be found.             |

For details on the messages, see the *JP1/Integrated Management 3 - Manager Messages*.

## Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                                                                                |
|-----|-------------|-----------|------------------------------------------------------------------------------------------------------------|
| 1   | eventData   | object    | Returns the event information object. For details, see <a href="#">7.2.1(1) Event information object</a> . |

## Example 1

The following example uses this API to get the details of a specified event.

### Request:

```
GET /im/api/v1/events/detail?sid=_JP1IM_imhost1/_JP1IMSEQNO_697/_JP1IME
VBSEQNO_746 HTTP/1.1
Authorization:Bearer xxxx
Accept-Language: ja
Content-Type: application/json
Accept: application/json
```

## Response:

```
HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json
{
  "eventData": {
    "sid": "_JP1IM_imhost1/_JP1IMSEQNO_697/_JP1IMEVBSEQNO_746",
    "value": [
      "B.ID":"00001F20",
      "B.MESSAGE":"An error occurred.",
      "E.STARTTIME":"2018-11-14T17:00:00Z",
      "E.@JP1IM_GUIDE":" Check the host1 host for an error.",
      ...
    ],
    "title": [
      "B.ID":"Event ID",
      "B.MESSAGE":"Message",
      "E.STARTTIME":"Start time",
      "E.@JP1IM_GUIDE":"Guide",
      ...
    ],
    "type": [
      "B.MESSAGE":"text",
      "E.STARTTIME":"date",
      "E.@JP1IM_GUIDE":"html",
      ...
    ]
  ]
}
```

## 5.6.3 Event status change

### Description

Changes the event status of the specified events.

An error is issued if the logged-in JP1 user has no permission to view the specified events.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/events/status httpVersion
```

Request message body

```
{
  "dealt":"event-status"
```

```

    "sid": [
        "JP1-event-SID", ...
    ]
}

```

#### Response message body

```

{
    "eventData": [
        event information object, ...
    ],
    "messageId": messageID,
    "message": message
}

```

### Parameters

dealt

Specify one of the following values for a state to which you want to change the event status:

- 0: Unprocessed
- 1: Processed
- 2: Processing
- 3: Held

sid

Specify an array containing the SIDs of events whose status you want to get. For details on the event SID, see [7.2.1\(1\) Event information object](#). You can specify up to 2,000 event SIDs.

### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message                          | Description                                                             |
|-------------|----------------------------------|-------------------------------------------------------------------------|
| 200         | None                             | The event status was changed successfully.                              |
|             | KAJY32110-W                      | Some events were not able to be handled due to insufficient permission. |
| 400         | KAJY32220-E                      | The request has a parameter with an invalid format.                     |
| 500         | KAJY32100-E<br>to<br>KAJY32109-E | An error occurred while the event status was being changed.             |
|             | KAJY32221-E                      | Cannot be executed due to a change to the event status.                 |

For details on the messages, see the *JP1/Integrated Management 3 - Manager Messages*.

### Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                                                                                                                                                                                                                                                                                                  |
|-----|-------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | eventData   | Object[]  | Returns the list of events of which statuses were modified as the array of event information objects. For details, see <a href="#">7.2.1(1) Event information object</a> .<br>Returns the event for which the operation was correctly performed if some of the events could not be operated due to an inadequate permission. |
| 2   | messageId   | string    | Returns the message ID of the temporary error message that occurred during the modification of the statuses.<br>This is returned only if there is a message to be notified.                                                                                                                                                  |

| No. | Member name | Data type | Description                                                                                                                                                                |
|-----|-------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | message     | string    | Returns the body text of the temporary error message that occurred during the modification of the statuses.<br>This is returned only if there is a message to be notified. |

## Notes

- The concurrent execution of a large number of event status change APIs can lead to the degradation of manager performance or cause the manager to time out.
- Before incorporating the execution of the event status change API into your operation, carefully examine how the resulting operation can affect API execution performance and manager performance to ensure that your operational needs are not compromised.

## Examples

The following example uses this API to change the event status of specified events to *Processed*.

Request:

```
POST /im/api/v1/events/status HTTP/1.1
Authorization: Bearer xxxx
Accept-Language: ja
Content-Type: application/json
Accept: application/json
{
  "dealt": "1",
  "sid": [
    "_JP1IM_imhost1/_JP1IMSEQNO_697/_JP1IMEVBSEQNO_746",
    "_JP1IM_imhost1/_JP1IMSEQNO_698/_JP1IMEVBSEQNO_747",
  ]
}
```

Response:

```
HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json
{
  "eventData": [
    {
      "sid": "_JP1IM_imhost1/_JP1IMSEQNO_697/_JP1IMEVBSEQNO_746",
      "value": [
        "E.@JP1IM_DEALT": "1"
      ]
    },
    {
      "sid": "_JP1IM_imhost1/_JP1IMSEQNO_698/_JP1IMEVBSEQNO_747",
      "value": [
        "E.@JP1IM_DEALT": "1"
      ]
    }
  ]
}
```

## 5.6.4 Event generation

### Description

Issues the specified JP1 event and registers it with the manager host (local host). After the registration, the serial number of the issued event is returned.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/events/send httpVersion
```

Request message body

```
{
  "eventId": event-ID,
  "message": message,
  "attrs": {extended-attribute-name:extended-attribute-value[, ...]}
}
```

Response message body

```
serial-number-of-the-issued-event
```

### Parameters

eventId

A basic part event ID to be issued.

Specify it in the following range:

- 0 to 1FFF
- 7FFF8000 to 7FFFFFFF

If a value is out of specifiable range, the KAJY02047-E message is output.

Omitting this parameter causes eventId to be set to 0.

message

Specify message text that describes the JP1 event as a string of 1,023 bytes or smaller. If a string of 1,024 bytes or larger is specified, an exception occurs to exit the process.

Note that the character code of the registered message depends on that of the OS environment in which the manager is located.

However, if the language environment is different from the manager's language setting, multibyte characters cannot be used and are supported within the ASCII character range.

attrs

An extended attribute.

If the same extended attribute name is specified multiple times, this parameter is overwritten by the value of the last specified extended attribute.

Specify the extended attribute name with a string of up to 32 bytes consisting of alphanumeric characters and underscores (starting with an alphabetic letter and having all capital alphabetic letters). If an extended attribute name that contains any unspecifiable string is specified, the KAJY02047-E message is output. In addition, do not use the prefix E . in the extended attribute name. If E . is specified, the KAJY02047-E message is output. The total length of all the extended attribute values you can specify is 10,000 bytes.

The following table lists and describes the event attributes registered by the event registration function.

**Table 5–13: List of event attributes registered by the event registration function**

| No. | Category        | Item name                  | Attribute name | Description of the event attribute value                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|-----------------|----------------------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Basic attribute | Serial number              | SEQNO          | Serial number of the JP1 event to be issued                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 2   |                 | Event ID <sup>#1</sup>     | ID             | Event ID passed through the parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3   |                 | Registered reason          | REASON         | Reason why the event was registered in the current server: <ul style="list-style-type: none"> <li>• 1: The event was issued to the local event server on the current event server.</li> <li>• 2: The event was issued from the current server to a different server (the value cannot be obtained).</li> <li>• 3: The event was issued from a different server to the current server.</li> <li>• 4: The event was transferred from a different server due to the environment setting.</li> </ul> |
| 4   |                 | Source process ID          | PROCESSID      | Process ID of the source API                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 5   |                 | Registered time            | TIME           | Registration time on the source event server                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 6   |                 | Arrived time               | ARRIVEDTIME    | Registration time on the local event server                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 7   |                 | Source user ID             | USERID         | User ID of the source process (Fixed value: -1)                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 32  |          | Individual extended attribute count | Individual extended attribute count | Number of extended attributes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

#1

The following shows the format for database output:

Example: ID:IDEXT 0000000A:00000000

#2

Common attributes are stored in an array. They are not registered if not specified.

The following shows the attribute values of an event registered by this REST API:

-- This parameter is used for execution

```

{
  "eventId":"10000",
  "message":"A failure occurred in the cloud service",
  "attrs":{"SEVERITY":"Error"}
}
SQ 18840099
ID 00010000:00000000
KN 0
HD 0

MS A failure occurred in the cloud service
UP %00%00%00%00%00%00%00%00
XN 1
XV SEVERITY= Error

```

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                       |
|-------------|-------------|-------------------------------------------------------------------|
| 200         | None        | A JP1 event was issued.                                           |
| 400         | KAJY02047-E | The format of the parameter specified for the request is invalid. |
| 403         | KAJY01000-E | There is no permission to run the REST API.                       |
| 500         | KAJY02048-E | A JP1 event could not be issued.                                  |

For details on the messages, see the *JP1/Integrated Management 3 - Manager Messages*.

## Return values

The following information is returned in the response body if the status code is 200:

| Data type | Description                      |
|-----------|----------------------------------|
| Number    | Serial number of an issued event |

## Examples

The following shows a usage example of the event API:

Request:

```

POST http://hostname:20703/im/api/v1/events/send
{
  "eventId":"1FFF",
  "message":"A failure occurred in Service A",
  "attrs":{"SEVERITY":"Error","JP1_SOURCEHOST":"HOSTA"}
}

```

Response:

```
18839936
```

## 5.6.5 JP1 Event converter

### Description

The event information notified by the external system is converted into a JP1 event and issued.

The event information notified by the external system is passed to the product plug-in, and the JP1 event is issued according to the returned JP1 event information.

### Execution permissions

None

### API version

v1

### Format

Request line

```
POST /im/api/v1/events/transform HTTP/1.1
```

Request header

| Header name   | Setting value  |
|---------------|----------------|
| Authorization | Do not set it. |

If message body of the request is in JSON format, the other request headers are the same as Common spec of API. For the request header of Common spec of API, see the explanation of the request header in [5.2.3 Request format](#).

Request message body

You can send it in JSON format. The data structure of the object is arbitrary (using the unique format of each product plug-in).

JP1/IM - For all product plug-ins set in Manager, if the data cannot be converted to JP1 events, try to convert to JP1 events in the following format.

```
[
  {
    "eventId":event ID,
    "message":messag,
    "attrs":{"extendedattribute name:extended attribute value, ...}
  },
  ...
]
```

Response message body

```
{
  "eventSeqNo":[Serial number in the DB of the issued event, ...]
  "exceeddJpleventMaxDetected":Detection of exceeding the upper limit of the number of converted JP1 events,
  "messages":[
    {
      "messageId":"Message ID",
      "message":"message body"
    }
  ]
}
```

```

    },
    ...
  ]
}

```

## Parameters

Here are the parameters that you specify for message body of the request:

| No. | Parameters | Data type | Description                                                         |
|-----|------------|-----------|---------------------------------------------------------------------|
| 1   | eventId#   | string    | Specifies the event ID to be published.                             |
| 2   | message#   | string    | Specifies the message text that describes the content of the event. |
| 3   | attrs#     | Array     | Specifies extended attributes.                                      |

Note #

For details on the contents to be specified for each item, see the parameters of [5.6.4 Event generation](#).

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                           |
|-------------|-------------|-----------------------------------------------------------------------------------------------------------------------|
| 200         | --          | API processing succeeded.                                                                                             |
|             | KAJY67002-W | Communication with JP1/Base Events Service failed.                                                                    |
|             | KAJY67003-W | More than 100 JP1 events were converted.                                                                              |
|             | KAJY67000-W | The retrieved data did not contain the event ID.                                                                      |
|             |             | The retrieved data did not contain a message.                                                                         |
|             |             | Invalid extension attribute specification.                                                                            |
|             |             | The extended attribute name exceeds 32 bytes.                                                                         |
|             |             | The sum of the extended attribute values exceeds 10000 bytes.                                                         |
| 406         | KAJY67001-E | The JP1 event data was not returned from each linked product plug-in, and the data format was not the default format. |

The following information with JSON format is returned in the response body if the status code is 200:

| No. | Member name               | Data type | Description                                                                                                                                                                                        |
|-----|---------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | eventSeqNo                | Object[]  | Returns the DB serial number of the issued event as a string type array.                                                                                                                           |
| 2   | exceedJp1eventMaxDetected | boolean   | Whether or not it is detected that the number of converted JP1 events has exceeded the upper limit. <ul style="list-style-type: none"> <li>true: Detected</li> <li>false: Do not detect</li> </ul> |
| 3   | messages                  | object[]  | An array of messages to be notified.<br>If there is no message to be notified, it is omitted.                                                                                                      |
| 4   | messageId                 | string    | The message ID. If there is no message to be notified, it is omitted.                                                                                                                              |
| 5   | message                   | string    | The message body. The language used is determined by the Accept-Language property specified in the HTTP request header. If there is no message to be notified, it is omitted.                      |

## Examples

The following is an example of using this API using the OSS curl command.

```
>curl -i --header "Accept-Language: ja" --header "Content-Type: application/json" --request POST --data @c:\work\request.json "http://localhost:20703/im/api/v1/events/transform"
```

# 5.7 API for plug-ins

This section describes the API for plug-ins.

## 5.7.1 Plug-in processing execution

### Description

Executes any functional operation for a plug-in.

### Execution permissions

See *Appendix E.1 Operating permissions required for system monitoring using the Intelligent Integrated Management Base* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.  
If you specify `_performanceDataGet` for the method parameter when JP1/PFM is linked, the `Admin` or `Operator` permissions must be granted to the execution user for the resource group of the JP1/PFM agent.

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/actions httpVersions
```

Request message body

```
{
  "method": function-name,
  "sid": target-IM-management-node-SID,
  "args": operation-specification
}
```

Response message body

```
result-of-the-operation
```

### Parameters

method

Specify the name of the plug-in function to execute. A function name starting with double underscores (`__`) is not allowed.  
The following function is provided by default:

| Function name                    | Plug-in         | Operation                       |
|----------------------------------|-----------------|---------------------------------|
| <code>_performanceDataGet</code> | JP1/PFM plug-in | Getting performance information |

sid

Specify the IM management node to be operated with the plug-in, in the SID format of configuration information. Only the IM management node at the end of the system configuration tree can be specified.  
For details on the SID, see [7.1 SID](#).

args

Specify the values to pass to the `args.methodArgs` argument of the plug-in function to execute. If there is no information to be passed, specify an empty object (`{ }`).

The size of specified values must be less than 10 MB including other parameters.

The following table describes what value is passed to `args.methodArgs` when the method parameter is set to `_performanceDataGet`:

| No. | Member name            | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|------------------------|-----------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>recordId</code>  | string    | No       | Specify the record ID to be retrieved. Only uppercase characters can be used.<br>The prefix of the record ID, <code>PI_</code> , <code>PD_</code> , or <code>PL_</code> can be omitted.<br>For example, if the prefix is <code>PI_</code> , you can specify <code>LOGD</code> instead of <code>PI_LOGD</code> .<br>Note that if another record that has a different prefix but has the same record ID excluding the prefix exists, it is assumed that both records are specified.                                                                                                                                                                                                                                                                                                                                                              |
| 2   | <code>fieldIds</code>  | string[]  | Yes      | Specify the fields you get as an array. Only uppercase characters can be used.<br>If you want to get performance data of specific fields, specify the field IDs <sup>#</sup> in array format.<br><br><sup>#</sup><br>The format is <i>record-ID_PFM-Manager-name</i> . For CPU% of the <code>PD_PDI</code> record, the field ID is <code>PD_PDI_PCT_PROCESSOR_TIME</code> . If this member is omitted, all the fields in the specified record are output. If an empty value is specified (that is, <code>fieldIds: [ ]</code> ), it is assumed that this member is omitted.<br>Note that the data below (key field needed to identify the record) is output even if the field ID is omitted. For details on the key fields, see the manual of each agent.<br>- Historical report (single agent)<br>- "Date and Time" field<br>- ODBC key field |
| 3   | <code>startTime</code> | string    | No       | Specify the start date and time of reporting. Use the ISO8601 extended format ( <i>YYYY-MM-DDThh:mm:ssZ</i> ). The letter Z at the end of the time indicates the UTC timezone. In the timezone other than UTC, use the format of <i>+hh:mm</i> or <i>-hh:mm</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 4   | <code>endTime</code>   | string    | No       | Specify the end date and time of reporting.<br>Use the ISO8601 extended format ( <i>YYYY-MM-DDThh:mm:ssZ</i> ) for the date and time of the UTC timezone. The letter Z at the end of the time indicates the UTC timezone. In the timezone other than UTC, use the format of <i>+hh:mm</i> or <i>-hh:mm</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 5   | <code>interval</code>  | string    | No       | Specify the interval of reporting. Use the format below. It is case insensitive.<br><ul style="list-style-type: none"> <li>• MIN: In minutes</li> <li>• HOUR: In hours</li> <li>• WEEK: Weekly</li> <li>• DAY: Daily</li> <li>• MONTH: Monthly</li> <li>• YEAR: Yearly</li> </ul> The interval is ignored when specified for a PD record.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 6   | <code>filter</code>    | object[]  | Yes      | Specify this member if you want to filter the performance data you get by its field value. Filtering is possible for more than one field.<br>If you specify multiple filter conditions, the system retrieves the performance data that meets all the conditions (AND condition).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| No. | Member name        | Data type | Optional | Description                                                                                                                                                                                                                                                                        |
|-----|--------------------|-----------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |                    |           |          | If an empty value is specified (that is, <code>filter: [ ]</code> ), it is assumed that this member is omitted.                                                                                                                                                                    |
| 7   | <code>limit</code> | number    | Yes      | Specify the maximum number of records to be retrieved. The possible values are from 1 to 4320.<br><br>If this member is omitted, it is assumed that the specified value is 4320. Specifying a value other than permitted values generates an error, causing the operation to stop. |

The following table describes the format of the object you specify for `filter`:

| No. | Member name           | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|-----------------------|-----------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>fieldId</code>  | string    | No       | Specify the filter ID of the field to be filtered. Only uppercase characters can be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2   | <code>operator</code> | string    | Yes      | Specify the filter condition for performance data you get. Select one of the following values: <ul style="list-style-type: none"> <li><code>=</code>: The value of the field is equal to <code>value</code>.</li> <li><code>&lt;&gt;</code>: The value of the field is not equal to <code>value</code>.</li> <li><code>&lt;</code>: The value of the field is less than <code>value</code>.</li> <li><code>&lt;=</code>: The value of the field is less than or equal to <code>value</code>.</li> <li><code>&gt;</code>: The value of the field is greater than <code>value</code>.</li> <li><code>&gt;=</code>: The value of the field is greater than or equal to <code>value</code>.</li> </ul> If this member is omitted, it is assumed that <code>=</code> is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3   | <code>value</code>    | string    | No       | Specify the value according to the field format described in the manuals for JP1/PFM - Agent or JP1/PFM - RM. Note the following description for the ranges: <ul style="list-style-type: none"> <li>- Character<br/>The specified value is applied as it is. However, <code>*</code> is handled as a wildcard character.</li> <li>- Integer<br/>An integer must be within the acceptable range of the data type for the field, which is from -2,147,483,648 to 2,147,483,647.<br/>However, the check range of the <code>ulong</code> (unsigned long) data type can be extended by specifying the <code>condExpValueUlongExtension</code> parameter in <code>config.xml</code> for JP1/PFM - Web Console.<br/>For details on the <code>config.xml</code> parameter, see the <i>JP1/Performance Management Reference</i>.</li> <li>- Decimal number<br/>Specify a value within the acceptable range of the data type for the field.<br/>If the format of the target field is float or double, and the field value has four decimal places or more, the value is rounded off to the third decimal place.<br/>If the format of the target field is <code>utime</code> and the field value has seven decimal places or more, the value is rounded off to the sixth decimal place.<br/>For details on the format of the field, see the description of each field in the manuals for JP1/PFM - Agent or JP1/PFM - RM.</li> <li>- Date<br/>Specify the date and time in ISO8601 extended format (<code>YYYY-MM-DDThh:mm:ssZ</code>). The letter <code>Z</code> at the end of the time indicates the UTC timezone. In the timezone other than UTC, use</li> </ul> |

| No. | Member name | Data type | Optional | Description                                                                                                                                                                                                                                                                                                    |
|-----|-------------|-----------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |             |           |          | <p>the format of <code>+hh:mm</code> or <code>-hh:mm</code>. (The time always uses the <code>HH:mm:ss</code> format.)</p> <p>Note that an error occurs if any of control characters, ( ), [ ], &lt;, &gt;, =, and " is contained in the value. The acceptable number of bytes is a maximum of 2,048 bytes.</p> |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                        |
|-------------|-------------|--------------------------------------------------------------------|
| 200         | None        | Plug-in execution succeeded.                                       |
| 400         | KAJY22003-E | The request has a parameter with an invalid format.                |
| 403         | KAJY22004-E | There is no permission to access the specified IM management node. |
| 500         | KAJY22005-E | An error occurred during the plug-in processing.                   |

For details on the messages, see the *JP1/Integrated Management 3 - Manager Messages*.

## Return values

| No. | Member name | Data type | Description                                                                                                                                       |
|-----|-------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | --          | object    | The object in which the execution result of the plug-in processing is stored. The return value of the plug-in function is assigned to the object. |

The following table describes the return value when the `method` parameter is set to `_performanceDataGet`:

| No. | Member name                   | Data type  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|-------------------------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>component</code>        | string     | Component name<br>This is always set to <code>HITACHI/JP1/PEM/CONFINFO</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 2   | <code>productId</code>        | string     | Product ID of the agent whose performance data is to be retrieved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 3   | <code>dataModelVersion</code> | string     | Data model version of the agent whose performance data is to be retrieved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 4   | <code>rc</code>               | number     | Return code <ul style="list-style-type: none"> <li>0: Data was retrieved successfully.</li> <li>1: Data was retrieved successfully but some records were not retrieved due to <code>limit</code>.</li> <li>2: There is no data in the specified period.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 5   | <code>fields</code>           | object[]   | Array of field information objects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 6   | <code>data</code>             | string[][] | <p>Two dimensional array of performance data, in [row data] [column data] format.</p> <p>The output order of the column data guarantees the output order of the field information.</p> <p>The data and time data is returned as the data and time in the UTC timezone in ISO8601 extended format (<code>YYYY-MM-DDThh:mm:ssZ</code>). Any timezone other than UTC is not supported. In addition, if <code>dataType</code> of the output data is one of <code>FLOAT</code>, <code>DOUBLE</code>, or <code>SECTIMEDOUBLE</code> and its value is less than 10 to the negative third power or greater than or equal to 10 to the seventh power, the value is output in floating point format (such as <code>1.01E10</code>).</p> |

The following table describes the format of the field information object:

| No. | Member name | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 4   | keyType     | string    | Key attribute of the field needed for identifying data (record) <sup>#2</sup> <ul style="list-style-type: none"> <li>• DATE<br/>It must be specified in one field of all fields, and indicates that the field is a key to identifying the time.</li> <li>• INST<br/>It is specified in zero or more fields of all fields, and indicates that the field is a key specific to data (record).</li> <li>• NONE<br/>It indicates that the field is not a key.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

#1

The point in time serving as a reference depends on the fields. See each field (field in utime format) of JP1/PFM - Agent or JP1/PFM - RM.

#2

The following table lists the combination of key attributes required to identify the data (record):

| Report type                         | Record type       | Combination of attributes required for data identification               |
|-------------------------------------|-------------------|--------------------------------------------------------------------------|
| Historical report<br>(Single agent) | Single row record | <ul style="list-style-type: none"> <li>• DATE</li> </ul>                 |
|                                     | Multi-row record  | <ul style="list-style-type: none"> <li>• DATE</li> <li>• INST</li> </ul> |

## Examples

The example below uses the API in the following scenario:

- The functionality to use: JP1/PFM plug-in for getting performance information
- JP1/PFM manager host name: mgrhost1
- JP1/PFM agent host name: agenthost1

- Target IM management node: JP1/Performance Management - Agent Option for Platform (For Windows)
- The monitoring item to be retrieved: CPU usage
- Output start time: April 1, 2017 00:00:00 JST
- Output end time: April 1, 2017 01:00:00 JST

Request:

```
POST /im/api/v1/actions HTTP/1.1
Authorization:Bearer xxxx
Accept-Language: ja
Content-Type: application/json
Accept: application/json
{
  "method": "_performanceDataGet",
  "sid": "_JP1PFM-M_MGRHOST1/_JP1PFM-AHOST_AGENTHOST1/_HOST_AGENTHOST1/_JP1PFM-A_TAlagenthost1",
  "args": {
    "recordId": "PI",
    "fieldIds": ["PI_PCT_TOTAL_PROCESSOR_TIME"],
    "startTime": "2017-04-01T00:00:00+09:00",
    "endTime": "2017-04-01T01:00:00+09:00",
    "interval": "HOUR"
  }
}
```

Response:

```
{

## 5.8 API for system status monitoring

---

This section describes operations for API of system status monitoring.

### 5.8.1 IM management node related information generation

#### Description

Obtain the product-managed configuration from JP1/AJS3, JP1/PFM, JP1/IM and JP1/Base, and use the following file to generate configuration management tree File:

- System node definition file (imdd\_systemnode.conf)
- Category name definition file for IM management nodes (imdd\_category\_name.conf)
- Target host definition file for configuration collection (imdd\_target\_host.conf)
- Host name definition file (imdd\_host\_name.conf)

The storage directory of files created by this API is as follows.

In Windows:

- For a physical host:  
*Manager-path*\tmp\imdd\imnode\data
- For a logical host:  
*shared-folder*\JP1IMM\tmp\imdd\imnode\data

In Linux:

- For a physical host:  
/var/opt/jplimm/tmp/imdd/imnode/data
- For a logical host:  
*shared-directory*/jplimm/tmp/imdd/imnode/data

If the generation is successful, the JP1 event "3F80" is issued, and if the generation fails, the "3F81" is issued.

#### Execution permissions

Following permissions are required:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

#### API version

v1

#### Format

Request line

```
POST /application/component/apiVersion/nodes/create httpVersion
```

Request message body

None

Response message body

For normal termination, there is no response.

For termination with warning, the following response is returned.

```

{
  "returnCode": return-code,
  "messageList": [
    {
      "messageId": message-ID,
      "message": message
    },
    ...
  ]
}

```

## Parameters

None

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message                | Description                                                                                                                                                                                     |
|-------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | OK                     | Success.                                                                                                                                                                                        |
| 400         | Bad Request            | The request header is invalid.                                                                                                                                                                  |
| 403         | Forbidden              | You do not have execute permission.                                                                                                                                                             |

| 500         | Internal Server Error  | The server operation error occurred.                                                                                                                                                            |
| 503         | Service Unavailable    | Service is not available.<br>The service is temporarily unavailable due to overload or maintenance.<br>It is returned when a temporary error occurs (when it is expected to improve over time). |

## Return values

| Return values | Description                                        |
|---------------|----------------------------------------------------|
| 2             | Exclusive locking is in progress.                  |
| 6             | Execute of this API does not have enough data.     |
| 9             | The path of the storage directory is too long.     |
| 13            | A required file does not exist.                    |
| 14            | A required file could not be read.                 |
| 15            | A required file has an invalid format.             |
| 16            | A required file has an invalid description.        |
| 17            | Invalid information was received from the plug-in. |
| 18            | Information from the plug-in is invalid.           |
| 20            | Failed to create IM management node file.          |
| 21            | Failed to create IM management node link file.     |

| Return values | Description                                                    |
|---------------|----------------------------------------------------------------|
| 23            | Failed to create IM management node tree file.                 |
| 26            | The user used for authentication has insufficient permissions. |
| 255           | The system error.                                              |

## Examples

The following is a sample API that generates a configuration management tree file:

Request:

```
POST /im/api/v1/nodes/create HTTP/1.1
Authorization: Bearer anAxYWRtaW46TUdGa01tTTJNMlV3TURFNh6STNYekE0T2pJME9qTXpYMTlmWDE5ZlgxOWZYMtImWDE5ZlgycHdNV0ZrYlJQWdJQ0FnSUNBZ01DQWdJQ0FnSUNBZ01DQWdJQ0Fn
Accept-Language: ja
Content-Type: application/json
Accept: application/json
```

Response:

```
HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json
```

## 5.8.2 IM management node related information reflection

### Description

The following file obtained by the IM Management Node Related Information Generation API and the IM Management Node Link Definition File are used to create the configuration management tree.:

- IM management node tree file
- IM management node data files
- IM management node link file

If the new/rebuild mode is specified as the import method, all JP1 events stored in the integrated management database are acquired and evaluated, and the status of each IM management node is evaluated.

When the configuration change mode is specified for the import method, no JP1 events are acquired from the integrated monitoring DB and IM management node status information and event information related to IM management node that are already retained are inherited for use.

The directory where files created by the IM Management Node Related Information Generation API are stored is as follows.

In Windows:

- For a physical host:  
*Manager-path\tmp\imdd\imnode\data*
- For a logical host:  
*shared-folder\JP1IMM\tmp\imdd\imnode\data*

In Linux:

- For a physical host:  
`/var/opt/jplimm/tmp/imdd/imnode/data`
- For a logical host:  
`shared-directory/jplimm/tmp/imdd/imnode/data`

In addition, JP1 event "3F82" is issued if reflection is successful, and "3F83" is issued if reflection fails.

## Execution permissions

Following permissions are required:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

## API version

v1

## Format

Request line

```
POST /application/component/apiVersion/nodes/update httpVersion
```

Request message body

```
{
  "mode": import-method
}
```

Response message body

For normal termination, there is no response.

For termination with warning, the following response is returned.

```
{
  "returnCode": return-code,
  "messageList": [
    {
      "messageId": message-ID,
      "message": message
    },
    ...
  ]
}
```

## Parameters

Here are the parameters that you specify for message body of the request:

| Parameter name | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                    |
|----------------|-----------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mode           | string    | Yes      | <p>Specify the import method.</p> <ul style="list-style-type: none"><li>• reconfigure<br/>Reflect in the new/rebuild mode.</li><li>• change<br/>Reflect in the configuration change mode.</li></ul> <p>By default, it follows setting value of <code>jpl.imdd.simt.updateMode</code> property of Intelligent Integrated Management Base definition file (imdd.properties).</p> |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message                | Description                                                                                                                                                                                     |
|-------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | OK                     | Success.                                                                                                                                                                                        |
| 400         | Bad Request            | The request header is invalid.                                                                                                                                                                  |
| 403         | Forbidden              | There is no execution permission.                                                                                                                                                               |
| 404         | Not Found              | The resource could not be found.                                                                                                                                                                |
| 406         | Not Acceptable         | An invalid Accept or Accept-Language header is specified.                                                                                                                                       |
| 408         | Request Timeout        | The request timed out.                                                                                                                                                                          |
| 415         | Unsupported media type | An invalid Content-Type header is specified.                                                                                                                                                    |
| 500         | Internal Server Error  | An error occurred with the server processing.                                                                                                                                                   |
| 503         | Service Unavailable    | Service is not available.<br>The service is temporarily unavailable due to overload or maintenance.<br>It is returned when a temporary error occurs (when it is expected to improve over time). |

## Return values

| Return values | Description                                                                 |
|---------------|-----------------------------------------------------------------------------|
| 2             | Exclusive locking is in progress.                                           |
| 3             | Invalid argument.                                                           |
| 6             | Execute of this API does not have enough data.                              |
| 9             | The storage directory path is too long.                                     |
| 10            | JP1/IM - Manager database service is not running.                           |
| 13            | A required file does not exist.                                             |
| 14            | A required file could not be read.                                          |
| 15            | A required file has an invalid format.                                      |
| 16            | A required file has an invalid description.                                 |
| 17            | Failed to get event information.                                            |
| 19            | Invalid information was received from the plug-in.                          |
| 22            | Failed to replace master file.                                              |
| 26            | The user used for authentication has insufficient permissions.              |
| 27            | There are suggestion definitions that do not map to any IM management node. |
| 28            | Failed to create proposal related master file.                              |
| 29            | Suggestion-related master file replacement failed.                          |
| 255           | The system error.                                                           |

## Examples

Here is a sample API that recreates configuration management tree, retrieves and evaluates all of JP1 events stored in the integrated administration DB, and reflects the status of the configuration objects in the tree that you created.

#### Request:

```
POST /im/api/v1/nodes/update HTTP/1.1
Authorization: Bearer anAxYWRtaW46TUdGa01tTTJNMlV3TURFNh6STNYeke0T2pJM
E9qTXpYMTlmWDE5ZlgxOWZyMTlmWDE5ZlgycHdNV0ZrYldsU1DQWdJQ0FnSUNBZ01DQWdJ
Q0FnSUNBZ01DQWdJQ0Fn
Accept-Language: ja
Content-Type: application/json
Accept: application/json

{
  "mode": "reconfigure"
}
```

#### Response:

```
HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json
```

## 5.8.3 IM management node information acquisition

### Description

Gets the IM management node information collected from JP1/AJS3, JP1/PFM, JP1/IM, JP1/Base, and others. It can get all IM management node information, regardless of view permissions of the logged-in JP1 user.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API version

v1

### Format

#### Request line

```
GET /application/component/apiVersion/nodes/configInfo httpVersion
```

#### Request message body

None.

#### Response message body

```
{
  "simtData": [
    IM-management-node-information-object, ...
  ]
}
```

### Parameters

None.

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message                | Description                                                    |
|-------------|------------------------|----------------------------------------------------------------|
| 200         | OK                     | The IM management node information was retrieved successfully. |
| 400         | Bad Request            | The request header is invalid.                                 |
| 401         | Unauthorized           | Authentication is required.                                    |
| 403         | Forbidden              | There is no execution permission.                              |
| 404         | Not Found              | The resource could not be found.                               |
| 406         | Not Acceptable         | An invalid Accept or Accept-Language header is specified.      |
| 412         | Precondition failed    | The server cannot be accessed.                                 |
| 415         | Unsupported media type | An invalid Content-Type header is specified.                   |
| 500         | Internal Server Error  | An error occurred with the server processing.                  |

## Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                                                                                                                                                                    |
|-----|-------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | simtData    | object[]  | Returns an array of the IM management node information objects that contain collected IM management node information.<br>A zero-length array is returned if no IM management node information. |

## Examples

The following example uses this API to get IM management node information.

Note that the value of the Authorization header must be specified in a single line.

Request:

```
GET /im/api/v1/nodes/configInfo HTTP/1.1
Authorization: Bearer xxxx
Accept-Language: ja
Content-Type: application/json
Accept: application/json
```

Response:

```
HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json

{
  "simtData": [
    { "sid": "_JP1AJS-M_host1/_HOST_host1", "value": {...} },
    { "sid": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_schedulerserv", "value": {...} },
    { "sid": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_schedulerserv/_JP1JOBG_jobgroup", "value": {...} },
    { "sid": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_schedulerserv/_JP1JOBG_jobgroup", "value": {...} }
  ]
}
```

```

    _jobgroup/_JP1ROOTJOBNET_jobnet1","value":{...}},
    {"sid": "_JP1AJS-M_host1/_JP1AJS-A_AGT10/_HOST_host10","value":{...}
  },
  {"sid": "_JP1PFM-M_host2/_HOST_host2","value":{...}},
  {"sid": "_JP1PFM-M_host2/_JP1PFM-A_servid/_HOST_host20","value":{...
}}
]
}

```

## 5.8.4 Configuration management tree information acquisition

### Description

Gets tree information that is displayed in the status monitoring functionality of the Intelligent Integrated Management Base. IM management node tree information cannot be retrieved if the logged-in JP1 user has no permission to view the tree information.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API version

v1

### Format

Request line

```
GET /application/component/apiVersion/nodes/treeInfo httpVersion
```

Request message body

None.

Response message body

```

{
  "simtData ":[
    IM-management-node-tree-information-object,...
  ]
}

```

### Parameters

None.

### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message      | Description                                                         |
|-------------|--------------|---------------------------------------------------------------------|
| 200         | OK           | The IM management node tree information was retrieved successfully. |
| 400         | Bad Request  | The request header is invalid.                                      |
| 401         | Unauthorized | Authentication is required.                                         |
| 403         | Forbidden    | There is no execution permission.                                   |

| Status code | Message                | Description                                               |
|-------------|------------------------|-----------------------------------------------------------|
| 404         | Not Found              | The resource could not be found.                          |
| 406         | Not Acceptable         | An invalid Accept or Accept-Language header is specified. |
| 412         | Precondition failed    | The server cannot be accessed.                            |
| 415         | Unsupported media type | An invalid Content-Type header is specified.              |
| 500         | Internal Server Error  | An error occurred with the server processing.             |

## Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                                                                                                                                                                                                                                                                                                                            |
|-----|-------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | simtData    | object[]  | Returns an array of IM management node tree information objects that contain collected IM management node tree information.<br>A zero-length array is returned if no IM management node tree information is available.<br>For details on the IM management node tree information object, see <a href="#">7.2.2(1) IM management node tree object</a> . |

## Examples

The following example uses this API to get IM management node tree information.

Note that the value of the Authorization header must be specified in a single line.

Request:

```
GET /im/api/v1/nodes/treeInfo HTTP/1.1
Authorization: Bearer xxxx
Accept-Language: ja
Content-Type: application/json
Accept: application/json
```

Response:

```
HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json

{
  "simtData": [
    { "sid": "_ROOT_AllSystems", "value": { "target": [], "label": "All Systems" } },

        {"sid": "_ROOT_AllSystems/_SYSTEM_System1/_SYSTEM_SubSystem1/_HOST_host1/_CATEGORY_job/_OBJECT_JP1AJSMJOB/_OBJECT_ScheduleServ/_OBJECT_jobgroup/_OBJECT_jobnet1", "value": {"target": [], "label": "jobnet1", ...}}
    ]
}

```

## 5.8.5 IM management node status acquisition

### Description

Gets the status information of all IM management nodes (management groups or management objects). If you specify IM management nodes as a parameter, the status information of only the specified IM management nodes is retrieved. If the IM management node that the logged-in JP1 user has no permission to view is specified, zero-length array is returned.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API version

v1

### Format

#### Request line

```
POST /application/component/apiVersion/nodes/treeInfo/status httpVersion
```

#### Request message body

```

{
    "sid": [
        "IM-management-node-tree-SID"., ...
    ]
}

```

#### Response message body

```

{
    "simtData": [
        status-information-object, ...
    ]
}

```

## Parameters

`sid`

Specify the tree SID of the IM management node. You can get the status information of the specified IM management nodes. For details on the SID, see [7.1 SID](#).

This parameter accepts multiple values.

Omitting this parameter causes the status information of all accessible IM management nodes to be retrieved.

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message                | Description                                                                 |
|-------------|------------------------|-----------------------------------------------------------------------------|
| 200         | OK                     | The status of IM management nodes was retrieved successfully.               |
| 400         | Bad Request            | The request header is invalid.                                              |
| 401         | Unauthorized           | Authentication is required.                                                 |
| 403         | Forbidden              | There is no execution permission.                                           |
| 404         | Not Found              | There is no permission to access the resource or the resource is not found. |
| 406         | Not Acceptable         | An invalid Accept or Accept-Language header is specified.                   |
| 412         | Precondition failed    | The server cannot be accessed.                                              |
| 415         | Unsupported media type | An invalid Content-Type header is specified.                                |
| 500         | Internal Server Error  | An error occurred with the server processing.                               |

## Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name           | Data type             | Description                                                                                                                                                                                                                      |
|-----|-----------------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>simtData</code> | <code>object[]</code> | Returns the retrieved status information as an array of the status information objects.<br>A zero-length array is returned if no IM management node is found for the specified identifier or no IM management node is available. |

## Definition format

```
{
  simtData: [
    {
      "sid": "SID-of-the-tree",
      "value": {
        "status": { "JP1EVENT": status-value }
      }
    },
    ...
  ]
}
```

## Members

The following table describes the members:

| No. | Member name | Data type | Description                                                                                                                   |
|-----|-------------|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| 1   | simtData    | array     | An array that stores the status information                                                                                   |
| 2   | sid         | string    | The SID of the tree for the IM management node                                                                                |
| 3   | value       | array     | An array that stores the status values                                                                                        |
| 4   | status      | string    | The status of the SID for the IM management node<br>The type of the status (JP1EVENT) and a number that represents the status |

Only simtData objects that are on the tree nodes whose status has been changed more than once due to JP1 events or higher-level propagation in the tree nodes specified by the request parameter will be returned.

The status values mean:

- 40: An Emergency-, Alert-, Critical-, or less-severe-level event occurred but was not processed.
- 30: An Error- or less-severe-level event occurred but was not processed.
- 20: A Warning- or less-severe-level event occurred but was not processed.
- 10: All the applicable severe events have been processed (or canceled or removed), and the system is in a healthy condition.

## Examples

The following example uses the API to get the status of a management object, which is a jobnet with the SID of \_JP1AJS-M\_host1/\_HOST\_host1/\_JP1SCHE\_schedulerserv/\_JP1JOBG\_jobgroup/\_JP1ROOTJOBNET\_jobnet1.

Note that the value of the Authorization header must be specified in a single line.

Request:

```
POST /im/api/v1/nodes/treeInfo/status HTTP/1.1
Authorization: Bearer xxxx
Accept-Language: ja
Content-Type: application/json
Accept: application/json

{
  "sid": [
    "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_schedulerserv/_JP1JOBG_jobgro
up/_JP1ROOTJOBNET_jobnet1"
  ]
}
```

Response:

```
HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json

{
  "simtData": [
    {
      "sid": "_ROOT_AllSystem",
      "value": {
        "status": {"JP1EVENT": 40}
      }
    }
  ]
}
```

```
]
}
```

### 5.8.6 Suggestion mapping information acquisition

**Description**

Gets the suggestion definition mapping information, which maps the information of the configuration management tree to the suggestion definition information.

**Execution permissions**

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

**API version**

v1

**Format**

Request line

```
GET /application/component/apiVersion/nodes/treeInfo/suggestions httpVersion
```

Request message body

None.

Request message body

```
{
  "simtData": [
    {
      "sid": tree-SID,
      "value": {
        "suggestionIds": [suggestion-ID, ...]
      }
    },
    ...
  ]
}
```

**Parameters**

None.

**Status codes**

The following table describes the status codes that may be returned as a response to a request:

| Status code | Message     | Description                                                              |
|-------------|-------------|--------------------------------------------------------------------------|
| 200         | None        | The suggestion definition mapping information was successfully acquired. |
| 403         | KAJY01000-E | The logged-in user does not have the permission to execute the REST API. |

**Return values**

The following information is returned in the response body if the status code is 200:

| No. | Member name |               | Data type | Description                                                                                                                                                                                                                                                                                                      |
|-----|-------------|---------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | simtData    |               | object[]  | Returns the acquired suggestion definition mapping information as an array. However, information of a tree SID to which no suggestion definition is mapped is not returned.<br>When neither the <code>jddupdatetree</code> nor <code>jddupdatesuggestion</code> command is executed, an empty array is returned. |
| 2   |             | sid           | string    | Specifies the tree SID of the IM management node.                                                                                                                                                                                                                                                                |
| 3   |             | value         | object    | Additional information of the tree SID.                                                                                                                                                                                                                                                                          |
| 4   |             | suggestionIds | string[]  | An array of the suggestion IDs that are mapped to the tree SID.<br>Even if the logged-in user is not allowed to view some suggestion definitions, the suggestion IDs corresponding to such definitions are returned.                                                                                             |

## Examples

The following example shows how to use this API:

Request:

```
GET http://hostname:20703/im/api/v1/nodes/treeInfo/suggestions
```

Response:

```
HTTP/1.1 200 OK
Content-Type: application/json
{
  "simtData": [
    {
      "sid": "_ROOT_AllSystems/_HOST_HISOL_host1/_CATEGORY_job/_OBJECT_JP1AJSMJOB",
      "value": {
        "suggestionIds": ["suggestion1", "suggestion2"]
      }
    },
    ...
  ]
}
```

## 5.9 API for proxy

---

This section describes operations for proxy.

### 5.9.1 Proxy credential setup

#### Description

Sets up credentials of the proxy server when a REST API is executed from a user-created plug-in on the Intelligent Integrated Management Base. No setup is needed if proxy authentication is not necessary. The information you specify takes effect immediately in the Intelligent Integrated Management Base.

#### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator

#### API version

v1

#### Format

Request line

```
POST /application/component/apiVersion/proxyUsers httpVersion
```

Request message body

```
{
  "op": operation,
  "id": user-id,
  "pw": password
}
```

Response message body<sup>#</sup>

```
{
  "userIdList": [
    "user-id", ...
  ]
}
```

<sup>#</sup>: If list is specified for the op parameter

#### Parameters

op

Specifies the operation. This parameter cannot be omitted.

- list  
Returns the proxy server authentication information configured in the Intelligent Integrated Management Base.
- add  
Updates the proxy server authentication information in the Intelligent Integrated Management Base.
- rm

Removes the proxy server authentication information configured in the Intelligent Integrated Management Base.

`id`

Specifies the user ID for proxy server authentication. You do not have to specify it if `list` is specified for `op` parameter.

`pw`

Specifies the password for the user ID for proxy server authentication.  
You do not have to specify it if `list` or `rm` is specified for `op` parameter.

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                                    |
|-------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | None        | Processing of the proxy authentication information REST API was successful.                                                                    |
| 400         | KAJY52012-E | The proxy authentication information REST API cannot be executed due to an invalid parameter of the proxy authentication information REST API. |
| 403         | KAJY01000-E | There is no permission to run the REST API.                                                                                                    |
| 500         | KAJY52013-E | The proxy credentials failed to be exclusive.                                                                                                  |
|             | KAJY52014-E | The proxy credentials failed to be configured.                                                                                                 |

## Return values

The following information is returned in the response body if the status code is 200:

The return value varies depending on what is specified for the `op` parameter.

- In `list`

| No. | Member name             | Data type | Description                           |
|-----|-------------------------|-----------|---------------------------------------|
| 1   | <code>userIdList</code> | array     | List of proxy authentication user IDs |

- In `add` or `rm`

None.

The size of the message body of a response is 0 bytes.

| Return values | Description                    |
|---------------|--------------------------------|
| 2             | Exclusive locked               |
| 3             | Invalid argument               |
| 7             | Request processing is underway |
| 13            | Update failure error           |
| 255           | System error                   |

## Note

This API cannot be executed simultaneously. An error occurs if it is executed.

## Examples

The following shows a usage example of the proxy credential setup API.

**Request:**

```
POST http://hostname:20703/im/api/v1/proxyUsers
{
  "op": "list"
}
```

**Response:**

```
{
  "userIdList": [
    "user001", "user002", ...
  ]
}
```

# 5.10 API for linked product

This section describes operations for linked product.

## 5.10.1 URL information acquisition

### Description

Gets the URL to start the monitor window of a linked product that corresponds to the SID of the specified IM management node. Executing this API returns the URL via the `__urlGet` method of the user-created plug-in. For details on the `__urlGet` method, see [4.4.4\(11\) `\_\_urlGet` method](#).

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/nodes/monitorUrl httpVersion
```

Request message body

```
{
  "sid": IM-management-node-SID
}
```

Response message body

```
{
  urlList:[
    {
      "url": URL-for-starting-the-monitor,
      "name": display-name-of-the-URL
    },
    ...
  ]
}
```

### Parameters

sid

Specifies the SID (management object ID). This parameter cannot be omitted.

### Status codes

| Status code | Message     | Description                                                                                                                          |
|-------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 200         | None        | Processing of the URL information acquisition REST API was successful.                                                               |
| 400         | KAJY02049-E | The URL information acquisition REST API cannot be executed due to an invalid parameter of the URL information acquisition REST API. |

| Status code | Message     | Description                                 |
|-------------|-------------|---------------------------------------------|
|             | KAJY22011-E | A nonexistent SID has been specified.       |
| 403         | KAJY01000-E | There is no permission to run the REST API. |
| 500         | KAJY02050-E | An attempt to obtain the URL failed.        |

## Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                                                                                                                                  |
|-----|-------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | urlList     | object[]  | The obtained URL information is returned as an array. If the URL that corresponds to the specified SID does not exist, an array with 0 elements is returned. |
| 2   | url         | string    | Specifies the URL for starting the linked product.                                                                                                           |
| 3   | name        | string    | Specifies the display name of the URL.                                                                                                                       |

## Examples

The following shows a usage example of the API to get the URL for starting the monitor of a jobnet (sid:\_JP1AJS-M\_host1/\_HOST\_host1/\_JP1SCHE\_schedulerserv/\_JP1JOBG\_jobgroup/\_JP1ROOTJOBNET\_jobnet1) that is a management object.

Request:

```
POST http://hostname:20703/im/api/v1/nodes/monitorUrl
{
  "sid": "_JP1AJS-M_host1/_HOST_host1/_JP1SCHE_schedulerserv/_JP1JOBG_jobgroup/_JP1ROOTJOBNET_jobnet1"
}
```

Response:

```
{
  urlList: [
    {
      "url": "http://xxx.xxx.xxx.xxx:22252/ajs/...",
      "name": "JP1/AJS3 - Web Console (List)"
    }
  ]
}
```

# 5.11 API for trends

This section describes operations for trends.

## 5.11.1 Metric list acquisition

### Description

Gets the list of metrics for time-series data that can be obtained through the SID of the specified IM management node.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/nodes/metrics httpVersion
```

Request message body

```
{
  "sid": IM-management-node-SID
}
```

Response message body

```
{
  "metrics": [
    {
      "name": metric,
      "label": metric-display-name,
      "category": category-of-the-metric,
      "description": description-of-the-metric,
      "default": default-setting
    }
    ...
  ]
}
```

### Parameters

sid

Specifies the SID (management object ID). This parameter cannot be omitted.

### Status codes

| Status code | Message | Description                                                        |
|-------------|---------|--------------------------------------------------------------------|
| 200         | None    | Processing of the metric list acquisition REST API was successful. |

| Status code | Message     | Description                                                                                                                  |
|-------------|-------------|------------------------------------------------------------------------------------------------------------------------------|
| 400         | KAJY22009-E | The metric list acquisition REST API cannot be executed due to an invalid parameter of the metric list acquisition REST API. |
|             | KAJY22011-E | A nonexistent SID has been specified.                                                                                        |
| 403         | KAJY01000-E | There is no permission to run the REST API.                                                                                  |
| 500         | KAJY22007-E | An attempt to obtain the list of metrics failed.                                                                             |
|             | KAJY22008-E | The obtained data is invalid.                                                                                                |

## Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                                                                                                                                         |
|-----|-------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | metrics     | object[]  | The list of obtained metrics is returned as an array.                                                                                                               |
| 2   | name        | string    | Is filled with the metric name.                                                                                                                                     |
| 3   | label       | string    | Is filled with the display name of the metric.<br>If not specified, it is omitted.                                                                                  |
| 4   | category    | string    | Is filled with the category for the metric.<br>If not specified, it is omitted.                                                                                     |
| 5   | description | string    | Is filled with the description of the metric.<br>If not specified, it is omitted.                                                                                   |
| 6   | default     | boolean   | Is filled with whether it is the default metric name. <ul style="list-style-type: none"> <li>• true: Default metric</li> <li>• false: Non-default metric</li> </ul> |

## Examples

The following shows a usage example of the API to get the list of metrics for a service (sid: \_JP1PFM-M\_HOST2/\_JP1PFM-AHOST\_HOST20/\_HOST\_HOST20/\_JP1PFM-A\_serviceID) of a PFM agent that is a management object.

Request:

```
POST http://hostname:20703/im/api/v1/nodes/metrics
{
  "sid": "_JP1PFM-M_HOST2/_JP1PFM-AHOST_HOST20/_HOST_HOST20/_JP1PFM-A_serviceID"
}
```

Response:

```
{
  "metrics": [
    {
      "name": "cpu_used_rate",
      "label": "CPU usage",
      "description": "Processor usage (%). Percentage of the elapsed time where the processor used a thread that is not idle. (Units: %)",
      "default": true
    } ...
  ]
}
```

## 5.11.2 Time-series data acquisition

### Description

Gets time-series data that corresponds to the SID and metric of the specified IM management node.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API version

v1

### Format

#### Request line

```
POST /application/component/apiVersion/nodes/timeSeries httpVersion
```

#### Request message body

```
{
  "sid": IM-management-node-SID
  "metric": metric-name,
  "startTime": start-time,
  "endTime": end-time,
  "countPerInstance": upper-limit-for-the-number-of-data-sets-per-instance,
  "instanceCount": upper-limit-for-the-number-of-instances,
}
```

#### Response message body

```
{
  "metric": "metric",
  "timeSeriesData": [
    {
      "instance": "instance-name",
      "unit": "unit",
      "data": [
        {"time": "time", "value": value},
        ...
      ]
    },
    ...
  ],
  "exceedCountDetected": {
    "countPerInstance": whether-an-excess-of-the-upper-limit-for-the-number-of-data-sets-per-instance-is-detected,
    "instanceCount": whether-an-excess-of-the-upper-limit-for-the-number-of-instances-is-detected
  },
  "messageId": "message-id",
  "message": "message"
}
```

## Parameters

`sid`

Specifies the SID (management object ID). This parameter cannot be omitted.

`metric`

Specifies the metric to be obtained. This parameter cannot be omitted.

Specify it with half-width alphanumeric characters and the following symbols from 1 to 255 characters:

- (hyphen), \_ (underscore)

`startTime`

Specifies the start time of time-series data as the UTC time in ISO8601 format. This parameter cannot be omitted.  
The number of seconds after the decimal point cannot be specified.

`endTime`

Specifies the endtime of time-series data as the UTC time in ISO8601 format. This parameter cannot be omitted.  
The number of seconds after the decimal point cannot be specified.

`countPerInstance`

Specifies the upper limit for the number of data sets per instance to be obtained. The range is from 1 to 30,000.  
Specify it so that the value obtained by multiplying `countPerInstance` parameter by `instanceCount` parameter is less than or equal to 30,000. Omitting this parameter causes the parameter to be set to 60.

`instanceCount`

Specifies the upper limit for the number of instances to be obtained. The range is from 1 to 30,000. Specify it so that the value obtained by multiplying `countPerInstance` parameter by `instanceCount` parameter is less than or equal to 30,000. Omitting this parameter causes the parameter to be set to 10.

## Status codes

| Status code | Message     | Description                                                                                                                            |
|-------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 200         | None        | Processing of the time-series data acquisition REST API was successful.                                                                |
|             | KAJY22012-W | Data that is not returned exists because the upper limit value is exceeded.                                                            |
| 400         | KAJY22010-E | The time-series data acquisition REST API cannot be executed due to an invalid parameter of the time-series data acquisition REST API. |
|             | KAJY22011-E | A nonexistent SID has been specified.                                                                                                  |
| 403         | KAJY01000-E | There is no permission to run the REST API.                                                                                            |
| 500         | KAJY22006-E | An attempt to obtain time-series data failed.                                                                                          |
|             | KAJY22008-E | The obtained data is invalid.                                                                                                          |

## Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name                 | Data type             | Description                                                           |
|-----|-----------------------------|-----------------------|-----------------------------------------------------------------------|
| 1   | <code>timeSeriesData</code> | <code>object[]</code> | The obtained time-series data is returned as an array.                |
| 2   | <code>metric</code>         | <code>string</code>   | Is filled with the metric name.                                       |
| 3   | <code>instance</code>       | <code>string</code>   | Is filled with the instance name.<br>If not specified, it is omitted. |
| 4   | <code>unit</code>           | <code>string</code>   | Is filled with the unit of the metric.                                |
| 5   | <code>data</code>           | <code>object[]</code> | The time and value data is returned as an array.                      |

| No. | Member name         | Data type | Description                                                                                                                                                                                                          |
|-----|---------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6   | time                | string    | The time of time-series data is specified as the UTC time in ISO8601 format. The number of seconds after the decimal point is not specified.                                                                         |
| 7   | value               | number    | The data value is specified.                                                                                                                                                                                         |
| 8   | exceedCountDetected | object    | Whether to detect an excess of the upper limit of the specified parameter value. It has a member for each parameter.                                                                                                 |
| 9   | countPerInstance    | boolean   | Whether to detect an excess of the upper limit for the number of data sets per instance: <ul style="list-style-type: none"> <li>• true: Exceeded</li> <li>• false: Not exceeded</li> </ul>                           |
| 10  | instanceCount       | boolean   | Whether the number of instances exceeds the upper limit. <ul style="list-style-type: none"> <li>• true: Exceeded</li> <li>• false: Not exceeded</li> </ul>                                                           |
| 11  | messageId           | string    | The message ID.<br>This is returned only if there is a message to be notified.                                                                                                                                       |
| 12  | message             | string    | The message body.<br>The used language is determined by the value specified for the <code>Accept-Language</code> property in the HTTP request header.<br>This is returned only if there is a message to be notified. |

## Examples

The following shows a usage example of the API to get time-series data of a service (sid: `_JP1PFM-M_HOST2/_JP1PFM-AHOST_HOST20/_HOST_HOST20/_JP1PFM-A_serviceID`) of a PFM agent that is a management object.

Request:

```
POST http://hostname:20703/im/api/v1/nodes/timeSeries
{
  "sid": "_JP1PFM-M_HOST2/_JP1PFM-AHOST_HOST20/_HOST_HOST20/_JP1PFM-A_
serviceID",
  "metric": "cpu_used_rate",
  "startTime": "2019-05-22T00:00:00Z",
  "endTime": "2019-05-22T01:00:00Z",
  "countPerInstance": 60,
  "instanceCount": 10
}
```

Response:

```
{
  "metric": "cpu_used_rate",
  "timeSeriesData": [
    {
      "unit": "%",
      "data": [
        {"time": "2019-05-22T00:00:00Z", "value": 14.04},
        ...
      ]
    }
  ],
  "exceedCountDetected": {
    "countPerInstance": true,
  }
}
```

```
        "instanceCount": false
    }
}
```

## 5.11.3 Write Trend Data

### Description

Write trend data to the trend data management DB.

Specify the data to be written in JSON format.

### Execution permissions

None

### API version

v1

### Format

#### Request line

```
POST /im/api/v1/trendData/write HTTP/1.1
```

#### Request header

| Header name   | Setting value  |
|---------------|----------------|
| Authorization | Do not set it. |

If message body of the request is in JSON format, the other request headers are the same as Common spec of API.

For the request header of Common spec of API, see the explanation of the request header in [5.2.3 Request format](#).

#### Request message body

You can send it in the JSON format shown below.

```
{
  "labels":{"__name__": "metric name", "label name": "label value", .
..},
  "samples":[
    [time, value],
    ...
  ]
}
{
  "labels":{"__name__": "metric name", "label name": "label value", .
..},
  "samples":[
    [time, value],
    ...
  ]
}
...
```

#### Response message body

None

### Parameters

Here are the parameters that you specify for message body of the request:

| No. | Parameters  | Data type | Description                                                                                                                                                                                                                 |
|-----|-------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | labels      | Array     | Specify the labels for the time series data in an array.                                                                                                                                                                    |
| 2   | __name__    | string    | Specify a metric name for the time series data. Specification is mandatory.                                                                                                                                                 |
| 3   | Label Name  | string    | Specify a label name for the time series data.                                                                                                                                                                              |
| 4   | Label Value | string    | Specify label values for temporal data                                                                                                                                                                                      |
| 5   | samples     | Array     | Specify the time series data as an array.                                                                                                                                                                                   |
| 6   | Time        | Number    | Specifies the time of the performance data (the number of milliseconds elapsed since January 1, 1970 00:00:00 (UNIX epoch) in UTC time). You cannot specify a time (negative value) before 0:00:00 a.m. on January 1, 1970. |
| 7   | Value       | Number    | Specify values for the performance data.                                                                                                                                                                                    |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                  |
|-------------|-------------|--------------------------------------------------------------|
| 200         | --          | API processing succeeded.                                    |
| 500         | KAJY62001-E | The Trend Data Management Service returned an error.         |
|             | KAJY62000-E | Communication with the Trend Data Management Service failed. |
|             | KAJY62004-E | Failed to get port number for Trend Data Management Service. |

## Examples

The following is an example of using this API using the OSS curl command.

```
>curl -i --header "Content-Type: application/json" --request POST --data
@c:\\work\\trenddata.json "http://localhost:20703/im/api/v1/trendData/write"
```

trenddata.json

```
{
  "labels":{"__name__":"foo","job":"hoge"},
  "samples":[
    [1617436800000,100]
  ]
}
```

Example of response:

```
HTTP/1.1 200
Vary: Origin
Vary: Access-Control-Request-Method
Vary: Access-Control-Request-Headers
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block
Cache-Control: no-cache, no-store, max-age=0, must-revalidate
Pragma: no-cache
Expires: 0
Content-Length: 0
Date: Fri, 25 Feb 2022 05:59:58 GMT
```

## 5.11.4 Delete Trend Data

### Description

Deletes trend data stored in Trend data Management Database by Prometheus and Fluentd of the specified host including user-defined Prometheus and your own Fluentd. Restarts trend data management service automatically after the trend data is deleted.

Hosts cannot be deleted if the logged-in JP1 user does not have read/write access privileges. Note that all trend data saved by integrated agent, user-defined Prometheus, and Fluentd of the host for which trend data is to be deleted is deleted if IM management node of the host of the user's own Fluentd has read/write access privileges.

After deletion, the deleted information is not reflected in JP1/IM - Manager (Intelligent Integrated Management Base) tree information. To import the information, generate and import the tree information from integrated operation viewer, or execute `jddcreatetree` command and `jddupdatetree` command (specify the configuration change mode (-c option)).

### Execution permissions

- JP1\_Console\_Admin

### API version

v1

### Format

#### Request line

```
POST im/api/v1/trendData/delete HTTP/1.1
```

#### Request message body

```
{
  "deletelist": [
    {
      "managerhost": manager-hostname,
      "deleteinfolist": [
        {
          "agenthost": integrated-agent, user-defined-Prometheus, user-defined-Fluentd-hostname
        }, ...
      ], ...
    }
  ]
}
```

#### Response message body

If the status code is 200 and normal termination occurs, no response is returned.

If the status code is 200 and the warning ends, the following response is returned.

```
{
  "errdeletelist": [
    {
      "managerhost": manager-hostname,
      "deleteinfolist": [
        {
          "agenthost": integrated-agent, user-defined-Prometheus, user-defined-Fluentd-hostname
        }, ...
      ], ...
    }
  ],
}
```

```

"errrestartlist":[
  {
    "managerhost": manager-hostname,
    "deleteinfolist": [
      {
        "agenthost": integrated-agent, user-defined-Prometheus, user-defined-Fluentd-hostname
      },...
    ],...
  },...
],
"messageList":[
  {
    "messageId": message-id,
    "message": messaging
  },...
]
}

```

## Parameters

The following parameters are specified for the message body of the request:

| No. | Parameters     | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                           |
|-----|----------------|-----------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | deletelist     | object[]  | No       | Specify the information to be deleted. You can specify up to 200 <sup>#</sup> to be deleted. An empty array cannot be specified.<br><br>Note #<br>You can specify up to 200 elements of all deleteinfo in a deletelist.                                                                                                                                                               |
| 2   | managerhost    | string    | No       | Specifies <sup>#</sup> of manager hostnames managed by Trend data Management Database that stores trend data to be deleted, from 1 to 255. Characters other than control characters can be specified. It is case sensitive.<br><br>Note #<br>Specify the host name of the host specified in No. 4 as the destination manager host.                                                    |
| 3   | deleteinfolist | object[]  | No       | Specifies the information to be deleted for each manager host. You can specify up to 200 <sup>#</sup> to be deleted. An empty array cannot be specified.<br><br>Note #<br>You can specify up to 200 elements of all deleteinfo in a deletelist.                                                                                                                                       |
| 4   | agenthost      | string    | No       | Specify the host name from 1 to 255 bytes for integrated agent, user-defined Prometheus, and user-defined Fluentd. Characters other than control characters can be specified.<br><br>Deletes Trend data Management Database trend data saved by Prometheus and Fluentd specified by this parameter, including user-defined Prometheus and user-defined Fluentd. It is case sensitive. |

## Response

- When the status code is 200

If the manager specified in the request succeeds in all API operations, regardless of the Integration Manager and lower manager, the response will have no message body.

When an error or warning occurs in the processing of lower manager specified in the request, or when a warning occurs in the processing of the Integration Manager, the information shown in the following table is returned to the message body of the response.

| No. | Parameters     |             | Data type | Optional | Description                                                                                                                                                                                                       |
|-----|----------------|-------------|-----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | errdeletelist  |             | object[]  | Yes      | The array to be deleted that could not delete the trend data is set. If there is no failed deletion target, it is omitted.                                                                                        |
| 2   |                | managerhost | string    | No       | Sets the manager hostname <sup>#</sup> that failed to remove trend data.<br><br>Note #<br>The host name of the host set in No. 4 is set as the host name of the destination manager.                              |
| 3   |                | deleteinfo  | string    | No       | Sets an array of information to be deleted for each manager host for which trend data could not be deleted. If there is no failed deletion target, it is omitted.                                                 |
| 4   |                | agenthost   | string    | No       | Sets the hostname of integrated agent, user-defined Prometheus, or user-defined Fluentd for which trend data could not be deleted.                                                                                |
| 5   | errrestartlist |             | object[]  | Yes      | Trend data is deleted successfully, and an array of items to be deleted that failed to restart trend data management service is set. If there is no failed deletion target, it is omitted.                        |
| 6   |                | managerhost | string    | No       | Configures a manager hostname <sup>#</sup> that successfully deletes trend data and fails to restart trend data management service.<br><br>Note #<br>The host destination manager host name set in Item 8 is set. |
| 7   |                | deleteinfo  | string    | No       | Successful deletion of trend data sets an array of data to be deleted for each manager host that fails to restart trend data management service. If there is no failed deletion target, it is omitted.            |
| 8   |                | agenthost   | string    | No       | Successfully deleted trend data and trend data management service reboot fails to set the hostname of integrated agent, user-defined Prometheus, and user-defined Fluentd.                                        |
| 9   | messageList    |             | object[]  | Yes      | An array of message objects is set. If the message does not exist, it is omitted.                                                                                                                                 |
| 10  |                | messageId   | string    | No       | The messaging ID is set.                                                                                                                                                                                          |
| 11  |                | message     | string    | No       | The message body is set. The language used is determined by Accept-Language property specification in HTTP request header.                                                                                        |

- When an error with a status code other than 200 occurs

The response-type exception object described in [5.2.6 Error response message](#) is returned in the message body of the response.

## Status codes

The following table lists the status codes and messages returned in response to requests.

| Status code | Message     | Description                                                                                                                                                                                                                                                                                                                                                              |
|-------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | None        | API operation was successful.                                                                                                                                                                                                                                                                                                                                            |

| 500         | KAJY00007-E | A system error occurred (out of disk, out of memory, etc.).                                                                                                                                                                                                                                                                                                              |

## Return value

None

## Notes

Refer to *Notes on Deleting trend data in 2.7.2(3)(g) Deleting Trend Data Manually (Specify integrated agent, user-defined Prometheus, and user-defined Fluentd host names and Delete)* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## Examples

Request:

```
POST http://immhost01:20703/im/api/v1/trendData/delete
Manager hostname: immhost01

{
  "deletelist": [
    {
      "managerhost": "hostB"
      "deleteinfolist": [
        {
          "agenthost": "hostA"
        }
      ]
    },
    {
      "managerhost": "hostD"
      "deleteinfolist": [
        {
          "agenthost": "hostC"
        }
      ]
    }
  ]
}
```

```

    }
  ]
}
}

```

#### Response (normal):

```

< HTTP/1.1 200 OK
< Content-Type: application/json

```

#### Response (normal):

```

< HTTP/1.1 200 OK
< Content-Type: application/json
{
  "errdeletelist": [
    {
      "managerhost": "hostB",
      "deleteinfolist": [
        {
          "agenthost": "hostA"
        }
      ]
    }
  ],
  "errrestartlist": [
    {
      "managerhost": "hostD",
      "deleteinfolist": [
        {
          "agenthost": "hostC"
        }
      ]
    }
  ],
  "messageList": [
    {
      "messageId": "KAJY62011-W",
      "Message": "A host that cannot delete trend data was specified. (JP1/IM-Manager host name : hostB, deletion target host name : hostA)"
    },
    {
      "messageId": "KAJY62013-W",
      "Message": "An attempt to restart the trend management service after deleting trend data failed. (JP1/IM-Manager host name : hostD, deletion target host name : hostC)"
    }
  ]
}

```

## 5.12 API for information management

This section describes operations for information management.

### 5.12.1 Version information acquisition

#### Description

Gets the JP1/IM product version and supported REST API versions. This API can be invoked without authentication because it is invoked before all the REST APIs including the login API are invoked.

#### Execution permissions

None.

#### API version

None.

#### Formats

Request line

```
GET /application/component/version httpVersion
```

Request header

The common request header.

Note that you do not specify cookies in the request header.

Request message body

None.

Response header

The common response header.

Response message body

```
{
  "productName": "product-name",
  "productVersion": "product-version",
  "apiVersion": ["REST-API-version", "REST-API-version", ...]
}
```

#### Parameters

None.

#### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message | Description                                         |
|-------------|---------|-----------------------------------------------------|
| 200         | --      | The version information was retrieved successfully. |

#### Return values

The following information is returned in the response body if the status code is 200:

| No. | Member name | Data type | Description                                                              |
|-----|-------------|-----------|--------------------------------------------------------------------------|
| 1   | productName | string    | Returns the name of the product whose version information was retrieved. |

| No. | Member name    | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|----------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | productVersion | string    | Returns the version of the product in <i>VV-RR</i> or <i>VV-RR-SS</i> format.<br>For example, the returned value is <i>12-00</i> which omits <i>SS</i> when the version of the product is <i>12-00</i> , and the returned value is <i>12-00-02</i> when the version of the product is <i>12-00-02</i> .                                                                                                                                       |
| 3   | apiVersion     | array     | Returns an array of the supported REST API versions in <i>VV.RR.SS</i> format. <i>VV</i> , <i>RR</i> , and <i>SS</i> are two-digit numbers.<br>For <i>apiVersion</i> in the URI of the REST API request, an array is returned where the value of <i>VV</i> is concatenated with a letter <i>v</i> with the first digit <i>0</i> removed.<br>For example, if the value of <i>VV</i> is <i>01</i> , <i>apiVersion</i> in the URI is <i>v1</i> . |

## Examples

### Request:

```
GET /im/api/version HTTP/1.1
Accept-Language: ja
Content-Type: application/json
Accept: application/json
```

### Response:

```
HTTP/1.1 200 OK
Cache-Control: no-store, no-cache, max-age=0
Pragma: no-cache
Expires: Thu, 01 Jan 1970 00:00:00 GMT
Content-Type: application/json

{
  "productName": "JP1/Integrated Management 3 - Manager",
  "productVersion": "12-00",
  "apiVersion": ["01.00.00"]
}
```

## 5.13 Suggestion API

---

This section describes suggestion API-related operations.

### 5.13.1 Previous execution history acquisition

#### Description

Gets history information that shows when the response actions corresponding to either the specified IM management node or suggestion IDs were previously executed.

#### Execution permissions

- JPl\_Console\_Admin
- JPl\_Console\_Operator
- JPl\_Console\_User

#### API version

v1

#### Format

##### Request line

```
POST /application/component/apiVersion/nodes/suggestions/history httpVersion
```

##### Request message body

```
{
  "sid": tree-SID-of-IM-management-node,
  "suggestionIds": list-of-suggestion-IDs
}
```

##### Response message body

```
{
  "histories": [
    {
      "suggestionId": suggestion-ID,
      "label": display-name-of-suggestion,
      "jplUserName": name-of-JPl-user-executing-response-action,
      "startTime": date-and-time-when-response-action-started,
      "endTime": date-and-time-when-response-action-ended,
      "status": response-action-execution-status
    },
    ...
  ]
}
```

#### Parameters

sid

Specify the tree SID of the IM management node. This parameter cannot be omitted.

suggestionIds

Specify a list of suggestion IDs. You can specify a list of 1 to 1,000 suggestion IDs. If you specify an empty list, the error message KAJY22019-E is output, and the acquisition of the history of the previously executed response actions stops.

When this parameter is omitted, the history of previously executed response actions is acquired for only those suggestion definitions mapped to the specified IM management node that the logged-in user is qualified to view.

When the specified suggestion IDs correspond to either those suggestions definitions that are not mapped to the tree SID of the specified IM management node or those which the logged-in user is not allowed to view, the error message KAJY22021-E is output, and the acquisition of the history of the previously executed response actions stops.

## Status codes

The following table describes the status codes that may be returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                           |
|-------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | None        | Successfully acquired the previous execution history.                                                                                                                                                 |
| 400         | KAJY22019-E | The request of the REST API is invalid.<br>The possible causes are: invalid format of the tree SID of the IM management node, invalid suggestion IDs, invalid number of lists of suggestion IDs, etc. |
|             | KAJY22022-E | The request of the REST API is invalid.<br>There are duplicate suggestion IDs.                                                                                                                        |
|             | KAJY22011-E | Either the specified tree SID does not exist or the logged-in user does not have the permission to view the specified IM management node.                                                             |
|             | KAJY22021-E | The specified suggestion IDs correspond to either those suggestions that are not mapped to the specified IM management node or those which the logged-in user is not allowed to view.                 |
| 403         | KAJY01000-E | The logged-in user does not have the permission to execute the REST API.                                                                                                                              |

When the status code is 200, the following information is returned in the response body:

| No. | Member name  | Data type | Description                                                                                                                                                                                                                                                                                                                                                        |
|-----|--------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | histories    | object[]  | Returns the history of previously executed response actions as an array.<br>When there are no suggestion definitions that are mapped to the tree SID of the specified IM management node, or when the logged-in user is allowed to view none of the suggestion definitions mapped to the tree SID of the specified IM management node, an empty array is returned. |
| 2   | suggestionId | string    | Sets the suggestion ID.                                                                                                                                                                                                                                                                                                                                            |
| 3   | label        | string    | Sets the display name of the suggestion.                                                                                                                                                                                                                                                                                                                           |
| 4   | jp1UserName  | string    | The name of the JP1 user executing the response action.<br>This member is not returned when there is no previous execution history.                                                                                                                                                                                                                                |
| 5   | startTime    | string    | Returns the date and time when the response action was executed, as UTC time in ISO 8601 format. This member is not returned when there is no previous execution history.                                                                                                                                                                                          |
| 6   | endTime      | string    | Returns the date and time when the execution of the response action was completed, as UTC time in ISO 8601 format. When the response action is currently being executed or has failed, an empty string is returned. This member is not returned when there is no previous execution history.                                                                       |

| No. | Member name | Data type | Description                                                                                                                                                                                                                                                                                                           |
|-----|-------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | status      | int       | <p>The execution status of the response action. One of the following values is returned:</p> <ul style="list-style-type: none"> <li>• 0: Currently being executed</li> <li>• 1: Successfully executed</li> <li>• 2: Failed</li> </ul> <p>This member is not returned when there is no previous execution history.</p> |

## Examples

The following example shows how to use this API:

Request:

```
POST http://hostname:20703/im/api/v1/nodes/suggestions/history
{
  "sid": "_ROOT_AllSystems/_HOST_HOSTA/_CATEGORY_managementApplication
s/_OBJECT_JP1IMMGR"
}
```

Response:

```
{
  "histories": [
    {
      "suggestionId": "exec_jim_log",
      "label": "Execution of JP1/IM data collection tool",
      "jplUserName": "jpladmin",
      "startTime": "2020-03-01T00:00:00Z",
      "endTime": "",
      "status": 0
    },
    {
      "suggestionId": "reg_ticket",
      "label": "Registration of ticket to Redmine",
      "jplUserName": "jpladmin",
      "startTime": "2020-03-01T00:00:00Z",
      "endTime": "2020-03-01T00:00:10Z",
      "status": 1
    }
  ]
}
```

## 5.13.2 Response action suggestion

### Description

Compares the suggestion definitions against the suggestion activation criteria and suggests response actions appropriate to the system status, according to the specified IM management node or suggestion ID.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

## API version

v1

## Format

### Request line

```
POST /application/component/apivVersion/nodes/suggestions/suggest httpVersion
```

### Request message body

```
{
  "sid": tree-SID-of-IM-management-node,
  "suggestionIds": list-of-suggestion-IDs
}
```

### Response message body

```
{
  "suggestions": [
    {
      "suggestionId": suggestion-ID,
      "label": display-name-of-suggestion,
      "status": whether-suggestion-activation-criteria-are-satisfied,
      "cases": [
        [
          {
            "description": description-of-criterion,
            "status": status-of-criterion,
            "acquisitionDate": acquisition-date-and-time,
          },
          ...
        ],
        [
          {
            "description": description-of-criterion,
            "status": status-of-criterion,
            "acquisitionDate": acquisition-date-and-time,
          },
          ...
        ],
        ...
      ],
      "action": {
        "type": type-of-response-action,

          "message": message-text
        },
        ...
      ],
      ...
    },
    ...
  ]
}
```

## Parameters

`sid`

Specify the tree SID of an IM management node.

`suggestionIds`

Specify a list of suggestion IDs. You can specify a list of 1 to 1,000 suggestion IDs. If you specify an empty list, the error message KAJY22019-E is output, and the response action suggestion processing stops.

When this parameter is omitted, only those suggestion definitions mapped to the specified IM management node that the logged-in user is allowed to view are compared against the suggestion activation criteria to judge if they satisfy the criteria, and information regarding the suggested response actions that are appropriate to the system status is subsequently acquired.

When the specified suggestion IDs correspond to either those suggestions definitions that are not mapped to the tree SID of the specified IM management node or those which the logged-in user is not allowed to view, the error message KAJY22021-E is output, and the acquisition of response action suggestion information stops.

## Status codes

The following table describes the status codes that may be returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                           |
|-------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | None        | Response actions were successfully suggested.                                                                                                                                                         |
|             | KAJY22026-W | Failed to convert the variables in the suggestion definitions.                                                                                                                                        |
|             | KAJY22027-W | Suggestion information obtained by the conversion of variables in the suggestion definitions is invalid.                                                                                              |
|             | KAJY22028-W | Failed to make a judgment as to whether the suggestion activation criteria are satisfied.                                                                                                             |
|             | KAJY22047-W | Failed to acquire information from the Repeated event list window.                                                                                                                                    |
| 400         | KAJY22020-E | The request of the REST API is invalid.<br>The possible causes are: invalid format of the tree SID of the IM management node, invalid suggestion IDs, invalid number of lists of suggestion IDs, etc. |
|             | KAJY22022-E | The request of the REST API is invalid.<br>There are duplicate suggestion IDs.                                                                                                                        |
|             | KAJY22011-E | Either the specified tree SID does not exist or the logged-in user does not have the permission to view the specified IM management node.                                                             |
|             | KAJY22021-E | The specified suggestion IDs correspond to either those suggestions that are not mapped to the specified IM management node or those which the logged-in user is not allowed to view.                 |
| 403         | KAJY01000-E | The logged-in user does not have the permission to execute the REST API.                                                                                                                              |

When the status code is 200, the following information is returned in the response body:

| N o. | Member name  | Data type | Description                                                                                                                                                                                                                                                                                                                                        |
|------|--------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | suggestions  | object[]  | Returns the acquired suggestion information as an array.<br>When there are no suggestion definitions that are mapped to the tree SID of the specified IM management node, or when the logged-in user is allowed to view none of the suggestion definitions mapped to the tree SID of the specified IM management node, an empty array is returned. |
| 2    | suggestionId | string    | Sets the suggestion ID.                                                                                                                                                                                                                                                                                                                            |
| 3    | label        | string    | Sets the display name of the suggestion.                                                                                                                                                                                                                                                                                                           |
| 4    | status       | int       | Indicates whether the suggestion activation criterion was satisfied. One of the following values are returned:                                                                                                                                                                                                                                     |

| N o. | Member name |                 | Data type  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|-------------|-----------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      |             |                 |            | <ul style="list-style-type: none"> <li>• 0: Criterion satisfied</li> <li>• 1: Criterion not satisfied</li> <li>• 2: Error</li> </ul>                                                                                                                                                                                                                                                                                                                                                                             |
| 5    | cases       |                 | object[][] | Returns double-array data of suggestion criteria objects. The inner array represents a group of AND conditions whereas the outer array represents a group of OR conditions. This member is not returned when the cases member is not specified in the suggestion definitions.                                                                                                                                                                                                                                    |
| 6    |             | description     | string     | Returns the description of the criterion after conversion of the variables.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 7    |             | status          | int        | The status of a criterion. One of the following values is returned: <ul style="list-style-type: none"> <li>• 0: Not judged</li> <li>• 1: Match</li> <li>• 2: Does not match</li> <li>• 3: Error</li> </ul>                                                                                                                                                                                                                                                                                                       |
| 8    |             | acquisitionDate | string     | Returns the date and time when criterion information was acquired, as UTC time in ISO 8601 format.<br><br>When status (status of criterion) is 0 (Not judged) or 3 (Error), an empty string is returned.                                                                                                                                                                                                                                                                                                         |
| 9    | action      |                 | object     | Information regarding a response action is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 10   |             | type            | string     | The type of response action specified in the suggestion definition is returned. For details on the type member, see (2) <a href="#">Response action in Suggestion definition file (imdd_suggestion.conf)</a> in Chapter 2. Definition Files.                                                                                                                                                                                                                                                                     |
| 11   |             | params          | object     | When jump is specified as type of the response action and at the same time relatedEvent is also specified, relatedEvent and members no. 12 to 15 are returned.<br><br>In all the other cases, the parameters of the response action specified in the suggestion definition are returned with their variables converted. For details on the members other than members no. 12 to 15, see (2) <a href="#">Response action in Suggestion definition file (imdd_suggestion.conf)</a> in Chapter 2. Definition Files. |
| 12   |             | suppressId      | int        | The value of the E.JP1_IMSUPPRESS_ID attribute (suppressed event ID) of the JP1 event specified with relatedEvent#                                                                                                                                                                                                                                                                                                                                                                                               |
| 13   |             | eventSevere     | int        | The value of the E.@JP1IM_SEVERE attribute (severe event) of the JP1 event specified with relatedEvent#                                                                                                                                                                                                                                                                                                                                                                                                          |
| 14   |             | suppressName    | string     | The value of the E.JP1_IMSUPPRESS_NAME attribute (repeated event condition name) of the JP1 event specified with relatedEvent#                                                                                                                                                                                                                                                                                                                                                                                   |
| 15   |             | nodeSid         | string     | The tree SID of the IM management node to which the JP1 event specified with relatedEvent# belongs                                                                                                                                                                                                                                                                                                                                                                                                               |
| 16   |             | description     | string     | <ul style="list-style-type: none"> <li>• When status (whether the suggestion activation criterion was satisfied) is 0 (criterion satisfied):<br/>Returns the description of response action with the variables converted.</li> <li>• When status is other than 0:<br/>Returns the description of response action without the variables being converted. If the returned string exceeds 512 characters, it is truncated to 512 characters.</li> </ul>                                                             |
| 17   | messageList |                 | object[]   | Returns the warning message issued during processing that does not prevent the processing from continuing.                                                                                                                                                                                                                                                                                                                                                                                                       |

| N<br>o. | Member name | Data type | Description                                                                                                        |
|---------|-------------|-----------|--------------------------------------------------------------------------------------------------------------------|
|         |             |           | This member is not returned when there is no warning message that does not prevent the processing from continuing. |
| 1<br>8  | messageId   | string    | Returns a message ID.                                                                                              |
| 1<br>9  | message     | string    | Returns message text.                                                                                              |

#

For details on relatedEvent, see information regarding relatedEvent provided in (2)(A)(e) *Response action when type is set to jump* in *Suggestion definition file (imdd\_suggestion.conf)* in Chapter 2. Definition Files.

## Examples

The following example shows how response actions are suggested for the IM management node (tree SID: `_ROOT_AllSystems/_HOST_HOST1/_CATEGORY_platform/_SUBCATEGORY_JP1%2FPPM%20-%20Windows/_OBJECT_JP1PFM-ATA1HOST2`) that belongs to the service provided by the PFM agent that constitutes a management object.

Request:

```
POST http://hostname:20703/im/api/v1/nodes/suggestions/suggest
{
  "sid": "_ROOT_AllSystems/_HOST_HOST1/_CATEGORY_platform/_SUBCATEGORY_JP1%2FPPM%20-%20Windows/_OBJECT_JP1PFM-ATA1HOST2"
}
```

Response:

```
HTTP/1.1 200 OK
Content-Type: application/json
{
  "suggestions": [
    {
      "suggestionId": "check_affected_rootJobnet",
      "label": "Impact on root jobnets affected by host going down",
      "status": 0,
      "cases": [
        {
          "description": "A JP1/AJS - Agent node exists on the same host where the selected node (PFM - Agent) exists",
          "status": 1,
          "acquisitionDate": "2020-03-11T11:00:00Z"
        },
        {
          "description": "A JP1 event indicating that the host stopped has been issued",
          "status": 1,
          "acquisitionDate": "2020-03-11T11:00:01Z"
        },
        {
          "description": "The host of the selected node is down",
          "status": 1,
          "acquisitionDate": "2020-03-11T11:00:02Z"
        }
      ]
    }
  ]
}
```

```

        }
    ],
    "action":
    {
        "type": "jump",
        "params":
        {
            " url": "index?sid=%5FROOT%5FAllSystems%2F%5FHOST%5FHOST1%2F%5FCATEGORY%5FmanagementApplications%2F%5FOBJECT%5FJP1AJSAGT&view=tree&tab=relation&eou=1"
        },
        "description": "Move to the Related node tab displaying the JP1/AJS - Agent node"
    }
}
]
}

```

### 5.13.3 Response action execution

#### Description

Executes the specified response action.

#### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

#### API version

v1

#### Format

##### Request line

```
POST /application/component/apiVersion/nodes/suggestions/action httpVersion
```

##### Request message body

```

{
    "sid": tree-SID,
    "suggestionId": suggestion-ID,
    "action": {
        "type": type-of-response-action,
        "params": parameters-of-response-action,
        "description": description-of-response-action
    }
}

```

##### Response message body

```

{
    "location": URL-of-destination-screen,
}

```

```

    "target": target-attribute-of-html-for-opening-URL-of-destination-screen,
    "suppressId": information-provided-in-the-Repeated-event-list-window-(suppressed-event-ID),
    "eventSevere": information-provided-in-the-Repeated-event-list-window-(severe-event),
    "suppressName": information-provided-in-the-Repeated-event-list-window-(repeated-event-condition-name),
    "nodeSid": information-provided-in-the-Repeated-event-list-window-(tree-SID-of-IM-management-node),
    "message": {
        "messageId": message-ID,
        "message": message-text
    }
}

```

## Parameters

sid

Specify a tree SID.

suggestionId

Specify a suggestion ID. For details on the suggestion ID, see information regarding suggestionId in [Suggestion definition file \(imdd\\_suggestion.conf\)](#) in *Chapter 2. Definition Files*.

action

Specify a response action.

- type: Specify the type of response action. For details on the specifiable types of response actions, see (2) [Response action](#) in [Suggestion definition file \(imdd\\_suggestion.conf\)](#) in *Chapter 2. Definition Files*.
- params: Specify the response action's parameters after conversion of the variables. When the type of response action is jump and at the same time relatedEvent is also specified, the following members must also be specified. For details on each of these members, see [5.13.2 Response action suggestion](#).
  - suppressId
  - eventSevere
  - suppressName
  - nodeSid
- description: Specify the description of the response action after conversion of the variables. You can specify a string not exceeding 512 characters, which must not include control characters. The specification of an empty string is not allowed.

## Status codes

The following table describes the status codes that may be returned as a response to a request:

| Status code | Message     | Description                                                                                                                                                                         |
|-------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | None        | The response action execution REST API was successfully processed.                                                                                                                  |
|             | KAJY22029-W | The response action is currently being executed.                                                                                                                                    |
| 400         | KAJY22031-E | The request of the REST API is invalid.<br>The possible causes are: invalid format of the tree SID of the IM management node, invalid suggestion IDs, invalid response action, etc. |
|             | KAJY22011-E | Either the specified tree SID does not exist or the logged-in user does not have the permission to view the specified IM management node.                                           |

| Status code | Message     | Description                                                                                                                                                                           |
|-------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | KAJY22021-E | The specified suggestion IDs correspond to either those suggestions that are not mapped to the specified IM management node or those which the logged-in user is not allowed to view. |
| 403         | KAJY01000-E | The logged-in user does not have the permission to execute the REST API.                                                                                                              |
| 500         | KAJY22033-E | The upper limit of concurrent executions for the response action is exceeded.                                                                                                         |

When the status code is 200, the following information is returned in the response body:

| No. | Member name  | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|--------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | location     | string    | <p>Returns the URL of the destination screen.</p> <ul style="list-style-type: none"> <li>When the type of response action is <code>jump</code> and at the same time <code>url</code> is also specified:<br/>Returns the URL of the screen to which to jump.</li> <li>In all the other cases:<br/>This member is not returned.</li> </ul> <p>When the response action is being executed, this member is not returned regardless of the type of response action.</p>                                                                                                                                                                     |

| 8   |             | messageId | string    | Returns the message ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 9   |             | message   | string    | Returns the message text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Notes

The maximum number of concurrent executions of this API is 10. When the maximum limit is exceeded, the error message KAJY22033-E is output, and the execution of the response action stops.

## Examples

The following example shows how to execute the response action (suggestion ID: `check_affected_rootJobnet`) that consists of *Move to the Related node tab displaying the JP1/AJS-Agent node* for the IM management node (tree SID: `_ROOT_AllSystems/_HOST_HOST1/_CATEGORY_platform/_SUBCATEGORY_JP1%2FPFM%20-%20Windows/_OBJECT_JP1PFM-ATA1HOST2`) that belongs to the service provided by the PFM agent that constitutes a management object.

Request:

```
POST http://hostname:20703/im/api/v1/nodes/suggestions/action
{
  "sid": "_ROOT_AllSystems/_HOST_HOST1/_CATEGORY_platform/_SUBCATEGORY_JP1%2FPFM%20-%20Windows/_OBJECT_JP1PFM-ATA1HOST2",
  "suggestionId": "check_affected_rootJobnet",
  "action":
  {
    "type": "jump",
    "params":
    {
      "url": "index?sid=%5FROOT%5FAllSystems%2F%5FHOST%5FHOST1%2F%5FCATEGORY%5FmanagementApplications%2F%5FOBJECT%5FJP1AJSAGT&view=tree&tab=relation&eou=1"
    },
    "description": "Move to the Related node tab displaying the JP1/AJS - Agent node"
  }
}
```

```
}  
}
```

**Response:**

```
HTTP/1.1 200 OK  
Content-Type: application/json  
{  
  "location": "index?sid=%5FROOT%5FAllSystems%2F%5FHOST%5FHOST1%2F%5FC  
ATEGORY%5FmanagementApplications%2F%5FOBJECT%5FJP1AJSAGT&view=tree&tab=  
relation&eou=1",  
  "target": ""  
}
```

## 5.14 OpenID authentication API

This section describes the operations related to the OpenID authentication API.

### 5.14.1 Single sign-on mapping definition application

#### Description

Applies the mapping information defined in the single sign-on mapping definition file (`imdd_sso_mapping.properties`) to the Intelligent Integrated Management Base. The set information is immediately applied to the Intelligent Integrated Management Base.

If the definition is applied when the single sign-on mapping definition file has no valid property at all, the KAJY52031-W message is added to the response and the applied single sign-on mapping definitions are cleared.

For details on the single sign-on mapping definition file (`imdd_sso_mapping.properties`), see [Single sign-on mapping definition file \(`imdd\_sso\_mapping.properties`\)](#) in *Chapter 2. Definition Files*.

#### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator

#### API version

v1

#### Format

Request line

```
POST /application/component/apiVersion/updateSsoMap httpVersion
```

Request message body

None

#### Parameters

None

#### Status codes

The following table describes the status codes that may be returned as a response to a request:

| Status code | Return value | Message     | Description                                                                            |
|-------------|--------------|-------------|----------------------------------------------------------------------------------------|
| 200<br>403  | --           | None        | The single sign-on mapping definition application REST API was successfully processed. |
|             |              | KAJY52031-W | The single sign-on mapping definition file has no valid definition.                    |
| 500         | 7            | KAJY01000-E | The logged-in user does not have the permission to execute the REST API.               |
| 500         | 2            | KAJY52022-E | Failed to establish exclusive control for single sign-on mapping definitions.          |
|             | 13           | KAJY52023-E | Failed to apply the single sign-on mapping definition.                                 |
|             | 14           | KAJY52026-E | The single sign-on mapping definition file was not correctly loaded.                   |

#### Return values

The following table describes the return values:

| Return value | Description                           |
|--------------|---------------------------------------|
| 2            | Failed to establish exclusive control |
| 7            | Execution permission error            |
| 13           | Update error                          |
| 14           | Definition file load error            |
| 255          | System error                          |

## Notes

- Concurrent executions of this API are not allowed. Concurrent executions of this API result in an error.
- When an error occurs during the execution of this API, an error message is output to the integrated trace log. An API error response containing the error message is returned to the caller of the API. Using the information provided in the received response, the caller displays the message. When the REST API is called from the `jddupdatessomap` command and an error response is subsequently returned, error information is output to the standard error output. For details on the `jddupdatessomap` command, see [jddupdatessomap](#) in *Chapter 1. Commands*.

## Examples

Request:

```
POST http://hostname:20703/im/api/v1/updateSsoMap HTTP/1.1
Authorization: Bearer xxxx
Accept-Language: ja
Content-Type: application/json
Accept: application/json
```

Response at the end of the warning:

```
{
  "messageList": [
    {
      "messageId": "KAJY52031-W",
      "message": "The Single Sign-on mapping definition file does not contain a valid definition."
    }
  ]
}
```

## 5.15 Distribution API

This section describes distribution API-related operations.

### 5.15.1 Get distribution (File download)

#### Description

Download the distribution (file) specified in the request line.

#### Execution permissions

None<sup>#</sup>

#

You must have execute permissions for the Login API used to log in to the Intelligent Integrated Management Base.

#### API version

None

#### Format

Request line

```
GET /download/Distribution directory name/distribution file name HTTP/1.1
```

Request header

| Header name | Setting value                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Accept      | Do not specify it.<br>Even if specified, "application/zip" is assumed if the file to be downloaded is in zip format, and "application/x-gzip" is assumed if the file to be downloaded is in gz format. |

If message body of the request is in JSON format, the other request headers are the same as Common spec of API. For the request header of Common spec of API, see the explanation of the request header in [5.2.3 Request format](#).

Request message body

None

Response message body

Contents of the distribution's files

#### Parameters

Here are the parameters that you specify for message body of the request:

| No. | Parameters                  | Data type | Description                                                                                                                                                  |
|-----|-----------------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Distribution directory name | string    | Specify the distribution directory as required.<br>If you specify a directory name for a distribution that does not exist, the distribution retrieval fails. |
| 2   | Distribution file name      | string    | Specify the distribution directory as required.<br>If you specify a file name for a distribution that does not exist, the distribution retrieval fails.      |

#### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message   | Description                                                                                                                                                                                                                                                                                                                    |
|-------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | OK        | API processing succeeded.                                                                                                                                                                                                                                                                                                      |
| 403         | Forbidden | Not authenticated,Authentication information is incorrect.                                                                                                                                                                                                                                                                     |
| 404         | Not Found | The specified distribution does not exist, and in a Windows environment, the distribution cannot be accessed.<br>However, in the case of a Windows environment, if you do not have access authority to the distributed file itself, no error will occur, and communication will be closed after a few minutes of non-response. |

If the status code is 200, the contents of the distribution file are returned to the message body of the response.

## Notes

JP1/IM - The following are the requirements for distributions (files) to be stored in Manager (Linux).

### ■Distribution files

- Can be handled as a file
- The file must be compressed (gz format if the distribution destination is Linux environment, zip format if the distribution destination is Windows environment)
- The file name should follow the "zueng031.tifNaming convention for distribution file name and storage destination directory name" below.
- Grant the following permissions to the file:

| Permissions | Owner | Group |
|-------------|-------|-------|
| -r--r--r--  | root  | root  |

- The maximum file size is 300MB.

### ■Directory to create to store distributions

- Create a directory to store the same distribution in the following storage location, and store the distribution in the created directory.

| Storage location            |
|-----------------------------|
| /opt/jplimm/public/download |

- The directory name should follow the "■Naming convention for distribution file name and storage destination directory name" shown below.
- Grant the following permissions to the directory:

| Permissions | Owner | Group |
|-------------|-------|-------|
| drwxr-xr-x  | root  | root  |

### ■Naming convention for distribution file name and storage destination directory name

[Reserved words]

File and directory names that begin with the following strings are reserved words: It is not case sensitive.

- hitachi\_
- jp1\_

The above reserved words are used when distributing files within the scope of functions and services provided by Hitachi products or JP1 products (including JP1/IM - Agent). It cannot be used to distribute other user-specific files.

[Allowed characters]

The following characters are allowed in file and directory names:

- Alphanumeric characters
- - (hyphen)
- . (period)
- \_ (underscore)

#### ■Distribution's file path, including extension

- Must be 235 characters or less

If an environment variable is used for the file path, the file path (including extension) of the distribution after the environment variable is expanded must be 235 characters or less.

#### ■Providers of Distributed Products

- The provider of the distribution (distributed product) shall provide a way to check the version information of the distribution.

You can check the version information of the JP1/IM - Agent in the version file (Version.txt).

For details on where to store version file of JP1/IM - Agent, see (3) *Integrated agent host (Windows)* and (4) *Integrated agent host (Linux)* in Appendix A.4 JP1/IM - Agent in the JP1/Integrated Management 3 - Manager Overview and System Design Guide.

### Examples

Example of request:

```
GET http://hostname:20703/download/im2-agent/xxx.zip
```

## 5.16 API for Execute for Auto/Manual Response Action

This section describes API for Execute for Auto/Manual Response Action-related operations.

### 5.16.1 Obtain execution result of Response Action

#### Description

Gets the execution result of Response Action.

If you set the search criteria to a parameter, you retrieve the execution result of Response Action that match the search criteria.

#### Execution permissions

Following permissions are required:

When only one key "execDetailEventSid" is specified in the filter:

- JP1 permission level: JP1\_Console\_Admin, JP1\_Console\_Operator, JP1\_Console\_User

In other cases:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin, JP1\_Console\_Operator, JP1\_Console\_User

#### API version

v1

#### Format

Request line

```
POST /application/component/apiVersion/responseActions/results httpVersion
```

Request message body

```
{
  "type": "Process content",
  "direction": "ResponseAction execution result acquisition direction",
  "searchType": Search type,
  "count": Acquired number of ResponseAction execution results,
  "since": "Search start position action SID",
  "lastDirection": "Search direction for response action results specified in the previous search process"
  "dbInfo": [
    {
      "beginData": "Search start position action SID",
      "endData": "Search end position action SID",
      "since": "Action SID for the search start position specified in the previous search process"
    }
  ]
  "filter": [ //ResponseAction result search filters
    { "key": "Search key", "ope": "Compare keyword", "val": ["operand 1", ...] },
    ...
  ]
}
```

## Response message body

```
{
  "actionResult":[ //ResponseAction result
    {
      "actionSid":"ResponseAction SID",
      "executionHost":"Destination host Name",
      "actionName":"Action name",
      "executionCommand":"Command",
      "actionStatus":"Action status",
      "targetSid":"Execute target SID",
      "executionDeal":"Execute trigger",
      "executionDetailInfo":"Execute trigger detailed Information",
      "actionType":"Action type",
      "actionAcceptTime":"ResponseAction reception time",
      "actionSendTime":"ResponseAction input time",
      "actionEndTime":"ResponseAction end time",
      "executionResult":["Execute result"],
      "returnValue":"Return value",
      "message":["Message"]
    },
    ...
  ],
  "beginData":"ResponseAction execution result search start position ResponseAction result information",
  "endData":"ResponseAction result information of the search end position of the ResponseAction execution result",
  "dbInfo":"Next search information for the execution result of ResponseAction for distribution DB",
  "messageList":[
    {
      "messageId":"Message ID",
      "message":"Message"
    },
    ...
  ]
}
```

## Parameters

Here are the parameters that you specify for message body of the request:

| Member name | Data type | Optional | Description                                                                                                                                                                                                                                                                                            |
|-------------|-----------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type        | string    | No       | Specifies the execution result of the ResponseAction to retrieve. <ul style="list-style-type: none"> <li>list<br/>Get a list of ResponseAction findings</li> <li>detail<br/>Get ResponseAction result detail info</li> </ul> If a value other than the above is specified, error is returned.          |
| direction   | string    | Yes      | Specify the search direction for ResponseAction execution results. <ul style="list-style-type: none"> <li>past<br/>Search in the past direction</li> <li>future<br/>Search for future directions</li> </ul> The default is "past".<br>If a value other than the above is specified, Error is returned. |

| Member name   |           | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|-----------|-----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| searchType    |           | int       | No       | <p>Specify the search type.</p> <ul style="list-style-type: none"> <li>0: Action SID specification<br/>Specify the target SID for <code>since</code> and 1 for <code>count</code>.</li> <li>1: Latest page</li> <li>2: New page</li> <li>3: Update</li> <li>4: Old page</li> <li>5: Oldest page</li> </ul> <p>If you specify anything other than the above, an error will occur.</p>                                                                                                                                                                                                                                                                                                                                                                              |
| count         |           | int       | Yes      | <p>Specify a range from 1 to 2,000 for the maximum number of results of ResponseAction execution that can be acquired.</p> <p>The default is 100.</p> <p>If a value other than the above is specified, Error is returned.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| since         |           | string    | Yes      | <p>Specify the search start position of the ResponseAction execution result with the corrective action SID.</p> <p>It is specified as a character string of less than 1024 bytes. Otherwise, it is Error.</p> <p>Search for past or future ResponseAction execution results from the specified action SID (The ResponseAction execution result of the specified ResponseAction SID is not included in the search target. However, if count is 1, the specified action SID is searched.)</p> <p>If omitted, the search starts from the beginning or end of the ResponseAction result management database according to the specified direction.</p> <p>For setting method, see ■<i>About setting method for since and direction for retrieval target</i> below.</p> |
| lastDirection |           | string    | Yes      | <p>Specifies the search direction for response action results specified in the previous search process.</p> <p>Specify "past" for the past direction and "future" for the future direction.</p> <p>Required if <code>searchType</code> is 2 or 4.</p> <p>If you specify anything other than the above, an error will occur.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Get detailed Information by <code>ResponseAction</code> SID specification | 0          | Setup <code>ResponseAction</code> SID you want to retrieve.                                                                               | past/future                                                    | Set count to 1 and set "detail" to type.<br><code>lastDirection</code> can be omitted. |

Note: If the above configuration file content is invalid, correct results may not be obtained. If so, execute again from Latest page-first retrieval.

■About `ResponseAction` result search filter

This section explains how to specify parameters.

```
{
  "key": "Search key", "ope": "Comparison keyword", "val": ["operand 1", "operand 2", ...]
}
```

Table 5–14: Combinations of attribute name and compare keywords that can be specified

| Search key<br>(Value to setup)                                | Data type | Comparison keywords                                                                                      | Operand                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------------|-----------|----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ResponseAction</code> SID<br>( <code>actionSid</code> ) | string    | <ul style="list-style-type: none"> <li>Full match (MATCH)</li> <li>Regular expression (REGEX)</li> </ul> | Specify <code>ResponseAction</code> SID.<br>You can specify a maximum of 100 items in the range of 1 to 4096 bytes. Otherwise, it is Error.<br>If you specify a regular expression, you cannot specify more than one. If more than one value is specified, error is set. |
| Destination host name<br>( <code>executionHost</code> )       | string    | <ul style="list-style-type: none"> <li>Full match (MATCH)</li> <li>Regular expression</li> </ul>         | Specifies host name that execute <code>ResponseAction</code> .<br>You can specify a maximum of 100 items in the range of 1 to 4096 bytes. Otherwise, it is error.                                                                                                        |

#### ■About regular expressions

The following regular expressions are used in ResponseAction result finding filter:

- For Windows: Extended regular expressions (XPG4 compliant)
- For Linux: Extended Regular Expressions (POSIX1003.2)

#### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                                                                                                                                                                                    |
|-------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | --                                                                                                                                                                                                                                                                                                                                                             |
| 200         | KAJY63041-W | Some execution results cannot be obtained because communication with the ResponseAction execution control, which is the destination for obtaining ResponseAction execution results, cannot be established.                                                                                                                                                     |
| 200         | KAJY63042-W | An error is returned from the ResponseAction execution control at the ResponseAction execution result acquisition destination, and some execution results cannot be obtained.                                                                                                                                                                                  |
| 400         | KAJY63302-E | <p>REST API parameter was specified incorrectly.</p> <p>&lt;Cause&gt;</p> <ul style="list-style-type: none"> <li>A parameter that cannot be omitted is omitted.</li> <li>You set a value that cannot be set</li> <li>Character limit exceeded</li> <li>The maximum number of items that can be specified is exceeded.</li> <li>Duplicate search key</li> </ul> |
| 400         | KAJY63303-E | JSON formatting of the request message body is invalid.                                                                                                                                                                                                                                                                                                        |
| 403         | KAJY01000-E | You do not have permission to execute REST API.                                                                                                                                                                                                                                                                                                                |
| 500         | KAJY63040-E | Execute destination cannot be obtained from the system configuration information. (There is no management node for the execution request destination host in the system configuration.)                                                                                                                                                                        |
|             |             | Execute destination could not be obtained from the system configuration information. (The integrated agent management base that manages the execution request destination host could not be obtained.)                                                                                                                                                         |
| 500         | KAJY63039-E | The system configuration information is not accessible.                                                                                                                                                                                                                                                                                                        |
| 500         | KAJY63333-E | An unexpected error occurred in REST API processing.                                                                                                                                                                                                                                                                                                           |
| 500         | KAJY00007-E | System error has occurred (out of disk, out of memory, etc.).                                                                                                                                                                                                                                                                                                  |

#### Return values

- When the status code is 200

Returns the data shown in the following tables to message body of the response.

The returned information differs depending on the value specified in the request parameter type.

| Member name |                     | Data type | Value of type |        | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|---------------------|-----------|---------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                     |           | list          | detail |                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|             | actionResult        | object[]  | Y             | Y      | ResponseAction result object. The members returned depend on value specified in type of request parameters.                                                                                                                                                                                                                                                                                                                        |
|             | actionSid           | string    | Y             | Y      | Returns ResponseAction SID.                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | executionHost       | string    | Y             | Y      | Returns the destination host. <ul style="list-style-type: none"> <li>When action type is "cmd"<br/>Host name of the execution destination integrated JP1/IM agent control base</li> <li>When action type is not "cmd"<br/>ResponseAction execute control host name</li> </ul>                                                                                                                                                      |
|             | actionName          | string    | Y             | Y      | Returns action name.                                                                                                                                                                                                                                                                                                                                                                                                               |
|             | executionCommand    | object    | Y             | Y      | Returns the execution command. The object to be returned depends on action type. <ul style="list-style-type: none"> <li>When Action type is "cmd"<br/>See ■ <i>When action type is "cmd"</i> table below.</li> <li>When action type is "restapi"<br/>See ■ <i>When action type is "restapi"</i> table below.</li> <li>When action type is "eventstatus"<br/>See ■ <i>When action type is "eventstatus"</i> table below.</li> </ul> |
|             | actionStatus        | string    | Y             | Y      | Returns status of ResponseAction.                                                                                                                                                                                                                                                                                                                                                                                                  |

### Legend

Y: The information of the applicable member is returned.

N: The information on the applicable member is not returned

■When action type is "cmd"

| Member name | Data type | Description               |
|-------------|-----------|---------------------------|
| cmd         | string    | Returns the command name. |

| Member name | Data type | Description                                      |
|-------------|-----------|--------------------------------------------------|
| envFile     | string    | Returns environment-variable file name and pass. |

■When action type is "restapi"

| Member name | Data type | Description                                                               |
|-------------|-----------|---------------------------------------------------------------------------|
| method      | string    | Returns REST API method.                                                  |
| url         | string    | Returns URL of REST API.                                                  |
| headers     | object    | Returns REST API request headers.                                         |
| body        | string    | Returns REST API request body. Omit the request body if it is not needed. |

■When action type is "eventstatus"

| Member name | Data type | Description                |
|-------------|-----------|----------------------------|
| dealt       | string    | Returns event status.      |
| eventSid    | string    | Returns SID of JP1 events. |

- When the status code is other than 200

In message body of the response, the exception object in the response format described in [5.2.6 Error response message](#) when an Error occurs is returned. However, "returnCode" items are omitted.

When a warning has occurred, a warning information similar to the one with status code 200 is added to the item "extensions" (extended information) and returned to the requestor.

## Examples

### Request:

The following is an example of how to use the API to set search conditions as parameters and acquire information in the ResponseAction result list.

```
POST http://hostname:20703/im/api/v1/responseActions/results HTTP/1.1
content-type: application/json
... (omitted) ...
{
  "type":"list",
  "direction":"past",
  "searchType":1,
  "count":100,
  "filter":[
    {"key":"actionStatus","ope":"MATCH","val":["running","ended"]},
    {"key":"executionHost","ope":"MATCH","val":["HOST185"]},
    {"key":"actionAcceptTime","ope":"TRANGE","val":["2023-10-25T12:00:00+09:00", "2023-10-30T12:00:00+09:00"]}
  ]
}
```

### Response:

```
HTTP/1.1 200
content-type: application/json
... (omitted) ...
{
  "actionResult":[
    {
      "actionSid":"_JP1IMACTID_20f916e2-10d7/_JP1IMMHOST_HOST185/",
      "executionHost": "HOST185",
```

```

        "actionName": "act002",
        "actionType": "eventstatus",
        "executionCommand": {
            "dealt": 3,
            "eventSid": "_JP1IM_HOST185/_JP1IMSEQNO_8/_JP1IMEVBSEQNO_401"
        },
        "actionStatus": "ended",
        "targetSid": "_JP1IM_HOST185/_HOST_HOST185",

        "actionEndTime": "2023-10-27T15:26:50+09:00",
        "returnValue": "0",
        "executionResult": null,
        "message": null
    },
    ... (omitted) ...
],
"beginData": "",
"endData": "_JP1IMACTID_25e566fa-c54a/_JP1IMMHOST_HOST185//",
"dbInfo": [
    {
        "beginData": "_JP1IMACTID_d9947fe1-23a5/_JP1IMMHOST_HOST185//",
        "endData": "_JP1IMACTID_20f916e2-10d7/_JP1IMMHOST_HOST185//",
        "since": ""
    },
    ... (omitted) ...
]
}

```

## 5.16.2 Manual execution of Response Action

### Description

Operate responseAction(manual).

You can execute the following action type "commands":

- Execution of commands
- Execution of REST API
- Updating event status

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/responseActions/manualExec httpV
ersion
```

## Request message body

```
{
  "actionType": "Action type",
  "actionName": "Name of ResponseAction",
  "params": {"Parameters of ResponseAction"}
}
```

### Parameters of ResponseAction

- When action type is set to "Remote command(cmd)"

```
"params": {
  "host": "Execute Host name",
  "cmd": "Command",
  "envFile": " Environment variable file"
}
```

- When action type is "REST API (restapi)"

```
"params": {
  "method": "REST API methods",
  "url": "URL of REST API",
  "headers": "REST API request header",
  "body": "REST API request body"
}
```

- When action type is "Event status updating (eventstatus)"

```
"params": {
  "dealt": "Event status",
  "eventSid": "JP1 Events SID, ..."
}
```

## Response message body

```
{
  "actionSid": " ResponseAction SID",
  "warning": [
    {
      "messageId": "Message ID when a warning occurs",
      "message": "Message when a warning occurs"
    },
    :
  ]
}
```

## Parameters

Here are the parameters that you specify for message body of the request:

| Member name | Data type | Optional | Description                                                                                                                                                                                                                                                |
|-------------|-----------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| actionType  | string    | No       | Specifies type of ResponseAction.<br>One of the following value can be specified: If any other value is specified, error is returned. <ul style="list-style-type: none"><li>cmd<br/>Execute remote command.</li><li>restapi<br/>Execute REST API</li></ul> |

| Member name | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |           |          | <ul style="list-style-type: none"> <li>eventstatus<br/>Execute updating event status of an event.</li> </ul>                                                                                                                                                                                                                                                                              |
| actionName  | string    | Yes      | Specifies name of ResponseAction.<br>The following value can be specified: If any other value is specified, error is returned. <ul style="list-style-type: none"> <li>1 to 50 bytes.</li> <li>All characters except the control character "ASCII code 0x00 to 0x1F,0x7F to 0x9F".</li> </ul>                                                                                              |
| params      | object    | No       | Specifies ResponseAction content.<br>The parameters that you specify depend on type of ResponseAction. <ul style="list-style-type: none"> <li>For cmd<br/>See <i>For remote command (cmd)</i> table below.</li> <li>For restapi<br/>See <i>For REST API(restapi)</i> table below.</li> <li>For eventstatus<br/>See <i>For updating event status (eventstatus)</i> table below.</li> </ul> |

- For remote command (cmd)

| Member name | Data type | Optional | Description                                                                                                                                                                                 |
|-------------|-----------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host        | string    | No       | Specifies execute destination host name. Specify no more than 255 bytes. Otherwise, it is error.                                                                                            |
| cmd         | string    | No       | Execute specifies OS command/parameter to be used. Specify no more than 4096 bytes. Otherwise, it is error.                                                                                 |
| envFile     | string    | Yes      | Specify the absolute path of the file on the execution host that contains the environment variables to be read during command execution. Specify 255 bytes or less. Otherwise, it is error. |

- For REST API(restapi)

| Member name | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-----------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| method      | string    | No       | Specifies the method of REST API to execute. You can specify the following methods: Otherwise, it is error. <ul style="list-style-type: none"> <li>GET</li> <li>HEAD</li> <li>POST</li> <li>PUT</li> <li>PATCH</li> <li>DELETE</li> <li>OPTIONS</li> <li>TRACE</li> </ul>                                                                                                                                                                                                         |
| url         | string    | No       | Specifies URL of REST API to execute. The following value can be specified: Otherwise, it is error. <ul style="list-style-type: none"> <li>Specify 2046 bytes or less.</li> <li>The characters that can be used are one-byte alphanumeric characters and the following symbols according to RFC2396.<br/>";", "/", "?", ":", "@", "&amp;", "=", "+", "\$", "%", "-", "_", ".", "!", "~", "*", "(", ")", "%"</li> <li>Specify "http://" or "https://" at the beginning.</li> </ul> |
| headers     | object    | No       | Specifies the header of REST API to execute. Specify no more than 65,536 bytes. Otherwise, it is error.                                                                                                                                                                                                                                                                                                                                                                           |

| Member name | Data type | Optional | Description                                                                                                                                             |
|-------------|-----------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| body        | string    | Yes      | Specifies the body of REST API to execute. If you do not need a body, omit it. When specifying, specify a value less than 10MB. Otherwise, it is error. |

- For updating event status (eventstatus)

| Member name | Data type | Optional | Description                                                                                                                                                                                                                                    |
|-------------|-----------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dealt       | string    | No       | Specifies value of event status. You can specify value as follows: Otherwise, it is error. <ul style="list-style-type: none"> <li>• 0:Unprocessed</li> <li>• 1:Processed</li> <li>• 2:Processing</li> <li>• 3:Hold</li> </ul>                  |
| eventSid    | string    | No       | Specifies SID of JP1 events. If you specify more than one event SID, concatenate the event SID with ",".<br>You can specify up to 2,000 items. After that, it is error.<br>The number of bytes must be less than 1MB. After that, it is error. |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                                                                                                                                                                         |
|-------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | --                                                                                                                                                                                                                                                                                                                                                  |
| 400         | KAJY64004-E | The content of execute requirement of ResponseAction is invalid.<br><Cause> <ul style="list-style-type: none"> <li>• You are setting a value that cannot be set</li> <li>• Exceeded character limit</li> <li>• A parameter that cannot be omitted is omitted.</li> </ul>                                                                            |
| 400         | KAJY63321-E | JSON formatting of the request message body is invalid.                                                                                                                                                                                                                                                                                             |
| 403         | KAJY01000-E | You do not have execute permission for REST API.                                                                                                                                                                                                                                                                                                    |
| 500         | KAJY63333-E | An unexpected error occurred in REST API processing.                                                                                                                                                                                                                                                                                                |

## ■About Warnings

If the acquisition of information from the non-executable action data table fails, the following message ID is output. The output destination is the warning object of the response when normal, and the warning object of extended information (extensions) when an error occurs.

| Message ID  | Description                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| KAJY63309-W | Cannot communicate with the response action result manage DB.<br><Cause> <ul style="list-style-type: none"> <li>Failed to connect the DB.</li> </ul>     |
| KAJY63310-W | Write error occurred at the response action result manage DB.<br><Cause> <ul style="list-style-type: none"> <li>Failed to operate reading DB.</li> </ul> |

## Return values

- When the status code is 200

If warning information is added to the response returned from the action execution request API, the warning information shown in the following table is added to this REST API response and returned to the request source.

For the information to be returned, see ■*About Warnings* above.

| Member name | Data type | Description                                                                      |
|-------------|-----------|----------------------------------------------------------------------------------|
| actionSid   | string    | Returns a unique ResponseAction SID within ResponseAction results-management DB. |
| warning     | object[]  | Object of the warning message.                                                   |
| messageId   | string    | Returns message ID of the warning that occurred.                                 |
| message     | string    | Returns message of the warning that occurred.                                    |

- When the status code is other than 200

In message body of the response, the exception object in the response format described in [5.2.6 Error response message](#) when an Error occurs is returned. However, "returnCode" items are omitted.

If warning information has been added to the response returned from execute request API of ResponseAction, the warning information shown in the following table is added to the "extensions" (extended information) field of message body of the response during error and returned to the request source.

| Member name | Data type | Description                                                                      |
|-------------|-----------|----------------------------------------------------------------------------------|
| extensions  | object[]  | An object of extended information.<br>Set the warning information that occurred. |
| messageId   | string    | Returns message ID of the warning that occurred.                                 |
| message     | string    | Returns message of the warning that occurred.                                    |

## Examples

### Request:

- The following shows an example of using API when the command is executed.

```
POST http://hostname:20703/im/api/v1/responseActions/manualExec HTTP/1.1
content-type: application/json
... (omitted) ...
{
  "actionType": "cmd",
  "actionName": "act001",
  "params": {
```

```
    "host": "HOST185",  
    "cmd": "dir"  
  }  
}
```

- Here is an example of using API to execute a REST API using JP1 event-information:

```
POST http://hostname:20703/im/api/v1/responseActions/manualExec HTTP/1.1  
content-type: application/json  
... (omitted) ...  
{  
  "actionType": "restapi",  
  "actionName": "act001",  
  "params": {  
    "method": "GET",  
    "url": "http://hostname:20703/im/api/version",  
    "headers": "{}"  
  }  
}
```

- The following is an example of using API to change event status of an event to processed.

```
POST http://hostname:20703/im/api/v1/responseActions/manualExec HTTP/1.1  
content-type: application/json  
... (omitted) ...  
{  
  "actionType": "eventstatus",  
  "actionName": "act001",  
  "params": {  
    "dealt": 1,  
    "eventSid": "_JP1IM_HOST185/_JP1IMSEQNO_8/_JP1IMEVBSEQNO_401"  
  }  
}
```

Response:

```
HTTP/1.1 200 OK  
content-type: application/json  
...  
{  
  "actionSid": "_JP1IMACTID_cb82bd6d-6409/_JP1IMMHOST_HOST185/"  
}
```

## 5.16.3 Convert event-takeover info

### Description

Converts event takeover information.

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator

## API version

v1

## Format

### Request line

```
POST /application/component/apiVersion/responseActions/eventsReplace httpVersion
```

### Request message body

```
{
  "eventSid":"SID of JP1 event",
  "actionType":"Action type",
  "params":{"Parameters of ResponseAction"}
}
```

### Response message body

```
{
  "params":{"Parameters of ResponseAction"},
  "results":{"Convert ResponseAction parameters"}
}
```

#### ■ResponseAction parameters

- When action type" is set to "Remote command (cmd)"

```
"params":{
  "host":"Execute host name",
  "cmd":"Command",
  "envFile":"Environment variable file"
}
```

- When action type" is "REST API(restapi)"

```
"params":{
  "method":"REST API Methods",
  "url":"URL of REST API",
  "headers":"REST API request header",
  "body":"REST API request body"
}
```

- When action type" is "Updating event status of events (eventstatus)"

```
"params":{
  "dealt":Event status,,
  "eventSid":"JP1 Events SID,..."
}
```

- When action type" is "Jumping to the specified URL (jump)"

```
"params":{
  "url":"Destination URL",
  "target":"Target-attributes of HTML"
}
```

## Parameters

Here are the parameters that you specify for message body:

| Member name | Data type | Optional | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| eventSid    | string    | No       | Specifies SID of JP1 events for which you want to retrieve detailed information. For details about JP1 event SID, see <a href="#">7.2.1(1) Event information object</a> . Specify a range of 1~512 bytes. Otherwise, it is error.                                                                                                                                                                                                                                                           |
| actionType  | string    | No       | Specifies type" of ResponseAction.<br>One of the following value can be specified: If any other value is specified, error is returned. <ul style="list-style-type: none"><li>cmd<br/>Execute remote command.</li><li>restapi<br/>Execute REST API</li><li>eventstatus<br/>Execute updating event status of an event.</li><li>jump<br/>Displays/jumps to the specified URL</li></ul>                                                                                                         |
| params      | object    | No       | Specifies ResponseAction content.<br>The parameters that you specify depend on type" of ResponseAction. <ul style="list-style-type: none"><li>For cmd<br/>See <i>For remote command (cmd)</i> table below.</li><li>For restapi<br/>See <i>For REST API (restapi)</i> table below.</li><li>For eventstatus<br/>See <i>Updating event status of events (eventstatus)</i> table below.</li><li>For jump<br/>See <i>When displaying/jumping (jump) the specified URL</i> table below.</li></ul> |

- For remote command (cmd)

| Member name | Data type | Optional | Description                                                                                                                                                                                            |
|-------------|-----------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host        | string    | No       | Specifies Execute destination Host name. Specify a range of 1~255 bytes. Otherwise, it is error.                                                                                                       |
| cmd         | string    | No       | Execute specifies OS command/parameter to be used. Specify a range of 1~4,096 bytes. Otherwise, it is error.                                                                                           |
| envFile     | string    | Yes      | Specifies the absolute file path of file at execute destination, which contains the environment variables to be read during command execution. Specify a range of 1~255 bytes. Otherwise, it is error. |

- For REST API (restapi)

| Member name | Data type | Optional | Description                                                                                                                                               |
|-------------|-----------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| method      | string    | No       | Specifies the method of REST API to execute. Specify 7 bytes or less. Otherwise, it is error.                                                             |
| url         | string    | No       | Specifies URL of REST API to execute. Specify a range of 1~2,046 bytes. Otherwise, it is error.                                                           |
| headers     | object    | No       | Specifies the header of REST API to execute. Specify a range of 1~65,536 bytes. Otherwise, it is error.                                                   |
| body        | string    | Yes      | Specifies the body of REST API to execute. If you do not need a body, omit it. If specified, specify a range of less than 1~10MB. Otherwise, it is error. |

- Updating event status of events (eventstatus)

| Member name | Data type | Optional | Description                                                                                                                                                                                         |
|-------------|-----------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dealt       | int       | No       | Specifies value of event status. Specify with a range of 0~3. Otherwise, it is error.                                                                                                               |
| eventSid    | string    | No       | Specifies SID of JP1 events.<br>To specify multiple event SIDs, consolidated the event SIDs with ",". You can specify up to 2000 records. Specify 1 or more, less than 1MB. Otherwise, it is error. |

- When displaying/jumping (jump) the specified URL

| Member name | Data type | Optional | Description                                                                            |
|-------------|-----------|----------|----------------------------------------------------------------------------------------|
| url         | string    | No       | Specify URL to jump to. Specify a range of 1~2,046 bytes. Otherwise, it is error.      |
| target      | string    | Yes      | Specifies the target attribute. Specify a range of 1~64 bytes. Otherwise, it is error. |

## Status codes

The following shows the status codes that are returned in response. For details about message, see the *JP1/Integrated Management 3 - Manager Messages*.

| Status code | Message     | Description                                                                                                                        |
|-------------|-------------|------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | --                                                                                                                                 |
| 403         | KAJY01000-E | You do not have execute permission for REST API.                                                                                   |
| 400         | KAJY63328-E | REST API parameter was specified incorrectly. The reason is that a parameter that cannot be omitted is omitted.                    |
| 400         | KAJY63329-E | JSON formatting of the request message body is invalid.                                                                            |
| 400         | KAJY63330-E | The maximum number of bytes that can be specified was exceeded as a result of event inheritance information conversion processing. |
| 500         | KAJY63332-E | An error was returned in response from event detail info retrieval API.                                                            |
| 500         | KAJY63333-E | An unexpected error occurred in REST API processing.                                                                               |
| 500         | KAJY00007-E | System error has occurred (out of disk, out of memory, etc.).                                                                      |

## Return values

The following parameters are returned in response.

| Member name | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| params      | object    | Returns the parameters after event inheritance information conversion processing. Return in the same format as the parameterized "params". For details about parameter, see params in the parameter tables.                                                                                                                                                                                                                                     |
| results     | object    | Returns the event takeover data conversion result corresponding to the above "params" parameters. Parameters that are omitted are not returned. Value returned by this parameter is as follows: <ul style="list-style-type: none"> <li>0<br/>Normal termination.</li> <li>1<br/>Upper limit value was exceeded due to variable-transformation.</li> <li>2<br/>The attribute corresponding to the variable does not exist.</li> <li>3</li> </ul> |

| Member name | Data type | Description                                                                                                                                                                          |
|-------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |           | Attribute value of the corresponding property is an empty string. <ul style="list-style-type: none"> <li>4</li> </ul> The encoding specification format for the variable is invalid. |

The response to error is in the format described in [5.2.6 Error response message](#) when an error occurs, but "returnCode" is omitted. Extended information "extensions" assigns the same parameters as the response. However, if error processing occurs before event-takeover information conversion processing, omit this item.

#### ■Extended info (extensions) parameters

```
{
  "timestamp":1539923958358,
  "status":400,
  ...Abbreviated...
  "extensions":{
    "params":{"Parameters of ResponseAction"},
    "results":{"Convert ResponseAction parameters"}
  }
}
```

## Examples

The following shows how to execute a command.

#### Request:

```
POST http://hostname:20703/im/api/v1/responseActions/eventsReplace HTTP
/1.1
content-type: application/json
... (omitted) ...
{
  "eventSid":"_JP1IM_HOST185/_JP1IMSEQNO_8/_JP1IMEVBSEQNO_401",
  "actionType":"cmd",
  "params":{
    "host":"${event:EVHOST:}",
    "cmd":"dir",
    "envFile":"C:\\tmp\\envFile.txt"
  }
}
```

#### Response:

```
HTTP/1.1 200 OK
content-type: application/json
...
{
  "params": {
    "host": "HOST185",
    "cmd": "dir",
    "envFile": "C:\\tmp\\envFile.txt"
  },
  "results": {
    "host": 0,
    "cmd": 0,
    "envFile": 0
  }
}
```

## 5.17 API for definition file manipulation

### 5.17.1 Get definition file list

#### Description

Retrieves a list of defined file for a JP1/IM - Manager or JP1/IM - Agent.

#### Execution permissions

Following permissions are required:

When specify "Manager" at hostCategory

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

When specify "Agent" at hostCategory

- JP1 permission level: JP1\_Console\_Admin

#### API version

v1

#### Format

Request line

```
POST /application/component/apiVersion/fileOperation/getFileList httpVersion
```

Request header

Follow the request header in [5.2.3 Request format](#).

Request message body

Message body of the request can be sent in JSON formats.

```
[
  "hostCategory":"host type",
  "managerHostName":"Defined file list destination agent host-managed destination manger host name",
  "agentHostName":"Defined file list destination agent host name"
]
```

#### Parameters

Here are the parameters that you specify for message body of the request:

| Parameter       | Optional                      | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hostCategory    | No                            | Specify "Manager" or "Agent" as host type. Performs an action on the defined file of the specified host type.                                                                                                                                                                                                                                                                                    |
| managerHostName | See <i>Description</i> column | <ul style="list-style-type: none"><li>• When hostCategory is "Manager"<br/>Ignores the specified item. Assuming that your host is the manager host for JP1/IM, get a list of file defined for the manager host in JP1/IM.</li><li>• When hostCategory is "Agent"<br/>Specifies the manager Host name of JP1/IM that manages agent to which File list is to be acquired, from 1 to 255.</li></ul> |
| agentHostName   | See <i>Description</i> column | <ul style="list-style-type: none"><li>• When hostCategory is "Manager"</li></ul>                                                                                                                                                                                                                                                                                                                 |

| Parameter | Optional | Description                                                                                                                                                                         |
|-----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |          | Ignores the specified item. <ul style="list-style-type: none"> <li>When hostCategory is "Agent"</li> </ul> Specifies agent host of file list destination, in the range of 1 to 255. |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                                                                                                                                                                                                                                                                                                                                |
|             | KAJY02058-W | The format of the user-created definition file list definition file is incorrect.                                                                                                                                                                                                                                                                                                            |

## Return values

- When the status code is 200

Message body of the response returns the auto ResponseAction definition object described in [7.2.4\(1\) Auto Response Action definition Object](#).

For the format of the data, see [3.6.5 \(1\) Function for obtaining list of definition files](#) in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*. The parts that differ from JP1/IM - Agent are shown below.

| Member name         | Description                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------|
| errfilelist:message | Describes message ID and message body of the error message. If it succeeds, omit this item. |

| Member name    | Description                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------------------|
|                | Setup message of KAJY68102-W,KAJY68103-W.                                                                                    |
| message:errmsg | Describes message ID and message body of the error message. If successful, omit message entry. Setup message of KAJY02058-W. |

- When the status code is other than 200

In message body of the response, the exception object in the response format described in [5.2.6 Error response message](#) when an error occurs is returned.

## Examples

### Request:

```
POST http://hostname:20703/im/api/v1/fileOperation/getFileList HTTP/1.1
Authorization:Bearer anAxYWRtaW46TUdGa01tTTJNMLV3TURFNh6STNYeke0T2pJME9qTXpYMTlmWDE5ZlgxOWZYMtImWDE5ZlgycHdNV0ZrYldsU1DQWdJQ0FnSUNBZ01DQWdJQ0FnSUNBZ01DQWdJQ0Fn
Accept-Language: ja
Content-Type: application/json
Content-Length: 1024000
Accept: application/json
{
  "hostCategory": "Agent",
  "managerHostName": "immanager",
  "agentHostName": "imagent"
}
```

### Response:

```
HTTP/1.1 200 OK
Content-Type:application/json
... (omitted) ...

{
  "filelist":[
    {
      "filename": "jpc_alertmanager.yml",
      "filepath": "C:\\Program Files\\Hitachi\\jplima\\conf",
      "filecategoryID": "jpl_imagent",
      "filecategoryName": "jpl_imagent",
      "updatetime": "2023-07-21T10:23+09:00",
      "updateaction": "jplima\\addon_management\\alertmanager\\addon_jpc_service_reload.bat"
    }, ...
  ],
  "errfilelist":[
    {
      "filename": "file_sd_config_test.yml",
      "filepath": "C:\\Program Files\\Hitachi\\jplima\\conf",
    }, ...
  ]
}
```

## 5.17.2 Get definition file

### Description

Retrieves JP1/IM - Manager or JP1/IM - Agent defined File.

### Execution permissions

Following permissions are required:

When specify "Manager" at hostCategory

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

When specify "Agent" at hostCategory

- JP1 permission level: JP1\_Console\_Admin

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/fileOperation/getFile httpVersion
```

Request header

Follow the request header in [5.2.3 Request format](#).

Request message body

Message body of the request can be sent in JSON formats.

```
[
  "filelist":[
    {
      "filename": "File Name",
      "filepath": "absolute path of File"
    }, ...
  ],
  "hostCategory":"host type",
  "managerHostName":"Defined file destination agent host management destination manger host name",
  "agentHostName":"Defined file destination Agent host name"
]
```

### Parameters

Here are the parameters that you specify for message body of the request:

| Parameter       | Optional                      | Description                                                                                                                                                                                                          |
|-----------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename        | No                            | Specifies file name.                                                                                                                                                                                                 |
| filepath        | No                            | Specifies the absolute location of file. If the absolute path including file name in file path exceeds 200 characters, the result is error.                                                                          |
| hostCategory    | No                            | Specify "Manager" or "Agent" as host type. Performs an action on the defined file of the specified host type.                                                                                                        |
| managerHostName | See <i>Description</i> column | <ul style="list-style-type: none"><li>• When hostCategory is "Manager"<br/>Ignores the specified item. Assuming that your host is the manager host for JP1/IM, obtain file of the manager host for JP1/IM.</li></ul> |

| Parameter     | Optional                      | Description                                                                                                                                                                                                                             |
|---------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                               | <ul style="list-style-type: none"> <li>When hostCategory is "Agent"<br/>Specifies the manager host name of JP1/IM that manages agent to which file is to be acquired, from 1 to 255.</li> </ul>                                         |
| agentHostName | See <i>Description</i> column | <ul style="list-style-type: none"> <li>When hostCategory is "Manager"<br/>Ignores the specified item.</li> <li>When hostCategory is "Agent"<br/>Define file specifies agent host to retrieve from, in the range of 1 to 255.</li> </ul> |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                                                                                                                                                                                                                                                                                                                                |
| 400         | KAJY68105-E | Request parameter is invalid.                                                                                                                                                                                                                                                                                                                                                                |

|             | KAJY68212-E | Cannot connect to JP1/IM agent base.                                                                                                                                                                                                                                                                                                                                                         |
|             | KAJY68501-E | Unable to connect to the manager's unified agent host management DB.                                                                                                                                                                                                                                                                                                                         |

If the definition file that you want to retrieve does not exist and you can create a compressed definition file (if you try to retrieve more than one file and some files do not exist), you can find file that failed to retrieve in definition file properties file in the compressed zip file.

## Response

If the status code is 200, the file data of the definition file compressed in zip format is returned to the response body. As a response header, setup the following:

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| Content-Type:application/zip<br>Content-Disposition: attachment; filename="File name of definition file compressed in zip format" |
|-----------------------------------------------------------------------------------------------------------------------------------|

The other response headers are the same as API's common spec. For the response header of common spec of API, see [5.2.5\(2\) Response header](#).

## Return values

- When the status code is 200  
In message body of the response, the file data of the definition file compressed in zip format is returned.
- When the status code is other than 200  
In message body of the response, the exception object in the response format described in [5.2.6 Error response message](#) when an error occurs is returned.

## Examples

### Request:

```
POST http://hostname:20703/im/api/v1/fileOperation/getFile HTTP/1.1
Authorization:Bearer anAxYWRtaW46TUdGa01tTTJNMlV3TURFNh6STNYekE0T2pJME
9qTXpYMTlmWDE5ZlgxOWZYMtImWDE5ZlgxHdNV0ZrYldsdUlDQWdJQ0FnSUNBZ0lDQWdJQ
0FnSUNBZ0lDQWdJQ0Fn
Accept-Language: ja
Content-Type: application/json
Content-Length: 1024000
Accept: application/zip
{
  "filelist":[
    {
      "filename": "jpc_imagent.json",
      "filepath": "C:\\Program Files\\Hitachi\\jplima\\conf",
    }, ...
  ],
  "hostCategory":"Agent",
  "managerHostName":"immanager",
  "agentHostName":"imagent"
}
```

### Response:

```
HTTP/1.1 200 OK
Content-Type:application/zip
Content-Disposition: attachment; filename="C:\\Program Files\\Hitachi\\jp1
ima\\tmp\\upload\\imagenthost_UUID.zip"
... (omitted) ...
```

## 5.17.3 Delete definition file

### Description

Delete JP1/IM - Manager or JP1/IM - Agent definition file.

### Execution permissions

Following permissions are required:

When specify "Manager" at hostCategory

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

When specify "Agent" at hostCategory

- JP1 permission level: JP1\_Console\_Admin

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/fileOperation/deleteFile httpVer
sion
```

## Request header

Follow the request header in [5.2.3 Request format](#).

## Request message body

Message body of the request can be sent in JSON formats.

```
[
  "filelist": [
    {
      "filename": "File Name",
      "filepath": "absolute path of File",
      "updateaction": "Manipulation for defining import"
    }, ...
  ],
  "hostCategory": "host type",
  "managerHostName": "Definition file delete destination agent host management destination manger host name",
  "agentHostName": "Definition file delete destination Agent host name"
]
```

## Parameters

Here are the parameters that you specify for message body of the request:

| Parameter       | Optional                      | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename        | No                            | Specifies File.                                                                                                                                                                                                                                                                                                                                                                                             |
| filepath        | No                            | Specifies the absolute location of file. If the absolute path including file name in file path exceeds 200 characters, the result is error.                                                                                                                                                                                                                                                                 |
| updateaction    | Yes                           | Specifies a value from 1 to 4096 bytes that should be executed when file is updated.                                                                                                                                                                                                                                                                                                                        |
| hostCategory    | No                            | Specify "Manager" or "Agent" as host type. Performs an action on the defined file of the specified host type.                                                                                                                                                                                                                                                                                               |
| managerHostName | See <i>Description</i> column | <ul style="list-style-type: none"><li>When hostCategory is "Manager"<br/>Ignores the specified item. Delete file of the manager host in JP1/IM, assuming that the local host is the manager host in JP1/IM.</li><li>When hostCategory is "Agent"<br/>Specify a value from 1 to 255 bytes for the JP1/IM manager host name that manages the agent from which the definition file is to be deleted.</li></ul> |
| agentHostName   | See <i>Description</i> column | <ul style="list-style-type: none"><li>When hostCategory is "Manager"<br/>Ignores the specified item.</li><li>When hostCategory is "Agent"<br/>Specify the agent host name of the definition file deletion destination with 1 to 255 bytes.</li></ul>                                                                                                                                                        |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                            |
|-------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                                                                          |
|             | KAJY68126-W | JP1/IM agent control base encountered a warning.                                                                                       |
| 400         | KAJY68107-E | Request parameter is invalid.                                                                                                          |
|             | KAJY68205-E | <ul style="list-style-type: none"><li>Integrated agent host name specified in the request does not exist in JP1/IM - Manager</li></ul> |

| Status code | Message     | Description                                                                                                                                                                                                                                                                                  |

|             | KAJY68212-E | Cannot connect to JP1/IM agent base.                                                                                                                                                                                                                                                         |
|             | KAJY68501-E | Unable to connect to the manager's unified agent host management DB.                                                                                                                                                                                                                         |

## Response

If the status code is 200, the following is returned to the response body in JSON format:

```
{
  "filelist":[
    {
      "filename": "File name",
      "filepath": "absolute path of File",
      "result": "Result of file deletion",
      "message": "Message"
    }, ...
  ]
}
```

| Member name      | Description                                                                                                                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename         | Describes file name.                                                                                                                                                                                                                |
| filepath         | Describes the absolute path where file will be placed.                                                                                                                                                                              |
| result           | Describes the outcome of file deletion.<br>See <a href="#">Table 5-15</a> for the character strings to be described.                                                                                                                |
| filelist:message | Provides the error message ID and its body if the action for file deletion fails. If it succeeds, omit this item.<br>If result is recovery fail, the error message in the table indicates message when the import operation failed. |

Table 5–15: Contents of the result

| Delete for file | Operations for importing definition | Recovery process | Content of result |
|-----------------|-------------------------------------|------------------|-------------------|
| Y               | Y                                   | --               | success           |
| N               | --                                  | --               | delete fail       |
| Y               | N                                   | Y                | action fail       |
| Y               | N                                   | N                | recovery fail     |

## Legend

Y: Succeeded, N: Failed, --: No processing

## Return values

- When the status code is 200

None

- When the status code is other than 200

In message body of the response, the exception object in the response format described in [5.2.6 Error response message](#) when an error occurs is returned.

If JP1/IM - Manager is version 13-10 or later and JP1/IM - Agent of Agent host to which definition files are to be deleted is version 13-10 or later, and all definition files fail to be deleted, set the following information in extensions (extended information):

| Item     | Description                                                                           |
|----------|---------------------------------------------------------------------------------------|
| filelist | JSON format shown in the response body of the explanation item "Response" in this API |

## Examples

### Request:

```
POST http://hostname:20703/im/api/v1/fileOperation/deleteFile HTTP/1.1
Authorization:Bearer anAxYWRtaW46TUdGa01tTTJNMLV3TURFNh6STNYekE0T2pJME
9qTXpYMTlmWDE5ZlgxOWZYMtImWDE5ZlgycHdNV0ZrYldsUldQWdJQ0FnSUNBZ0lDQWdJQ
0FnSUNBZ0lDQWdJQ0Fn
Accept-Language: ja
Content-Type: application/json
Content-Length: 1024000
Accept: application/json
{
  "filelist":[
    {
      "filename": "user_file_sd_config_test.yml",
      "filepath": "C:\\\\Program Files\\\\Hitachi\\\\jplima\\\\conf\\\\user",
      "updateaction": "jplima\\\\addon_management\\\\alertmanager\\\\addon_jp
c_service_reload.bat"
    }, ...
  ],
  "hostCategory": "Agent",
  "managerHostName": "immanager",
  "agentHostName": "imagent"
}
```

### Response:

```
HTTP/1.1 200 OK
Content-Type:application/json
... (omitted) ...

{
  "filelist":[
    {
      "filename": "user_file_sd_config_test.yml",
      "filepath": "C:\\\\Program Files\\\\Hitachi\\\\jplima\\\\conf\\\\user",
      "result": "delete fail",
      "message": "KAJY68126-W A warning occurred in the integrated agen
t control platform. (detailed-information : KNBC20015-W Failed to delet
e a definition file. (details = target file does not exist. filename=C:
\\\\Program Files\\\\Hitachi\\\\jplima\\\\conf\\\\user\\\\user_file_sd_config_test.
yml))"
```

```
    }, ...  
  ]  
}
```

## Notes

- After deletion of the definition File, the service might be restart because of import of the definition information.
- If the service startup fails after deletion of file, the system performs a recovery operation. However, if the recovery operation fails, status might be the one in which the service was stopped.
- In a clustered configuration, a deletion of the defined file might cause a failover. Also, you cannot start the service at the failover destination, and the failover might fail. Depending on the load condition, restart and recovery process of the service may take a long time. In the case of a cluster configuration, the cluster software may judge it to be abnormal and cause a failover. For this reason, file's deletion should be performed during system-maintenance hours.

## 5.17.4 Updated definition file

### Description

Update JP1/IM - Manager or JP1/IM - Agent definition file.

### Execution permissions

Following permissions are required:

When specify "Manager" at hostCategory

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

When specify "Agent" at hostCategory

- JP1 permission level: JP1\_Console\_Admin

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/fileOperation/updateFile httpVersion
```

Request header

```
Authorization:BeareranAxYWRtaW46TUdGa01tTTJNMlV3TURFNFh6STNYeke0T2pJME9qTXpYMTlmWDE5ZlgxOWZYMtImWDE5ZlgycHdNV0ZrYldsU1DQWdJQ0FnSUNBZ01DQWdJQ0FnSUNBZ01DQWdJQ0Fn  
Accept-Language: ja
```

Follow the request header in [5.2.3 Request format](#).However, Content-Type has the following format:

```
Content-Type: multipart/form-data; boundary=-----5a6a576p44OV44Kh44Kk44Or5pu05paw  
Content-Length: 1024000  
Accept: application/json
```

## Request message body

```

## Parameters

Here are the parameters that you specify for message body of the request:

| Parameter       | Optional                      | Description                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename        | No                            | Specifies the absolute path to file named after zip has been compressed. File number must be between 1 and 200 bytes.<br>Does not check the file size limit and checks the request body size limit.                                                                                                                                                                                                    |
| hostCategory    | No                            | Specify "Manager" or "Agent" as host type. Performs an action on the defined file of the specified host type.                                                                                                                                                                                                                                                                                          |
| managerHostName | See <i>Description</i> column | <ul style="list-style-type: none"><li>When hostCategory is "Manager"<br/>Ignores the specified item. Assuming that your host is the manager host for JP1/IM, refresh file of the manager host in JP1/IM.</li><li>When hostCategory is "Agent"<br/>Specify a value from 1 to 255 bytes for the JP1/IM manager host name that manages the agent to which the definition file is to be updated.</li></ul> |
| agentHostName   | See <i>Description</i> column | <ul style="list-style-type: none"><li>When hostCategory is "Manager"<br/>Ignores the specified item.</li><li>When hostCategory is "Agent"<br/>Specify the agent host name of the definition file update destination with 1 to 255 bytes.</li></ul>                                                                                                                                                     |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                      |
|-------------|-------------|--------------------------------------------------|
| 200         | --          | API operation was successful.                    |
|             | KAJY68126-W | JP1/IM agent control base encountered a warning. |
| 400         | KAJY68111-E | Request parameter is invalid.                    |

| Status code | Message     | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | KAJY68205-E | <ul style="list-style-type: none"> <li>Integrated agent host name specified in the request does not exist in JP1/IM - Manager</li> <li>Logged in as does not have read/manipulate permissions for integrated agent specified in the request</li> <li>The information of the integration agent or the host specified in the request is not in the unified agent host management DB</li> </ul> |
| 403         | KAJY01000-E | The privilege of the user used for authentication is insufficient.                                                                                                                                                                                                                                                                                                                           |
| 500         | KAJY68104-E | JP1/IM agent control base encountered an error.                                                                                                                                                                                                                                                                                                                                              |
|             | KAJY00009-E | Request body limit exceeded.                                                                                                                                                                                                                                                                                                                                                                 |
|             | KAJY00007-E | System error has occurred (out of disk, out of memory, etc.).                                                                                                                                                                                                                                                                                                                                |
|             | KAJY68203-E | Cannot connect to Intelligent Integrated Management Base.                                                                                                                                                                                                                                                                                                                                    |

|             | KAJY68501-E | Unable to connect to the manager's unified agent host management DB.                                                                                                                                                                                                                                                                                                                         |

## Response

If the status code is 200, the following is returned to the response body in JSON format:

```
{
  "filelist":[
    {
      "filename": "File name",
      "filepath": "File's absolute path",
      "result": "Updating file result",
      "message": "Message"
    }, ...
  ]
}
```

| Member name      | Description                                                                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename         | Describes file name.                                                                                                                                                                                                        |
| filepath         | Describes the absolute path where file will be placed.                                                                                                                                                                      |
| result           | Describes the outcome of file updating.<br>See <a href="#">Table 5-16</a> for the strings to be described.                                                                                                                  |
| filelist:message | Provides the error message ID and its body if file refresh attempt fails. If it succeeds, omit this item.<br>If result is recovery fail, the error message in the table indicates message when the import operation failed. |

**Table 5–16: Contents of the result**

| Overriding File | Operations for importing definition | Recovery process | Content of result |
|-----------------|-------------------------------------|------------------|-------------------|
| Y               | Y                                   | --               | success           |
| N               | --                                  | --               | update fail       |
| Y               | N                                   | Y                | action fail       |
| Y               | N                                   | N                | recovery fail     |

## Legend

Y: Succeeded, N: Failed, --: No processing

## Return values

- When the status code is 200

None

- When the status code is other than 200

In message body of the response, the exception object in the response format described in [5.2.6 Error response message](#) when an error occurs is returned.

If JP1/IM - Manager is version 13-10 or later and JP1/IM - Agent of Agent hostto which the definition file is updated is version 13-10 or later, and all definition files fail to be updated, set the following information in extensions (extended information):

| Item     | Description                                                                           |
|----------|---------------------------------------------------------------------------------------|
| filelist | JSON format shown in the response body of the explanation item "Response" in this API |

## Examples

### Request:

```
POST http://hostname:20703/im/api/v1/fileOperation/updateFile HTTP/1.1

  Content-Disposition: form-data; name="managerHostname"

  "immanager"
  -----5a6a576p44OV44Kh44Kk44Or5pu05paw
  Content-Disposition: form-data; name="agentHostname"

  "imagent"
  -----5a6a576p44OV44Kh44Kk44Or5pu05paw
  Content-Disposition: form-data; name="file"; filename="/C:/Users/xxxxx/Desktop/sample.zip"
  Content-Type: multipart/form-data; boundary=-----5a6a576p44OV44Kh44Kk44Or5pu05paw
  zip data
  -----5a6a576p44OV44Kh44Kk44Or5pu05paw--
]
```

### Response:

```
HTTP/1.1 200 OK
Content-Type:application/json
... (omitted) ...

{
  "filelist":[
    {
      "filename": "user_file_sd_config_test2.yml",
      "filepath": "C:\\Program Files\\Hitachi\\jplima\\conf\\user",
```

```

    "result": "update fail",
    "message": "KAJY68126-W A warning occurred in the integrated agent control platform. (detailed-information : KNBC20020-W Failed to update a definition file. (details = specified file not included in user-definition file list file. filename=C:\\Program Files\\Hitachi\\jplima\\conf\\user\\user_file_sd_config_test2.yml))"
  }, ...
]
}

```

## Notes

- Prior to updating file definition, make sure that the definition file format, character code, etc. are correct manually. If file is invalid, updating might fail. If updating of the defined file fails, an JP1 event is sent. Check the details of JP1 event that occurred and take appropriate action.
- Some services are automatically restarted when file is updated. The monitoring operation may be temporarily stopped by restart of the service. Also, in a clustered configuration, a setup<sup>#</sup> in outage detection times for the monitored services in the cluster software might cause a failover. Therefore, you should refresh file during system-maintenance hours.

#

The estimate of the stop detection time depends on the machine specification and the load condition. However, since the service is restarted for each update of one definition file, consider that it is about one minute for each definition file.

For example, if you are updating 10 files at the same time, set setup for the cluster software shutdown detection period to 10 minutes.

If you cannot increase the detection time, do not use the definition file manipulation feature and login the host. Then, refresh the direct definition file.

## 5.18 API for Integrated agent Administration

### 5.18.1 Retrieve integrated agent info

#### Description

This API is used to obtain integrated agent data.

If an office or relay manager exists under the control of Integrated manager, integrated agent under the control of the office or relay manager is also acquired.

If JP1 user you login has read permission, get agent info.

#### Execution permissions

JP1\_Console\_Admin

#### API version

v1

#### Format

Request line

```
POST /im/api/v1/agents httpVersion
```

Request message body

None

Response message body

```
{
  "agents": [
    Integrated agent info Object, ...
  ],
  "messageList": [
    {
      "messageId": Message ID,
      "message": Message
    }, ...
  ]
}
```

#### Parameters

None

#### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                                                                    |
|-------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                                                                                                                                                                                  |
| 403         | KAJY01000-E | The permission of the user used for authentication is insufficient.                                                                                                                                                                            |
| 200         | KAJY68500-W | Unable to connect to the manager's integrated agent host administration DB.<br>If you are unable to connect to integrated agent host administration DB of more than one administration manager, specify host name with a concatenation of ",". |

| Status code | Message     | Description                                                                                                                                                                                                                                 |
|-------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | KAJY68204-W | Cannot connect to the manager's Intelligent Integrated Management Base.<br>If you are unable to connect to Intelligent Integrated Management Base of more than one manager, specify host name with a concatenation of ',' for each manager. |
| 200         | KAJY68210-W | Intelligent Integrated Management Base operation encountered an error.                                                                                                                                                                      |
| 500         | KAJY68501-E | Unable to connect to the manager's unified agent host management DB.                                                                                                                                                                        |

## Return values

The following table describes the return value.

| Parameter name               | Data type | Optional | Description                                                                                                                |
|------------------------------|-----------|----------|----------------------------------------------------------------------------------------------------------------------------|
| agents                       | object[]  | No       | Specifies an array of integrated agent info objects.<br>If integrated agent does not exist, specify an empty array.        |
| Integrated agent info object | object    | Yes      | See <a href="#">7.2.5(1) Integrated agent Info object</a> .                                                                |
| messageList                  | object    | Yes      | Message specifies an array of objects.<br>If Message does not exist, it is omitted.                                        |
| messageId                    | string    | No       | Specify message ID.                                                                                                        |
| message                      | string    | No       | Specify message body.<br>The language used is determined by Accept-Language property specification in HTTP request header. |

## Examples

### Request:

```
POST http://hostname:20703/im/api/v1/agents
```

### Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json
{
  "agents": [
    {
      "agentid": "RENEMzNENDg5RkQyNEM2OT",
      "hostname": "agenthostA",
      "os": "windows",
      "installpath": "\\Program Files\\Hitachi\\jplima",
      "imversion": "130000",
      "managerhost": "managerhostA",
      "registeredtime": "2020-03-01T00:00:00Z",
      "addons": [
        {
          "addonName": "Windows metric collector(Window
s exporter)",
          "enables": true
        }
      ]
    }
  ]
}
```

```
]
}
```

## 5.18.2 Delete integrated agent info

### Description

This API is used to delete the specified integrated agent. Deletes Prometheus of the specified integrated agent host and the trend data that Fluentd has stored in Trend data Management Database. Restarts trend data management service automatically after the trend data is deleted. It also deletes integrated agent host that deleted the trend data.

You can Delete a integrated agent for which JP1 user who Login has read/write access. When trend data is deleted, all trend data saved by integrated agent, user-defined Prometheus, and Fluentd of the host that is specified as the target of trend data deletion is deleted if IM management node of the user's own Fluentd host has read/write access privileges.

After deletion, the deleted information is not reflected in JP1/IM - Manager (Intelligent Integrated Management Base) tree information. To import the information, generate and import the tree information from integrated operation viewer, or execute `jddcreatetree` command and `jddupdatetree` command (specify the configuration change mode (-c option)).

### Execution permissions

JP1\_Console\_Admin

### API version

v1

### Format

#### Request line

```
POST /im/api/v1/agents/delete httpVersion
```

#### Request message body

```
{
  "agents": [
    {
      "agenthost": integrated agent host name,
      "managerhost": manager host name
    }, ...
  ]
}
```

#### Response message body

If successful, there is no response.

If the warning ends, the following response is returned.

```
{
  "errhostlist":[
    {
      "agenthost": integrated-agent-hostname,
      "managerhost": manager-hostname
    }, ...
  ]
  "errdeletelist":[
    {
      "Agenthost": integrated-agent-hostname,
      "managerhost": manager-hostname,

```

```

        }, ...
    ],
    "errrestartlist": [
        {
            "Agenthost": integrated-agent-hostname,
            "managerhost": manager-hostname,
        }, ...
    ],
    "messageList": [
        {
            "messageId": Message ID,
            "message": Message
        }, ...
    ]
}

```

## Parameters

Here are the parameters that you specify for message body:

| Parameter name | Data type | Optional | Description                                                                                                                |
|----------------|-----------|----------|----------------------------------------------------------------------------------------------------------------------------|
| agents         | object[]  | No       | Specifies the Unified Agent to delete. You can specify up to 200 integrated agents.<br>An empty array cannot be specified. |
| agenthost      | string    | No       | Specify host name of integrated agent, from 1 to 255.                                                                      |
| managerhost    | string    | No       | Specifies the manager host name from 1 to 255 bytes.                                                                       |

## Response

| Parameter name | Data type | Optional | Description                                                                                                                                                                                           |
|----------------|-----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| errhostlist    | object[]  | Yes      | The array is populated with the Unified Agents that failed to be deleted. If there are no failed hosts, it is omitted.<br>Includes hosts that have failed to delete trend data <i>errdeletelist</i> . |
| agenthost      | string    | No       | Hostname of the integrated agent is set.                                                                                                                                                              |
| managerhost    | string    | No       | Manager hostname is set.                                                                                                                                                                              |
| errdeletelist  | object[]  | Yes      | Sets an array of integrated agent for which trend data could not be deleted. Omitted if there are no failed hosts.                                                                                    |
| agenthost      | string    | No       | Sets the hostname of integrated agent for which trend data could not be deleted.                                                                                                                      |
| managerhost    | string    | No       | Sets the manager host name for which trend data could not be deleted.                                                                                                                                 |
| errrestartlist | object[]  | Yes      | Sets the array of integrated agent that successfully deleted trend data and failed to restart trend data management service. Omitted if no host failed to reboot.                                     |
| agenthost      | string    | No       | Sets the hostname of integrated agent on which trend data was deleted successfully and trend data management service failed to reboot.                                                                |
| managerhost    | string    | No       | Configures a manager hostname that successfully deletes trend data and fails to restart trend data management service.                                                                                |

| Parameter name |           | Data type | Optional | Description                                                                                                                                |
|----------------|-----------|-----------|----------|--------------------------------------------------------------------------------------------------------------------------------------------|
| messageList    |           | object[]  | Yes      | The array of message objects is populated. If the message does not exist, it is omitted.                                                   |
|                | messageId | string    | No       | The message ID is set.                                                                                                                     |
|                | message   | string    | No       | The body of the message is set. The language used depends on what is specified in the Accept-Language property of the HTTP request header. |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 400         | KAJY68201-E | API request is invalid.<br>The process is turned stopped when one incorrect request is found.                                                                                                                                                                                                                                                                                                                                                                     |

| 200         | KAJY68204-W | Cannot connect to Intelligent Integrated Management Base of the manager for the specified integrated agent.                                                                                                                                                                                                                                                                                                                                                       |
| 200         | KAJY68210-W | Intelligent Integrated Management Base operation encountered an error.                                                                                                                                                                                                                                                                                                                                                                                            |
| 200         | KAJY62012-W | Failed to remove trend data in Trend data Management Database on the specified manager host.                                                                                                                                                                                                                                                                                                                                                                      |
| 200         | KAJY62013-W | Failed to restart trend data management service on the specified manager host.                                                                                                                                                                                                                                                                                                                                                                                    |
| 200         | KAJY62014-W | Unable to connect to integrated agent Administration DB of the manager host specified in Delete trend data operation.                                                                                                                                                                                                                                                                                                                                             |
| 200         | KAJY62015-W | Because Delete trend data or integrated agent info deletion was performed consecutively, trend data deletion was performed consecutively for Trend data Management Database on the same host.                                                                                                                                                                                                                                                                     |
| 200         | KAJY62011-W | <ul style="list-style-type: none"> <li>The logged-in user does not have integrated agent, user-defined Prometheus, or user-defined Fluentd host browse and manipulate permissions specified in the request.</li> <li>The specified manager host is lower manager and has not been added to lower manager in the [lower manager List] window.</li> <li>The specified agent host does not exist in the configuration managed by the Integration Manager.</li> </ul> |
| 200         | KAJY68214-W | Failed to remove event-forwarding relay source information.                                                                                                                                                                                                                                                                                                                                                                                                       |
| 500         | KAJY00007-E | A system error occurred (out of disk, out of memory, etc.).                                                                                                                                                                                                                                                                                                                                                                                                       |

## Return values

None

## Notes

See *Notes on Deleting Trend Data* in 2.7.2(3)(h) *Deleting Trend Data Manually (Delete from Managed Object)* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

## Examples

### Request:

```
POST http://hostname:20703/im/api/v1/agents/delete
{
  "agents": [
    {
      "agenthost": "hostA",
      "managerhost": "hostB"
    }
  ]
}
```

### Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json
```

## 5.18.3 Retrieve Secret List

### Description

Get a list of secrets that JP1/IM agent control base manages.

### Execution permissions

JP1\_Console\_Admin

### API version

v1

### Format

#### Request line

```
POST /application/component/apiVersion/agents/secrets httpVersion
```

#### Request header

Follow the request header in [5.2.3 Request format](#).

#### Request message body

Message body of the request can be sent in JSON formats.

```
[
  "agenthost": "integrated agent host name",
  "managerhost": "Manager host name"
]
```

#### Response message body

Returns a list of secrets. In this case, value of obfuscated and secret is an empty string.

```

{
  "secrets": [
    {
      "key": "Key1",
      "obfuscated": "",
      "secret": ""
    },
    {
      "key": "Key2",
      "obfuscated": "",
      "secret": ""
    },
    {
      "key": "Key3",
      "obfuscated": "",
      "secret": ""
    }
  ]
}

```

## Parameters

Here are the parameters that you specify for message body:

| Parameter name | Data type | Optional | Description                                             |
|----------------|-----------|----------|---------------------------------------------------------|
| agenthost      | string    | No       | Specify integrated agent host in the range of 1 to 255. |
| managerhost    | string    | No       | Specify the manager host name in the range of 1 to 255. |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                                                                                                                                  |
|-------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                                                                                                                                                                                                                                                |
| 400         | KAJY68209-E | Request parameter is invalid.                                                                                                                                                                                                                                                                                |
| 400         | KAJY68205-E | <ul style="list-style-type: none"> <li>Integrated agent host name specified in the request or the configuration managed by the manager host name does not exist in JP1/IM - Manager</li> <li>Logged in as does not have read/manipulate permissions for integrated agent specified in the request</li> </ul> |
| 403         | KAJY01000-E | The permission of the user used for authentication is insufficient.                                                                                                                                                                                                                                          |

## Error message output

API response, including the content of the error message, is returned to the caller when an Execute of Error occurs. The caller displays Message at the caller, using the information of the received response.

## Return values

None

## Examples

### Request:

```
POST http://immhost01:20703/im/api/v1/agents/secrets
```

Manager host name: immhost01

```
{
  "agenthost": "hostA",
  "managerhost": "hostB"
}
```

### Response:

Omitted

## 5.18.4 Add, update, delete the secrets

### Description

Execute add, update, and delete of the secret that you want JP1/IM agent control base to manage.

You can register up to 1,000 secrets.

### Execution permissions

JP1\_Console\_Admin

### API version

v1

### Format

#### Request line

```
POST /application/component/apiVersion/agents/secrets/change httpVersion
```

#### Request header

Follow the request header in [5.2.3 Request format](#).

#### Request message body

Message body of the request can be sent in JSON formats.

- Execute only add or refresh (Delete is not executed)

Write the secret that you want to add in "add".

```
[
  "agenthost": "integrated agent host name",
  "managerhost": "Manager host name",
  "add": {
    "secrets": [
      {
        "key": "key1",
        "secret": "Plaintext secret 1"
      },
      {

```

```

        "key": "key2",
        "secret": "Plaintext secret 2"
    },
    {
        "key": "key3",
        "secret": "Plaintext secret 3"
    }
]
}

```

- If you want to execute only deletion (do not execute a add or refresh)

Write the secret that you want to delete in "delete".

```

[
  "agenthost":"integrated agent host name",
  "managerhost":"Manager host name",
  "delete": {
    "secrets": [
      {
        "key": "key1",
      },
      {
        "key": "key2",
      },
      {
        "key": "key3",
      }
    ]
  }
]
}

```

- To execute add or updating and deletion

Write add or the secret you want to renew on add and put the secret you want to delete on "delete".

If you specify the same key for "add" and "delete", "add" applies.

```

[
  "agenthost":"integrated agent host name",
  "managerhost":"Manager host name",
  "add": {
    "secrets": [
      {
        "key": "key1",
        "secret": "Plaintext secret 1"
      },
      {
        "key": "key2",
        "secret": "Plaintext secret 2"
      },
      {
        "key": "key3",
        "secret": "Plaintext secret 3"
      }
    ]
  },
  "delete": {
    "secrets": [

```

```

    {
      "key": "key1",
    },
    {
      "key": "key2",
    },
    {
      "key": "key3",
    }
  ]
}

```

Response message body

None

## Parameters

Here are the parameters that you specify for message body:

| Parameter name | Data type | Optional | Description                                                                                                                                                                                                  |
|----------------|-----------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| agenthost      | string    | No       | Specify integrated agent host in the range of 1 to 255.                                                                                                                                                      |
| managerhost    | string    | No       | Specify the manager Host name in the range of 1 to 255.                                                                                                                                                      |
| add            | object    | Yes      | Specifies the secret to add or refresh. If you do not have a secret to add or refresh, omit it.                                                                                                              |
| secrets        | object[]  | No       | Specifies the secret to add or refresh.                                                                                                                                                                      |
| key            | string    | No       | Specify the secret key for the key name.<br>The number of characters that can be specified is 1 to 1024, and the number of characters that can be specified is ASCII (0x20 to 0x7e). Otherwise, it is error. |
| secret         | string    | No       | Specify a secret.<br>The number of characters that can be specified is 1 to 1024, and the number of characters that can be specified is ASCII (0x20 to 0x7e). Otherwise, it is error.                        |
| delete         | object    | Yes      | Specifies the secret to delete. If there is no secret to delete, omit it.                                                                                                                                    |
| secrets        | object[]  | No       | Specifies the secret to delete.                                                                                                                                                                              |
| key            | string    | No       | Specify the secret key for the key name.<br>The number of characters that can be specified is 1 to 1024, and the number of characters that can be specified is ASCII (0x20 to 0x7e). Otherwise, it is error. |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                                                                                                                                                                                                                                                  |
|-------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                                                                                                                                                                                                                                                |
| 400         | KAJY68209-E | Request parameter is invalid.                                                                                                                                                                                                                                                                                |
| 400         | KAJY68205-E | <ul style="list-style-type: none"> <li>Integrated agent host name specified in the request or the configuration managed by the manager host name does not exist in JP1/IM - Manager</li> <li>Logged in as does not have read/manipulate permissions for integrated agent specified in the request</li> </ul> |
| 403         | KAJY01000-E | The permissions of the user used for authentication is insufficient.                                                                                                                                                                                                                                         |
| 500         | KAJY00007-E | System error has occurred (out of disk, out of memory, etc.).                                                                                                                                                                                                                                                |

| Status code | Message     | Description                                                                                                 |
|-------------|-------------|-------------------------------------------------------------------------------------------------------------|
| 500         | KAJY02039-E | An internal error occurred (such as an invalid API parameter or environmental error).                       |
| 500         | KAJY68203-E | Cannot connect to Intelligent Integrated Management Base of the manager for the specified integrated agent. |

| 500         | KAJY68211-E | Intelligent Integrated Management Base operation encountered an error.                                      |
| 500         | KAJY68212-E | Cannot connect to JP1/IM agent base.                                                                        |
| 500         | KAJY68501-E | Unable to connect to the manager's unified agent host management DB.                                        |

### Error message output

API response, including the content of the error message, is returned to the caller when an Execute of Error occurs. The caller displays Message at the caller, using the information of the received response.

### Return values

None

### Examples

#### Request:

```
POST http://immhost01:20703/im/api/v1/agents/secrets/change
```

Manager host name: immhost01

```
{
  "agenthost": "hostA",
  "managerhost": "hostB",
  "add": {
    "secrets": [
      {
        "key": "key1",
        "secret": "secret1"
      },
      {
        "key": "key2",
        "secret": "secret2"
      }
    ]
  }
}
```

#### Response:

Omitted

## 5.19 API for Lower manager Info Management

### 5.19.1 Retrieve lower manager info list

#### Description

Retrieves a list of base manager or relay manager under Integrated manager.

#### Execution permissions

Following permissions are required:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

#### API version

v1

#### Format

Request line

```
GET /application/component/apiVersion/subManagers httpVersion
```

Request header

Follow the request header in [5.2.3 Request format](#).

Request message body

None

Response message body

```
{
  "subManagers": [
    hostname, ...
  ]
}
```

#### Parameters

None

#### Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                         |
|-------------|-------------|---------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                       |
| 403         | KAJY01000-E | The permission of the user used for authentication is insufficient. |
| 500         | KAJY68501-E | Unable to connect to Unified Agent Host Management DB.              |

#### Return values

The following information is returned in the response body, if the status code is 200:

| Member name | Data type | Optional | Description                                                                                                                               |
|-------------|-----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------|
| subManagers | string[]  | No       | Specifies an array of host name for lower manager. Specify host name within the range of 1 to 255.<br>An empty array cannot be specified. |

## Error message output

API response, including the content of the error message, is returned to the caller when an execution error occurs. The caller displays message at the caller, using the information of the received response.

## Examples

### Request:

```
GET http://immhost01:20703/im/api/v1/subManagers
```

Manager host name: immhost01

### Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json
{
  "subManagers": ["hostA"]
}
```

## 5.19.2 Add lower manager info

### Description

Register the information of the base manager or relay subordinate manager under the integration manager.

If information for registered subordinate managers, if specified, is updated with that information.

Only hosts registered as subordinate hosts of Integration Manager in IM Configuration Management can be specified.

### Execution permissions

Following permissions are required:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

### API version

v1

### Format

Request line

```
POST /application/component/apiVersion/subManagers/createInfo httpVersion
```

Request header

Follow the request header in [5.2.3 Request format](#).

Request message body

Message body of the request can be sent in JSON formats.

```
{
  "hostname": Host-name,
  "initialsecret": Initial-secret
}
```

Response message body

None

## Parameters

Here are the parameters that you specify for message body:

| Parameter name | Data type | Optional | Description                                                                                                                                                         |
|----------------|-----------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hostname       | string    | No       | Specify host name of lower manager in the range of 1 to 255.                                                                                                        |
| initialsecret  | string    | No       | Specify initial secret.<br>The number of characters that can be specified is 1 to 1024, and the number of characters that can be specified is ASCII (0x20 to 0x7e). |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                             |
|-------------|-------------|-----------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                           |
| 400         | KAJY68012-E | API request is invalid.<br>The process is turned stopped when one bad request is found. |
| 403         | KAJY01000-E | The privilege of the user used for authentication is insufficient.                      |
| 500         | KAJY68501-E | Unable to connect to Unified Agent Host Management DB in Unified Agent Manager.         |
| 500         | KAJY68203-E | Cannot connect to Intelligent Integrated Management Base on lower manager.              |
| 500         | KAJY68017-E | Add of lower manager data has failed.                                                   |

## Return values

There is no response body.

## Examples

### Request:

```
POST http://immhost01:20703/im/api/v1/subManagers/createInfo
{
  "hostname": "hostA",
  "initialsecret": "XXXXXXXXXXXX"
}
```

Manager host name: immhost01

### Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json
```

## 5.19.3 Delete lower manager info

### Description

Delete base manager or relay manager under Integrated manager.

### Execution permissions

Following permissions are required:

- JP1 resource group: \*
- JP1 permission level: JP1\_Console\_Admin

## API version

v1

## Format

### Request line

```
POST /application/component/apiVersion/subManagers/deleteInfo httpVersion
```

### Request header

Follow the request header in [5.2.3 Request format](#).

### Request message body

Message body of the request can be sent in JSON formats.

```
{
  "subManagers": [
    hostname, ...
  ]
}
```

### Response message body

If successful, there is no response.

If the warning ends, the following response is returned.

```
{
  "errhostlist": [
    hostname, ...
  ],
  "messageList": [
    {
      "messageId": Message ID,
      "message": Message
    }, ...
  ]
}
```

## Parameters

Here are the parameters that you specify for message body of the request:

| Parameter name | Data type | Optional | Description                                                                                                                               |
|----------------|-----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------|
| subManagers    | string[]  | No       | Specifies an array of host name for lower manager. Specify host name within the range of 1 to 255.<br>An empty array cannot be specified. |

## Status codes

The following table describes the status codes that are returned as a response to the request:

| Status code | Message     | Description                                                                             |
|-------------|-------------|-----------------------------------------------------------------------------------------|
| 200         | --          | API operation was successful.                                                           |
| 400         | KAJY68013-E | API request is invalid.<br>The process is turned stopped when one bad request is found. |
| 403         | KAJY01000-E | The permission of the user used for authentication is insufficient.                     |

| Status code | Message     | Description                                                                                                                                                                                                                                                                   |
|-------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 500         | KAJY68501-E | Unable to connect to Integration agent host management DB for Integration Manager.                                                                                                                                                                                            |
| 200         | KAJY68500-W | Cannot connect to integrated agent host administration DB of lower manager. If you are unable to connect to integrated agent administration DB of more than one administration manager, host name contains a concatenation of the administration managers host name with ",". |
| 200         | KAJY68204-W | Cannot connect to Intelligent Integrated Management Base on lower manager. If you are unable to connect to Intelligent Integrated Management Base of more than one manager, host name will contain a concatenation of the respective manager host name with ",".              |
| 200         | KAJY68016-W | Lower manager data does not exist.                                                                                                                                                                                                                                            |
| 200         | KAJY68018-W | Delete of lower manager data has failed.                                                                                                                                                                                                                                      |

## Return values

| Parameter name | Data type | Optional | Description                                                                                                                                |
|----------------|-----------|----------|--------------------------------------------------------------------------------------------------------------------------------------------|
| errhostlist    | string[]  | Yes      | Sets an array of host names of subordinate managers that failed to delete. If there are no failed hosts, it is omitted.                    |
| messageList    | object    | Yes      | The array of message objects is populated. If the message does not exist, it is omitted.                                                   |
| messageId      | string    | No       | The message ID is set.                                                                                                                     |
| message        | string    | No       | The body of the message is set. The language used depends on what is specified in the Accept-Language property of the HTTP request header. |

## Examples

### Request:

```
POST http://immhost01:20703/im/api/v1/subManagers/deleteInfo
{
  "subManagers": ["hostA"]
}
```

Manager host name: immhost01

### Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json
{
  "errhostlist": [
    "hostA"
  ],
  "messageList": [
    {
      "messageId": "KAJY68500-W",
      "message": "The Intelligent Integrated Management Base DB cannot be connected to.(JP1/IM-Manager hostname : hostA)"
    }
  ]
}
```

## 5.20 Dashboard definition API

### 5.20.1 Get dashboard definition

#### Description

An API that retrieves dashboard definitions for a dashboard ID specified in the URL in JSON format.

If dashboard get/list collection/deletion function for administrators is enabled, you can also retrieve dashboard definitions owned by other JP1 users when JP1 resource group is "\*" and you are logged in as a JP1 user with JP1\_Console\_Admin privileges.

If you are logged in as a JP1 user with other privileges, or if the dashboard get/list collection/deletion function for administrators is disabled, retrieve the shared or personal dashboard definitions owned by JP1 user who ran API, and the shared dashboard definitions owned by other users, in JSON format. You cannot retrieve personal dashboard definitions owned by other JP1 users. You can edit the acquired dashboard.

The following tables show the dashboard definitions that can be retrieved depending on whether dashboard get/list collection/deletion function for administrators is enabled or disabled and the privileges of the JP1 user who logged in.

For more information about dashboard get/list collection/deletion function for administrators, see *3.2.4 Dashboard Import / Export Function and Expanded Delete Function in the JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

For details about the dashboard definition objects that you get in the Get dashboard definition API, see *7.2.6(1) Dashboard Definition Object*.

Table 5–17: Dashboard definitions that can be retrieved based on the privileges of the JP1 user who logged in

| Privileges for JP1 Users                                        | The dashboard get/ list collection/ deletion function for administrators |                                     |
|-----------------------------------------------------------------|--------------------------------------------------------------------------|-------------------------------------|
|                                                                 | Enabled                                                                  | Disabled                            |
| JP1 Resource Group is "*" and has JP1_Console_Admin privileges. | All dashboard definitions                                                | Own or shared dashboard definitions |
| Other than the above                                            | Own or shared dashboard definition                                       | Own dashboard definitions           |

#### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

When dashboard get/list collection/deletion function for administrators is enabled

If JP1 resource group is "\*" and you are logged in as a JP1 user with JP1\_Console\_Admin privileges, you can also retrieve personal dashboard definitions owned by other JP1 users.

#### API versioning

v1

#### Format

Request line

```
GET /application/component/apiVersion/dashboard/uis/Dashboard-ID httpVersion
```

Request header

Follow the request header in [5.2.3 Request format](#).

Request message body

None

Response message body

*Dashboard definition object*

## Parameters

None

## Status code

The following table lists the status codes returned in response to requests.

| Status code | Messages that are output | Description                                                                                                  |
|-------------|--------------------------|--------------------------------------------------------------------------------------------------------------|
| 200         | --                       | API operation was successful.                                                                                |
| 400         | KAJY12006-E              | The corresponding dashboard does not exist. Or you specified a dashboard that does not have read permission. |
| 500         | KAJY12007-E              | Failed to get dashboard.                                                                                     |

## Return value

- When the status code is 200

The response message body returns the dashboard definition object described in [7.2.6\(1\) Dashboard Definition Object](#).

- When the status code is other than 200

The exception object in the response format described in [5.2.6 Error response message](#) is returned in the message body of the response.

## Examples

Request:

```
GET http://immhost01:20703/im/api/v1/dashboard/uis/1
```

Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json

## 5.20.2 Get dashboard definitions list

### Description

An API that gets a list of dashboard definitions.

Gets an array of defined dashboard definitions (dashboard definition objects). There is no upper limit on the number of arrays to get. However, data (panel data) of the dashboard definition object is null.

If the dashboard get/list collection/deletion function for administrators is enabled, get a list including dashboard definitions owned by other JP1 users when JP1 resource group is "\*" and you are logged in as a JP1 user with JP1\_Console\_Admin privileges. If you are logged in as a JP1 user with other permissions, or if the dashboard get/list collection/deletion function for administrators is disabled, get a list of dashboard definitions owned by the logged in JP1 user along with a list of dashboard definitions whose publishing scope is Shared.

The following tables show the dashboard definitions that can be get in the list depending on whether the dashboard get/list collection/deletion function for administrators is enabled or disabled and the privileges of the JP1 user who logged in.

For details about the dashboard get/list collection/deletion function for administrators, see *3.2.4 Dashboard Import / Export Function and Expanded Delete Function* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

**Table 5–18: Dashboard definitions available in the list depending on the permissions of JP1 user logged in**

| Privileges for JP1 Users                                        | The dashboard get/list collection/deletion function for administrators |                                      |
|-----------------------------------------------------------------|------------------------------------------------------------------------|--------------------------------------|
|                                                                 | Enabled                                                                | Disabled                             |
| JP1 Resource Group is "*" and has JP1_Console_Admin privileges. | All dashboard definitions                                              | Own or shared dashboard-definition # |
| Other than the above                                            | Own or shared dashboard-definition #                                   |                                      |

#

Gets a list of dashboard definitions owned by the logged-in JP1 user along with a list of dashboard definitions whose publishing scope is Shared.

### Execution authority

- JP1\_Console\_Admin

- JP1\_Console\_Operator
- JP1\_Console\_User

When the dashboard get/list collection/deletion function for administrators is enabled

If JP1 resource group is "\*" and you are logged in as a JP1 user with JP1\_Console\_Admin operational permissions, you can get it in the list, including dashboard definitions owned by other JP1 users.

## API versioning

v1

## Format

Request line

```
GET /application/component/apiVersion/dashboard/uis httpVersion
```

Request header

Follow the request header in [5.2.3 Request format](#).

Request message body

None

Response message body

*Array of dashboard definition objects*

## Parameters

None

## Status code

The following table lists the status codes returned in response to requests.

| Status code | Messages that are output | Description                   |
|-------------|--------------------------|-------------------------------|
| 200         | --                       | API operation was successful. |
| 500         | KAJY12007-E              | Failed to get dashboard.      |

## Return value

- When the status code is 200  
An array of dashboard definition objects, as described in [7.2.6\(1\) Dashboard Definition Object](#) is returned in the message body of the response.
- When the status code is other than 200  
The exception object in the response format described in [5.2.6 Error response message](#) is returned in the message body of the response.

## Examples

Request:

```
GET http://immhost01:20703/im/api/v1/dashboard/uis
```

Response

```
< HTTP/1.1 200 OK
< Content-Type: application/json
[
  {
    "id": 1,
    "title": "CPU Usage Weekly Report",

## 5.20.3 Add dashboard definition

### Function

This API creates a new dashboard with the dashboard definition object specified in the parameter.

Dashboard definition objects can be get in the Get Dashboard Definition API and the definitions can optionally be edited before specifying them in the parameters. For example, if you are restoring a definition from another host, you might need to modify SID included in the definition.

Id and owner members of the dashboard definition object are not used when specified. The value of ID (the value of id member) is newly numbered in JP1/IM - Manager and the owner (the value of owner member) is JP1 username that performed the additional dashboard-definition API. In addition, the dashboard refresh date and time is the date and time when you performed the Add Dashboard Definition API.

For details about dashboard definition objects, see [7.2.6\(1\) Dashboard Definition Object](#).

### Execution authority

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

### API versioning

v1

### Format

Request line

```
POST /application/component/apiVersion/dashboard/uis httpVersion
```

Request header

Follow the request header in [5.2.3 Request format](#).

Request message body

```
Dashboard definition object
```

## Response message body

*Dashboard definition object*

## Parameters

For details about the dashboard definition object for the message body of a request, see [7.2.6\(1\) Dashboard Definition Object](#).

## Status code

The following table lists the status codes returned in response to requests.

| Status code | Messages that are output | Description                                    |
|-------------|--------------------------|------------------------------------------------|
| 200         | --                       | API operation was successful.                  |
| 400         | KAJY12009-E              | The specified dashboard definition is invalid. |
| 500         | KAJY12010-E              | Failed to add dashboard.                       |

## Return value

- When the status code is 200

For details about the dashboard definition object for the message body of the response, see [7.2.6\(1\) Dashboard Definition Object](#).

- When the status code is other than 200

The exception object in the response format described in [5.2.6 Error response message](#) is returned in the message body of the response.

## Examples

Request:

```
POST http://immhost01:20703/im/api/v1/dashboard/uis
{
  "id": 1,
  "title": "Weekly Report",
  "memo": "{\\"sid\\":\\"_ROOT_AllSystems/_HOST_HISOL8150143/_CATEGORY_o
therApplications/_OBJECT_JP1BASETRAP\\"}",

    "updateTime": 1711870802
}

```

## 5.20.4 Delete dashboard definition

### Function

This API deletes the dashboard definition for the dashboard ID specified in URL.

If the dashboard get/list collection/deletion function for administrators is enabled, you can also remove dashboard definitions owned by other JP1 users when JP1 resource group is "\*" and you are logged in as a JP1 user with JP1\_Console\_Admin privileges. If you are logged in as a JP1 user with other permissions, or if the dashboard get/list collection/deletion function for administrators is disabled, you can only remove dashboard definitions owned by the logged in JP1 user.

The following tables show the dashboard definitions that can be deleted depending on whether the dashboard get/list collection/deletion function for administrators is enabled or disabled and the privileges of the JP1 user who logged in.

For details about the dashboard get/list collection/deletion function for administrators, see *3.2.4 Dashboard Import / Export Function and Expanded Delete Function* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

**Table 5–19: Dashboard definitions that can be deleted depending on the permissions of the logged in JP1 user**

| Privileges for JP1 Users                                        | The dashboard get/list collection/deletion function for administrators |                           |
|-----------------------------------------------------------------|------------------------------------------------------------------------|---------------------------|
|                                                                 | Enabled                                                                | Disabled                  |
| JP1 Resource Group is "*" and has JP1_Console_Admin privileges. | All dashboard definitions                                              | Own dashboard definitions |
| Other than the above                                            | Own dashboard definitions                                              |                           |

### Execution permissions

- JP1\_Console\_Admin
- JP1\_Console\_Operator
- JP1\_Console\_User

When the dashboard get/list collection/deletion function for administrators is enabled

If JP1 resource group is "\*" and you are logged in as a JP1 user with JP1\_Console\_Admin privileges, you can also remove dashboard definitions owned by other JP1 users.

## API versioning

v1

## Format

Request line

```
DELETE /application/component/apiVersion/dashboard/uis/ Dashboard-ID httpVersion
```

Request header

Follow the request header in [5.2.3 Request format](#).

Request message body

None

Response message body

```
Number of deletions
```

## Parameters

None

## Status code

The following table lists the status codes returned in response to requests.

| Status code | Messages that are output | Description                   |
|-------------|--------------------------|-------------------------------|
| 200         | --                       | API operation was successful. |
| 500         | KAJY12011-E              | Failed to delete dashboard.   |

## Return value

- When the status code is 200  
The response message body returns the dashboard definition object described in [7.2.6\(1\) Dashboard Definition Object](#).
- When the status code is other than 200  
The exception object in the response format described in [5.2.6 Error response message](#) is returned in the message body of the response.

## Examples

Request:

```
DELETE http://immhost01:20703/im/api/v1/dashboard/uis/1
```

Response:

```
< HTTP/1.1 200 OK
< Content-Type: application/json
1
```

## 5.21 API for Prometheus server operation

Describes operations related to Prometheus server operation-related API.

### 5.21.1 Reload Prometheus server

#### Description

Reloads Prometheus server definition files (jpc\_prometheus\_server.yml, jpc\_alerting\_rules.yml, file discovery definition files, etc.) and reflects them in the operation of Prometheus server.

Reloading the Prometheus server is faster than restarting the Prometheus server and maintains the state at the time of notification failure.

#### Special Notes on API Operation

- All definition fields are reloaded.
- If you change the threshold of an alert rule and reload, the status of the alert changes to the status corresponding to the changed threshold.
- If you reload an incorrect definition file, all definition entries will not be updated. It is recommended that you use the `promtool check config` command to check the format of the configuration file before reloading.

#### Format

##### Request line

```
POST /-/reload HTTP/1.1
```

##### Request header

| Header Name | Setting Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host        | <p>Specify the information of the host of the Prometheus server to which the API is connected as a header value in the following format.</p> <p>Host name or IP address: Port number</p> <p>":port number" is optional.</p> <ul style="list-style-type: none"><li>• Host name or IP address<br/>Specify the host name or IPv4 address of the Prometheus server.</li><li>• Port number<br/>Specifies the port number to use when connecting to the Prometheus server.</li></ul> <p>This header is optional.</p> |

##### Request message body

None

##### Response message body

If the reload is successful, there is no response.

If the reload fails, a message (the value printed by the Prometheus server) is set indicating the cause of the failure.

#### Status codes

| Status code    | Message       | Description            |
|----------------|---------------|------------------------|
| 200            | OK            | Reloaded successfully. |
| Other than 200 | Other than OK | Reloaded successfully. |

Examples

The following is an example of using this API using the OSS curl command.

On successful reload:

```
>curl --request POST "http://localhost:20713/-/reload"
>
```

On reload failure:

```
>curl --request POST "http://localhost:20713/-/reload"
failed to reload config: couldn't load configuration (--config.file="C:\\j
plpccs\\conf\\jpc_prometheus_server.yml"): parsing YAML file C:\\jplpccs\\
conf\\jpc_prometheus_server.yml: yaml: unmarshal errors:
  line 10: field test not found in type config.plain
>
```

5.21.2 Prometheus server health check

Description

Perform a health check on the Prometheus server.  
The status code always returns 200.

Format

Request line

```
GET /-/healthy HTTP/1.1
```

Request header

| Header Name | Setting Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host        | <p>Specify the information of the host of the Prometheus server to which the API is connected as a header value in the following format.</p> <p>Host name or IP address: Port number</p> <p>":port number" is optional.</p> <ul style="list-style-type: none"><li>• Host name or IP address</li><li>• Port number</li></ul> <p>Specify the host name or IPv4 address of the Prometheus server.</p> <p>Specifies the port number to use when connecting to the Prometheus server.</p> <p>This header is optional.</p> |

Request message body

None

Status codes

Always return 200.

Examples

The following is an example of using this API using the OSS curl command.  
If the Prometheus server is working properly:

```
>curl -I --request GET "http://localhost:20713/-/healthy"
HTTP/1.1 200 OK
```

```
Date: Sat, 07 Aug 2021 01:20:57 GMT
Content-Length: 23
Content-Type: text/plain; charset=utf-8
>
```

**If the Prometheus server is not working properly:**

```
>curl -I --request GET "http://localhost:20713/-/healthy"
curl: (7) Failed to connect to localhost port 20713: Connection refused
>
```

## 5.22 API for Alertmanager operation

Describes operations related to Alertmanager operation-related API.

### 5.22.1 Reload Alertmanager

#### Description

Reload the Alertmanager definition file (jpc\_alertmanager.yml) and reflect it in the operation of Alertmanager. Reloading Alertmanager is faster than restarting Alertmanager and maintains the state it was in when the notification failed.

#### Special Notes on API Operation

- All definition fields are reloaded.
- If you leave an alert in a normal state and change the threshold of the alert rule to become unhealthy, the alert becomes unhealthy.
- If you leave an alert in an abnormal state and change the threshold of the alert rule to become normal, the alert becomes normal.
- If you reload an incorrect definition file, all definition entries will not be updated.

#### Format

##### Request line

```
POST /-/reload HTTP/1.1
```

##### Request header

| Header name | Setup values                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host        | <p>Specifies value of the header for Alertmanager host to which API is connected, in the following format:<br/><i>Host name or IP address : Port number</i><br/>": Port number" is optional.</p> <ul style="list-style-type: none"><li>• <i>Host name or IP address</i><br/>Specifies host name or IPv4 address of Alertmanager.</li><li>• <i>Port number</i><br/>Specifies port number to use when connecting to Alertmanager.</li></ul> <p>This header is not optional.</p> |

##### Request message body

None

##### Response message body

If the reload is successful, there is no response.  
If the reload fails, a message indicating the cause of the failure (the value output by Alertmanager) is set.

#### Status codes

| Status code    | Message       | Description            |
|----------------|---------------|------------------------|
| 200            | OK            | Reloaded successfully. |
| Other than 200 | Other than OK | Reload failed.         |

## Examples

The following is an example of using this API using the OSS curl command.

### On successful reload:

```
>curl --request POST "http://localhost:20714/-/reload"
>
```

### On reload failure:

```
>curl --request POST "http://localhost:20714/-/reload"
failed to reload config: yaml: line 11: could not find expected ':'
>
```

## 5.22.2 Alertmanager health check

### Description

Perform a health check of Alertmanager.

The status code always returns 200.

### Format

Request line

```
GET /-/healthy HTTP/1.1
```

Request header

| Header name | Setup values                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host        | <p>Specifies value of the header for Alertmanager host to which API is connected, in the following format:<br/><i>Host name or IP address : Port number</i></p> <p><i>": Port number"</i> is optional.</p> <ul style="list-style-type: none"><li><i>Host name or IP address</i><br/>Specifies host name or IPv4 address of Alertmanager.</li><li><i>Port number</i><br/>Specifies port number to use when connecting to Alertmanager.</li></ul> <p>This header is not optional.</p> |

Request message body

None

### Status codes

Always return 200.

## Examples

The following is an example of using this API using the OSS curl command.

If Alertmanager is working properly:

```
>curl -I --request GET "http://localhost:20714/-/healthy"
HTTP/1.1 200 OK
Date: Sat, 07 Aug 2021 01:20:57 GMT
Content-Length: 23
Content-Type: text/plain; charset=utf-8
>
```

### If Alertmanager is not working properly:

```
>curl -I --request GET "http://localhost:20714/-/healthy"
curl: (7) Failed to connect to localhost port 20714: Connection refused
>
```

## 5.22.3 Get silence list of Alertmanager

### Description

Gets the list of silences created in Alertmanager in JSON format.

### Format

#### Request line

```
GET /api/v2/silences HTTP/1.1
```

#### Request header

| Header name | Setup values                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host        | <p>Specifies value of the header for Alertmanager host to which API is connected, in the following format:<br/><i>Host name or IP address:Port number</i><br/>":Port number" is optional.</p> <ul style="list-style-type: none"><li>• <i>Host name or IP address</i><br/>Specifies host name or IPv4 address of Alertmanager.</li><li>• <i>Port number</i><br/>Specifies port number to use when connecting to Alertmanager.</li></ul> <p>This header is not optional.</p> |

#### Request message body

None

#### Response message body

```

| startsAt    |         | string    | The date and time when silence is applied is set in the ISO8601 extended format. The date and time will be the time zone specified in the "Create Silence" API.                                                                                                                                                        |
| endsAt      |         | string    | The silence end date and time is set in the ISO8601 extended format. The date and time will be the time zone specified in the "Create Silence" API.                                                                                                                                                                    |
| createdBy   |         | string    | Sets the author name of the silence configuration.                                                                                                                                                                                                                                                                     |
| comment     |         | string    | The comment for the silence settings is set.                                                                                                                                                                                                                                                                           |

## Status codes

| Status code    | Message       | Description                                     |
|----------------|---------------|-------------------------------------------------|
| 200            | OK            | The list of silences was successfully obtained. |
| Other than 200 | Other than OK | Failed to get silence list.                     |

## Examples

The following is an example of using this API using the OSS curl command. In the example below, line breaks and indents have been added for clarity. There are no line breaks or indentation in the actual output. Also, the output order of JSON properties is undefined.

```
>curl --request GET "http://localhost:20714/api/v2/silences"
[
  {
    "id": "787594fd-29a6-495d-921a-d37709f6186e",

## 5.22.4 Silence creation of Alertmanager

### Description

Pass the JSON format silence settings as arguments and create a silence in Alertmanager.

The silence ID returned as a response is an identifier uniquely assigned to the silence setting. Used to run Alertmanager's silence revocation API.

When you set silence, Alertmanager automatically adds the following:

- id
- status
- status.state
- updatedAt
- matchers.isEqual

### Format

Request line

```
POST /api/v2/silences HTTP/1.1
```

## Request header

| Header name  | Setup values                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| createdBy   |  | string    | Specifies the author name.                                                                                                                                                                                                                                                                                                                      |
| comment     |  | string    | Specify a comment.                                                                                                                                                                                                                                                                                                                              |

### Response message body

```
{
  "silenceID": "silenceID"
}
```

### Status codes

| Status code    | Message       | Description                       |
|----------------|---------------|-----------------------------------|
| 200            | OK            | Silence was successfully created. |
| Other than 200 | Other than OK | Silence creation failed.          |

### Examples

The following is an example of using this API using the OSS curl command.

```
> curl --header "Content-Type: application/json" --request POST --data @C:\tmp\silence.json "http://localhost:20714/api/v2/silences"
{"silenceID": "9ae46d02-4db8-4098-a8e4-f9181d66611c"}
>
```

### silence.json:

```
{
  "matchers": [
    {
      "name": "alertname",
      "value": "cpu idel alert",
      "isRegex": false
    }
  ],
  "startsAt": "2021-08-09T19:00:00+09:00",
  "endsAt": "2021-08-09T21:00:00+09:00",
  "createdBy": "api",
  "comment": "test silence"
}
```

## 5.22.5 Silence Revocation of Alertmanager

### Description

Revokes (expires) silences created in Alertmanager.

### Format

Request line

```
DELETE /api/v2/silence/silenceID HTTP/1.1
```

The silence ID can be a value to be retrieved by the "Get Alertmanager Silence List" API or a value returned as a return value of the "Create Alertmanager Silence" API.

Request header

| Header name | Setup values                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host        | <p>Specifies value of the header for Alertmanager host to which API is connected, in the following format:<br/><i>Host name or IP address : Port number</i></p> <p><i>": Port number"</i> is optional.</p> <ul style="list-style-type: none"><li><i>Host name or IP address</i><br/>Specifies host name or IPv4 address of Alertmanager.</li><li><i>Port number</i><br/>Specifies port number to use when connecting to Alertmanager.</li></ul> <p>This header is not optional.</p> |

Request message body

None

Response message body

None

### Status codes

| Status code    | Message       | Description                       |
|----------------|---------------|-----------------------------------|
| 200            | OK            | Silence has successfully expired. |
| Other than 200 | Other than OK | Silence failed to expire.         |

### Examples

The following is an example of using this API using the OSS curl command.

```
>curl --request DELETE "http://localhost:20714/api/v2/silence/b37a053b-6172-46dd-8211-be808cc25e01"

>
```

## 5.22.6 Get silence of Alertmanager

### Description

Gets the specified silence in JSON format.

## Format

### Request line

```
GET /api/v2/silence/silence ID HTTP/1.1
```

For *silence ID*, you can specify value to be returned as the return value of value and silence creation for Alertmanager API to be retrieved in silence list retrieval API of Alertmanager.

### Request header

| Header name | Setup values                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host        | <p>Specifies value of the header for Alertmanager host to which API is connected, in the following format:<br/><i>Host name or IP address : Port number</i><br/>": <i>Port number</i>" is optional.</p> <ul style="list-style-type: none"><li>• <i>Host name or IP address</i><br/>Specifies host name or IPv4 address of Alertmanager.</li><li>• <i>Port number</i><br/>Specifies port number to use when connecting to Alertmanager.</li></ul> <p>This header is not optional.</p> |

### Request message body

None

### Response message body

```
{
  "id": "silence ID",
  "status": {
    "state": "Status"
  },
  "updatedAt": "Update Date/time",
  "comment": "Comment",
  "createdBy": "Author-name",
  "endsAt": "Exit Date/time",
  "matchers": [
    {
      "isRegex": Regex flag,
      "name": "Label name",
      "value": "Value"
    },
    ...
  ],
  "startsAt": "Starting Date/time"
}
```

### Response parameters

See *Response parameters* in the [5.22.3 Get silence list of Alertmanager](#).

### Status codes

| Status code    | Message       | Description                        |
|----------------|---------------|------------------------------------|
| 200            | OK            | Silence was successfully acquired. |
| Other than 200 | Other than OK | Failed to get silence.             |

## Examples

The following is an example of how this API can be used with execution using curl command of OSS. In the use cases below, line breaks and indentation are added for clarity. Newlines and indents are not printed in the actual output. The order of JSON properties is undefined.

```
> curl --request GET "http://localhost:20714/api/v2/silence/00ed3d4d-da1f-4971-81cd-b2687933e602"
{
  "id": "00ed3d4d-da1f-4971-81cd-b2687933e602",
  "status": {
    "state": "active"
  },
  "updatedAt": "2022-08-09T03:35:41.821Z",
  "comment": "cc",
  "createdBy": "aa",
  "endsAt": "2022-08-09T05:35:32.825Z",
  "matchers": [
    {
      "isEqual": true,
      "isRegex": false,
      "name": "env",
      "value": "production"
    }
  ],
  "startsAt": "2022-08-09T03:35:41.821Z"
}
```

## 5.23 API for Blackbox exporter operation

Describes operations related to Blackbox exporter operation-related API.

### 5.23.1 Reload Blackbox exporter

#### Description

Reloads the Blackbox exporter definition file and reflects the operation of the Blackbox exporter.

Reloading the Blackbox exporter is faster than restarting the Blackbox exporter and maintains the state it was in when the notification failed.

#### Format

Request line

```
POST /-/reload HTTP/1.1
```

Request header

| Header name | Setup values                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host        | <p>Specifies value of the header for Alertmanager host to which API is connected, in the following format:<br/><i>Host name or IP address : Port number</i><br/>": <i>Port number</i>" is optional.</p> <ul style="list-style-type: none"><li><i>Host name or IP address</i><br/>Specifies host name or IPv4 address of Alertmanager.</li><li><i>Port number</i><br/>Specifies port number to use when connecting to Alertmanager.</li></ul> <p>This header is not optional.</p> |

Request message body

None

Response message body

If the reload is successful, there is no response.

If the reload fails, a message (the value printed by the Blackbox exporter) is set indicating the cause of the failure.

#### Status codes

| Status code    | Message       | Description            |
|----------------|---------------|------------------------|
| 200            | OK            | Reloaded successfully. |
| Other than 200 | Other than OK | Reload failed.         |

#### Notes

- If you reload an invalid definition file, all contents of the imported definition file will be invalidated.
- The reload will take effect from the next Blackbox exporter API (such as scrape) and will not affect the running API.

#### Examples

The following is an example of using this API using the OSS curl command.

**On successful reload:**

```
>curl --request POST "http://localhost:20715/-/reload"
```

```
>
```

**On reload failure:**

```
# curl -request POST http://localhost:20715/-/reload  
failed to reload config: error parsing config file: yaml: unmarshal error  
s:  
  line 3: field priber not found in type config.plain
```

## 5.24 API for scrape of Exporter used by JP1/IM - Agent

### Description

Scrape each exporter that you want to scrape on the Prometheus server. Scrape is performed at the interval set in item "scrape\_interval" of the Prometheus configuration file (jpc\_prometheus\_server.yml).

Even if a status code other than 200 is returned, it will not be retried.

### Communication method

Communication protocol: HTTP

Port number: Exporter's port number

### Format

Request line

```
GET /metrics# HTTP/1.1
```

The only communication protocol is "HTTP". Specifies the port number of the exporter.

#

The "/metrics" part can be changed in item "metrics\_path" of [scrape\_configs] of the Prometheus configuration file (jpc\_prometheus\_server.yml).

Request header

| Header name                         | Setup values                                                                                                                    |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| host                                | The value of the item "targets" in the Prometheus configuration file (jpc_prometheus_server.yml) is set.                        |
| user-agent                          | Prometheus/2.23.0 is set.                                                                                                       |
| accept                              | "application/openmetrics-text; version=0.0.1,text/plain;version=0.0.4;q=0.5,*/*;q=0.1" is set.                                  |
| accept-encoding                     | "gzip" is set.                                                                                                                  |
| x-prometheus-scrape-timeout-seconds | The value of the item "scrape_timeout" in the Prometheus configuration file (jpc_prometheus_server.yml) is set.                 |
| Other                               | Authentication information is added according to the settings of the Prometheus configuration file (jpc_prometheus_server.yml). |

Request message body

None

Response message body

Returns information in the Prometheus text format shown below.

#### ■Basic Information

| Items                                   | Description                                                                                                 |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Supported Prometheus versions           | 0.40 or later                                                                                               |
| Communication protocol                  | HTTP                                                                                                        |

| Items             | Description                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Supported metrics | <ul style="list-style-type: none"> <li>• Counter</li> <li>• Gauge</li> <li>• Histogram</li> <li>• Summary</li> <li>• Untyped</li> </ul> |

#### ■Text formatting details

- Written line-by-line.
- The newline character at the end of a line must be '\n'.
- Empty lines are ignored.

#### ■Row formatting

- Tokens on a single line can be separated by any number of spaces or tabs.
- Leading and trailing whitespace is ignored.

#### ■Comments,Help Text,Type Information

- Lines beginning with "#" are treated as comments. Lines where the token immediately after the "#" is not "HELP" or type information are ignored.
- If the token immediately following the "#" is "HELP", at least one token with the metric name is required. All remaining tokens are considered descriptive for that metric name.  
Lines of help text can contain any UTF-8 string after the metric name, but backslashes (\) and newline characters (\n) must be escaped, such as "\\\" and "\\n".  
Only one line of help text can be written per metric name.
- If the token immediately following the "#" is type information, describe two or more tokens. The first is the metric name, and the second is counter, gauge, histogram, summary, or untyped, which defines the type of metric.  
Only one line of type information can be described per metric name.  
A row of type information must appear before the first sample for the metric name on that row.  
If no line of type information exists for a metric name, the type of the metric is set to "untyped".

#### ■Sample syntax

```
metric_name [
    "{" label_name "=" `"` label_value `"` { "," label_name "=" `"` lab
el_value `"` } [ "," " ] "]"
] value [ timestamp ]
```

- metric\_name and label\_name have the limitations of normal Prometheus writing.
- label\_value can be any UTF-8 string. Backslashes (\), double quotes ("), and line feeds must be escaped as "\\\"", "\"\"", and "\\n", respectively.
- value is a floating-point number required by Go's ParseFloat() function. In addition to regular numbers, NaN (not numeric), +Inf (positive infinity), and -Inf (negative infinity) values are also valid.
- The timestamp is int64 (milliseconds (excluding leap seconds) since 1970-01-01 00:00:00 UTC). It is displayed as needed in Go's ParseInt() function.

#### ■Grouping and sorting

- All rows for a metric must be provided as a group, along with an optional help text line and a line of type information.

- Each row must be a unique combination of metric name and label.

#### ■ Examples of text formatting

```
# HELP http_requests_total The total number of HTTP requests.
# TYPE http_requests_total counter
http_requests_total{method="post",code="200"} 1027 1395066363000
http_requests_total{method="post",code="400"} 3 1395066363000

# Escaping in label values:
msdos_file_access_time_seconds{path="C:\\DIR\\FILE.TXT",error="Cannot find file:\\n\\FILE.TXT\\"} 1.458255915e9

# Minimalistic line:
metric_without_timestamp_and_labels 12.47

# A weird metric from before the epoch:
something_weird{problem="division by zero"} +Inf -3982045

# A histogram, which has a pretty complex representation in the text format:
# HELP http_request_duration_seconds A histogram of the request duration.
# TYPE http_request_duration_seconds histogram
http_request_duration_seconds_bucket{le="0.05"} 24054
http_request_duration_seconds_bucket{le="0.1"} 33444
http_request_duration_seconds_bucket{le="0.2"} 100392
http_request_duration_seconds_bucket{le="0.5"} 129389
http_request_duration_seconds_bucket{le="1"} 133988
http_request_duration_seconds_bucket{le="+Inf"} 144320
http_request_duration_seconds_sum 53423
http_request_duration_seconds_count 144320

# Finally a summary, which has a complex representation, too:
# HELP rpc_duration_seconds A summary of the RPC duration in seconds.
# TYPE rpc_duration_seconds summary
rpc_duration_seconds{quantile="0.01"} 3102
rpc_duration_seconds{quantile="0.05"} 3272
rpc_duration_seconds{quantile="0.5"} 4773
rpc_duration_seconds{quantile="0.9"} 9001
rpc_duration_seconds{quantile="0.99"} 76656
rpc_duration_seconds_sum 1.7560473e+07
rpc_duration_seconds_count 2693
```

# 6

## Customization of Integrated Operation Viewer Window

This chapter describes the functionality for displaying a window that the user defined in the Related information area when selecting a specific IM management node in the Integrated Operation Viewer window of JP1/IM - Manager (Intelligent Integrated Management Base).

## 6.1 Overview of Integrated Operation Viewer Window customization

This section describes the overview of customization of the Integrated Operation Viewer window and the location of definition files.

### 6.1.1 What is customization of the Integrated Operation Viewer window?

In the customization of the Integrated Operation Viewer window, when the user has selected a certain IM management node, all windows that are based on the information determined in advance can be shown in **Custom UI** tab of the Related information area. In addition, you can also define the titles of the areas.

The following figure shows a window image of the applied customization of the Integrated Operation Viewer window.

Figure 6–1: Example of applying customization to the Integrated Operation Viewer window

### 6.1.2 The storage location

Place the customization definition file of the Integrated Operation Viewer window in the HTML format in the following location by creating a sub folder or subdirectory. Physical hosts and logical hosts are placed in the same location. In a cluster configuration, place the same file in both systems.

Note that subdirectory names starting with `hitachi` cannot be used.

In Windows:

`Manager-path\public\customUI\`

In UNIX:

`/var/opt/jplimm/public/customUI/`

When you uninstall the JP1/IM - Manager, backup files which you located as needed.

### 6.1.3 Notes

The `<iframe>` tag is used in the custom UI tab. Due to this, if you try to display a Web page by using a property such as `window.location.href` when `X-Frame-Options` is specified for that Web page, you will not be able to display the Web page.

In this case, action is needed on the part of the website providing the Web page to allow access from JP1/IM.

Example of a specification

```
X-Frame-Options ALLOW-FROM <URL-of-JP1/IM>
```

## 6.2 Customization definition information of the Integrated Operation Viewer window

This section describes the customization definition information of the Integrated Operation Viewer window.

### 6.2.1 Property information to be defined

The following table shows the property information to be defined.

An item must be specified to a single *custom-UI-Id* in the property. For characters to be specified in *custom-UI-Id*, see [6.2.2 Character string to be specified to custom-UI-Id](#).

Table 6–1: Definition information of the customization of the Integrated Operation Viewer window

| No. | property name                                                   | Required/Optional | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Specification range          |
|-----|-----------------------------------------------------------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| 1   | <code>jp1.imdd.gui.settings.contentView.customUIId.title</code> | Required          | <p>Specify a title to be displayed in the <b>Custom UI</b> tab.<sup>#1</sup></p> <p>If you specify a long string with half-width alphanumeric characters for the title, the WWW browser can truncate the string displayed as a tooltip for the title of the <b>Custom UI</b> tab.</p> <p>When you use half-width space or full-width characters as appropriate in the title string, all the characters are displayed as the tooltip without truncation.</p> | Between 1 and 255 characters |
| 2   | <code>jp1.imdd.gui.settings.contentView.customUIId.url</code>   | Required          | <p>Specify the absolute path from <code>public</code> to the HTML file that you want to display in the user definition window display area.<sup>#1</sup></p> <p>You need to use a forward slash (/) as the path separator character. Even if the path contains a half-width space</p>                                                                                                                                                                       | Between 1 and 255 characters |

| No. | property name                                                     | Required/Optional      | Description                                                                                                                                                                                                                                                          | Specification range                |
|-----|-------------------------------------------------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
|     |                                                                   |                        | <p>character ( ), you do not have to enclose it with double quotation marks (").</p> <p>Note that if a path that does not exist is specified to url, the user definition window display area displays a message in the "Not Found <i>specified-path</i>" format.</p> |                                    |
| 3   | <code>jpl.imdd.gui.settings.contentViews.customUIId.sid</code>    | Required <sup>#2</sup> | <p>Specify the tree SID of the IM management node for displaying the user definition window.</p> <p>You can use a regular expression<sup>#3</sup> to specify it. Note that whether the specified tree SID exists is not checked.</p>                                 | Between 1 and 1,048,576 characters |
| 4   | <code>jpl.imdd.gui.settings.contentViews.customUIId.target</code> | Required <sup>#2</sup> | <p>Specify the SID of an IM management node for displaying the user definition window.</p> <p>You can use a regular expression<sup>#3</sup> to specify it. Note that whether the specified SID exists is not checked.</p>                                            |                                    |

#1:

For specifying 2-byte characters, convert them to Unicode. In this case, the number of characters is counted as the number of those that have already been converted into Unicode characters. You can specify characters other than control characters. Platform-dependent characters cannot be specified.

#2:

For each *custom-UI-Id*, always specify either `sid` or `target`. The specifiable characters depend on the specified tree SID or configuration information SID.

#3:

If you use a regular expression, using many ".\*", which is an expression that matches with all characters, might cause research to take longer. For using ".\*", keep in mind to use ".\*" only where necessary.

## 6.2.2 Character string to be specified to *custom-UI-Id*

You need to specify a character string to *custom-UI-Id* in a property so that the key is unique.

You can specify a character string of half-width alphanumeric characters (case sensitive). Specify 1 to 255 characters. If you define multiple character strings to the same key, the last character that was defined becomes valid. A string starting with `_HITACHI` cannot be specified.

The following shows a specification example:

```
jpl.imdd.gui.settings.contentView.sample.title =Custom+UI
jpl.imdd.gui.settings.contentView.sample.url =./customUI/sample/index.html
jpl.imdd.gui.settings.contentView.sample.target =^(?=. *MYHOST) .*$

jpl.imdd.gui.settings.contentView.sample2.title =Custom+UI
jpl.imdd.gui.settings.contentView.sample2.url =./customUI/sample2/index.html
jpl.imdd.gui.settings.contentView.sample2.sid = _ROOT_AllSystems
```

## 6.2.3 Description example of the Intelligent Integrated Management Base definition file (imdd.properties)

The definition details are written in the Intelligent Integrated Management Base definition file (`imdd.properties`). See [Intelligent Integrated Management Base definition file \(imdd.properties\)](#) in *Chapter 2. Definition Files*.

The following shows the description in the model file (`imdd.properties.model`) of the Intelligent Integrated Management Base definition file (`imdd.properties`):

```
server.port = 20703

#jpl.imdd.gui.settings.contentView.custom UI Id.title =
#jpl.imdd.gui.settings.contentView.custom UI Id.url =
#jpl.imdd.gui.settings.contentView.custom UI Id.sid =
#jpl.imdd.gui.settings.contentView.custom UI Id.target =
```

### (1) When multiple custom UIs are displayed

If you define several different `<custom UI Id>` tags for a single IM management node, the **Custom UI** tabs are displayed as many as the number of defined tags.

Note that the **Custom UI** tabs are displayed in the order of the definition in the Intelligent Integrated Management Base definition file (`imdd.properties`).

The following shows a definition example:

```
jpl.imdd.gui.settings.contentView.System01CustomUI1.title = System01\u30ab\u30b9\u30bf\u30e0UI1
jpl.imdd.gui.settings.contentView.System01CustomUI1.url = ./customUI/sample/customUI1.html
jpl.imdd.gui.settings.contentView.System01CustomUI1.sid = _ROOT_AllSystems/_SYSTEM_SYSTEM01
```

```
jp1.imdd.gui.settings.contentViews.System01CustomUI2.title = System01\u30ab\u30b9\u30bf\u30e0UI2
jp1.imdd.gui.settings.contentViews.System01CustomUI2.url = ./customUI/sample/customUI2.html
jp1.imdd.gui.settings.contentViews.System01CustomUI2.sid = _ROOT_AllSystems/_SYSTEM_SYSTEM01

jp1.imdd.gui.settings.contentViews.System01CustomUI3.title = System01\u30ab\u30b9\u30bf\u30e0UI3
jp1.imdd.gui.settings.contentViews.System01CustomUI3.url = ./customUI/sample/customUI3.html
jp1.imdd.gui.settings.contentViews.System01CustomUI3.sid = _ROOT_AllSystems/_SYSTEM_SYSTEM01
```

### Important

- The maximum number of **Custom UI** tabs you can display for a single IM management node is 10.

## 6.2.4 Confirmation of the definition information

To check whether the setting for displaying a desired window when selecting an IM management node was written in the Intelligent Integrated Management Base definition file (`imdd.properties`), see the **Integrated Operation Viewer** window.

Select a target IM management node and check whether the intended window appears. If the definition information is incorrect, check the error details displayed on the console of the Web browser, and then take action.

## 6.3 Methods and objects that can be used in the user definition window

Load the following `js` files to use the interface provided by the Intelligent Integrated Management Base in `html` files for user-defined windows.

In Windows

**Manager-path** \public\assets\js\customContent.js

**Manager-path** \public\assets\js\vendor.js

In UNIX

/opt/jplimm/public/assets/js/customContent.js

/opt/jplimm/public/assets/js/vendor.js

For an example of how to use these files, see the usage example in [6.3.1 CustomContent.initialize](#).

The following table shows the methods and objects that can be used in the user definition window.

Table 6–2: Methods and objects that can be used in the user definition window

| Method name                                         | Functionality                                                                                                                             |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CustomContent.initialize</a>            | The method to execute the initialization processing by using the event handler received by the argument.                                  |
| <a href="#">CustomContent.simt</a>                  | Provides methods that manipulate the Simt data.                                                                                           |
| <a href="#">CustomContent.node</a>                  | The object that has the information on the IM management node that was selected in the integrated operation viewer.                       |
| <a href="#">CustomContent.options.props</a>         | The object that has the information on the client.                                                                                        |
| <a href="#">CustomContent.postActions</a>           | The method to execute the specified plug-in functions.                                                                                    |
| <a href="#">CustomContent.showMessage</a>           | The method to define a message to be displayed in the title and message display area.                                                     |
| <a href="#">CustomContent.selectNodeByTreeSid</a>   | The method to make the IM management node with the SID, which was specified in the argument, selected in the integrated operation viewer. |
| <a href="#">CustomContent.selectNodeByTargetSid</a> |                                                                                                                                           |

### 6.3.1 CustomContent.initialize

Functionality

This method executes the initialization processing by using the event handler received by the argument.

To draw the user definition window, always execute this method.

Format

```
initialize(handlers)
```

Argument

Defines the events to be obtained in the user definition window and transfers the names of functions to be executed when the events are obtained.

handlers

Event handlers

There are the following types of event handlers:

- `onSetup()`  
The setup event handler  
This event handler handles events that occur when the user definition window is drawn for the first time.
- `onActivate()`  
The activation event handler  
This event handler handles events that occur when the drawing of the user definition window is completed.
- `onInactivate()`  
The inactivation event handler  
This event handler handles events that occur when another window is displayed in the drawn user definition window.
- `onNodeSelect(node)`  
The node selection event handler  
This event handler handles events that occur when an IM management node is selected.
- `onStatusUpdate(node)`  
The node status update event handler  
This event handler handles events that occur when the status of the IM management node is updated regardless of the selected IM management node.

#### Return value

None

#### Use example

The following are some example cases:

1. When the `onSetup` event is received, the `Setup` function of the user definition window is run.
2. When the `onNodeSelect` event is received, the `NodeSelect` function of the user definition window is run.
3. When the `onActivate` event is received, the `Activate` function of the user definition window is run.

```
<html>
<script src="/assets/js/vendor.js"></script>
<script src="/assets/js/customContent.js"></script>
<script>

CustomContent.initialize({
  onSetup: Setup,
  onNodeSelect: NodeSelect,
  onActivate: Activate
});
function Activate() {
  alert("onActivate");
}
function NodeSelect () {
  alert("onNodeSelect ");
}
function Setup () {
  alert("onSetup");
}
</script>
</html>
```

## 6.3.2 CustomContent.simt

Provides methods that manipulate the Simt data; the following table shows the methods provided by CustomContent.simt:

Table 6–3: List of methods provided by CustomContent.simt

| No. | Method name | Description                                                                                                                                                                                           |
|-----|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | encodeValue | The method to URL-encode and return a character string.                                                                                                                                               |
| 2   | decodeValue | The method to URL-decode a URL-encoded character string and return the character string.                                                                                                              |
| 3   | filter      | The method to return an SID that contains a specified structured identifier as well as its value value.                                                                                               |
| 4   | get         | The method to return an SID that matches a specified structured identifier as well as its value value.                                                                                                |
| 5   | pack        | The method to join the class and name of a structured identifier and to return the generated structured identifier.                                                                                   |
| 6   | packHost    | The method to join the class and host name of a structured identifier and return the generated structured identifier.                                                                                 |
| 7   | unpack      | The method to split the structured identifier into classes and names and to return them.                                                                                                              |
| 8   | join        | The method to join structured identifiers and return the generated structured identifier.                                                                                                             |
| 9   | split       | The method to split the SID into structured identifiers and return them.                                                                                                                              |
| 10  | parse       | The method to split the SID into structured identifiers, further split the split structured identifiers into classes and URL-decoded names, and then to return the classes and the URL-decoded names. |
| 11  | data        | The method to generate an object from an SID and value value and to return the object.                                                                                                                |

### (1) encodeValue method

#### Functionality

The method to URL-encode and return symbols other than ., ~, -, and :, and non-alphanumeric characters in the string specified by the parameter.

#### Format

```
encodeValue (value)
```

#### Argument

value

The character string to be URL-encoded

#### Return value

The URL-encoded character string

### (2) decodeValue method

#### Functionality

This method decodes the character string specified in the parameter and then returns the character string.

#### Format

```
decodeValue (value)
```

#### Argument

value

The URL-encoded character string

#### Return value

The URL-decoded character string

### (3) filter method

#### Functionality

This method generates, from the array of SimtData objects (objects that summarize SIDs and value information) specified for the first parameter, a SimtData object whose SID includes the structured ID specified for the second parameter, and returns that generated SimtData object.

#### Format

```
filter(array, pattern)
```

#### Argument

array

The array of the SimtData object<sup>#</sup>

pattern

The structured identifier

#### Return value

The array of the SimtData object<sup>#</sup>

The SimtData<sup>#</sup> that has an SID that contains a structured identifier

If no object exists, an empty array is returned.

<sup>#</sup>: The SimtData object contains the following properties.

- sid: The character string that indicates an SID
- value: The object that stores the value of the SID

### (4) get method

#### Functionality

This method generates, from the array of SimtData objects (objects that summarize SIDs and value information) specified for the first parameter, a SimtData object whose SID matches the SID specified for the second parameter, and returns that generated SimtData object.

#### Format

```
get(array, sid)
```

#### Argument

array

The array of the SimtData object<sup>#</sup>

pattern

SID

#### Return value

The SimtData object<sup>#</sup>

This `SimtData#` object has an SID that matches the specified SID.

If no object exists, an empty null is returned.

**#:** The `SimtData` object contains the following properties.

- `sid`: The character string that indicates an SID
- `value`: The object that stores the value of the SID

## (5) pack method

### Functionality

This method encloses classes (without underscores) of the structured identifier specified by the first parameter with underscores (`_`), URL-encodes symbols other than `.`, `~`, `-`, and `:`, and non-alphanumeric characters in the name specified by the second parameter, joins the class and the name in this order, and then returns the generated structured identifier.

### Format

```
pack(key, value)
```

### Argument

`key`

The structured identifier class

`value`

The name of the structured identifier

### Return value

The character string of the structured identifier

## (6) packHost method

### Functionality

This method encloses classes (without underscores) of the structured identifier specified by the first parameter with underscores (`_`), URL-encodes symbols other than `.`, `~`, `-`, and `:`, and non-alphanumeric characters in the name (host name) specified by the second parameter, joins the class and the name in this order, and then returns the generated structured identifier.

If you create a structured identifier with a name other than a host name, use the `CustomContent.simt.pack` method.

### Format

```
packHost(key, value)
```

### Argument

`key`

The structured identifier class

`value`

The name of the structured identifier (host)

### Return value

The character string of the structured identifier

## (7) unpack method

### Functionality

This method splits the specified structured identifier into classes (without underscores) and URL-decoded names, and then returns the SimtIdUnit object that stores both.

### Format

```
unpack(simtId)
```

### Argument

`simtId`

The structured identifier

### Return value

The SimtIdUnit object<sup>#</sup>

<sup>#</sup>: The SimtIdUnit object contains the following properties.

- `key`: The class of a structured identifier (without underscores)
- `value`: The URL-decoded name of a structured identifier

## (8) join method

### Functionality

This method joins multiple structured identifiers, which are specified in the parameter, with a forward slash (/), and then returns the generated SID.

### Format

```
join(...simtId)
```

### Argument

`simtId`

The structured identifier.

### Return value

The character string of the SID

## (9) split method

### Functionality

This method splits the SID, which is specified to the parameter, with a forward slash (/), and then returns the structured identifiers.

### Format

```
split(sid)
```

### Argument

`sid`

SID

### Return value

The array of the character string of the structured identifier.

## (10) parse method

### Functionality

The method to store information (the SID, which is specified to the parameter, is split into structured identifiers, and the split structured identifiers are further split into classes and URL-decoded names from which underscores are eliminated) as a SimtIdUnit object, and then to return the array of stored SimtIdUnit object.

### Format

```
parse(sid)
```

### Argument

sid  
SID

### Return value

The array of the SimtIdUnit object<sup>#</sup>

<sup>#</sup>: The SimtIdUnit object contains the following properties.

- key: The class of a structured identifier (without underscores)
- value: The URL-decoded name of a structured identifier

## (11) data method

### Functionality

This method generates and returns a SimtData object from the SID and the value value that are specified for the parameters.

### Format

```
data(sid, value)
```

### Argument

sid  
SID  
value  
The value value

### Return value

The SimtData object<sup>#</sup> that put together the information of the SID and the value value

<sup>#</sup>: The SimtData object contains the following properties.

- sid: The character string that indicates an SID
- value: The object that stores the value value of the SID

## 6.3.3 CustomContent.node

This object has the information on the IM management node that was selected in the integrated operation viewer. The following table shows the properties of CustomContent.node.

Table 6–4: CustomContent.node properties

| No. | Property name                   | Description                                                                                              |
|-----|---------------------------------|----------------------------------------------------------------------------------------------------------|
| 1   | CustomContent.node.sid          | The tree SID information of the IM management node that was selected in the integrated operation viewer. |
| 2   | CustomContent.node.value.target | The SID information of the IM management node that was selected in the integrated operation viewer.      |
| 3   | CustomContent.node.value.label  | The label information of the IM management node that was selected in the integrated operation viewer.    |

### 6.3.4 CustomContent.options.props

The object that has the information on the client. The following shows the CustomContent.options.props properties.

Table 6–5: CustomContent.options.props properties

| No. | Property name                                   | Description                                                                                                               |
|-----|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| 1   | CustomContent.options.language                  | Information on the language class of the client                                                                           |
| 2   | CustomContent.options.clientId                  | Client ID information                                                                                                     |
| 3   | CustomContent.options.props.title <sup>#</sup>  | Setting information of title associated with the IM management node that was selected in the integrated operation viewer  |
| 4   | CustomContent.options.props.url <sup>#</sup>    | Setting information of url associated with the IM management node that was selected in the integrated operation viewer    |
| 5   | CustomContent.options.props.target <sup>#</sup> | Setting information of target associated with the IM management node that was selected in the integrated operation viewer |
| 6   | CustomContent.options.props.sid <sup>#</sup>    | Setting information of sid associated with the IM management node that was selected in the integrated operation viewer    |
| 7   | CustomContent.options.auth.jp1user              | Information on the logged-in JP1 user ID                                                                                  |
| 8   | CustomContent.options.auth.jp1token             | Information on the JP1 token of the logged-in JP1 user                                                                    |
| 9   | CustomContent.options.auth.token                | Information on the token of the client                                                                                    |
| 10  | CustomContent.options.auth.acl.permissions      | Array of the permissions of the logged-in JP1 user                                                                        |

<sup>#</sup>

The values defined for the following parameters in the Intelligent Integrated Management Base definition file (imdd.properties) are displayed.

| Property of the CustomContent.options.props | Parameters of the imdd.properties                        |
|---------------------------------------------|----------------------------------------------------------|
| CustomContent.options.props.title           | jp1.imdd.gui.settings.contentViews.<custom UI Id>.title  |
| CustomContent.options.props.url             | jp1.imdd.gui.settings.contentViews.<custom UI Id>.url    |
| CustomContent.options.props.target          | jp1.imdd.gui.settings.contentViews.<custom UI Id>.target |
| CustomContent.options.props.sid             | jp1.imdd.gui.settings.contentViews.<custom UI Id>.sid    |

## 6.3.5 CustomContent.postActions

### Functionality

This method runs functions of the specified plug-in.

### Format

```
postActions(method, sid, args)
```

### Argument

method

The name of the plug-in to be run

sid

The SID of the IM management node that is subject to plug-in processing

args

Specifies the value to be passed to the argument args.methodArgs of the plug-in functions to be executed. If no information is to be passed, an empty object ({} ) is specified.

### Return value

This object shows the result of the executed action. The content of the object varies depending on the executed action.

## 6.3.6 CustomContent.showMessage

### Functionality

This method displays the character string specified for the message argument in the message display area.

When the specified character string starts with the message ID of an error,  is displayed before the message.

When the specified character string starts with the message ID of a warning,  is displayed before the message.

In other cases,  is displayed before the message.

### Format

```
showMessage(message)
```

### Argument

message

The character string to be displayed in the message display area

### Return value

None

## 6.3.7 CustomContent.selectNodeByTreeSid

### Functionality

This method selects, in the integrated operation viewer, the IM management node with the tree SID, which was specified in the argument.

### Format

```
selectNodeByTreeSid(sid)
```

#### Argument

`sid`

The tree SID of the IM management node to be selected in the integrated operation viewer

#### Return value

None

### 6.3.8 CustomContent.selectNodeByTargetSid

#### Functionality

This method selects, in the integrated operation viewer, the IM management node with the SID, which was specified in the argument.

#### Format

```
selectNodeByTargetSid(sid)
```

#### Argument

`sid`

The tree SID of the IM management node to be selected in the integrated operation viewer

#### Return value

None

# 7

## Information Necessary to Use the Intelligent Integrated Management Base

This chapter describes the SIDs and json objects that are necessary to use the Intelligent Integrated Management Base, the adapter command information that is necessary to use user-created plug-ins, and the functionality provided to generate an IM management node tree. It also provides a sample plug-in and details regarding the control characters.

# 7.1 SID

A SID is an identifier that uniquely identifies components of each product retrieved using the configuration collection adapter command and a user-created plug-in. There are three types of SIDs: configuration information SIDs, tree SIDs, and event SIDs. SIDs are assigned by JP1/IM - Manager (Intelligent Integrated Management Base).

A unique SID is composed of class-name pairs, each of which is separated by a forward slash (/). A pair (structured identifier) is a combination of the class of a component element and the name of the component element in the class. The following example illustrates the structure of a SID.

Figure 7–1: Example illustrating the structure of a SID

The order of pairs is not arbitrary, which represents nested component elements in the product. For details, see the section that describes the information retrieved from each product in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*.

The following rules govern SIDs:

- The class and name of the SID can accept ASCII characters, except for the three types of characters of underscore (`_`), forward slash (`/`), and control codes.
- URL-encode any symbols other than the period (`.`), tilde (`~`), hyphen (`-`) and coron (`:`) as well as any non-alphanumeric characters. A URL-encoded SID must be URL-decoded.
- A host name must be specified in uppercase letters. Letters in a SID are case sensitive.
- The byte length of the SID ranges from 1 to 1,048,576 bytes (1 MB). The SID must not end with a forward slash (`/`).

## 7.1.1 Configuration information SID

A configuration information SID represents system configuration information.

There are different classes to configuration information SIDs, some of which are specific to each product while others are used commonly across products. The following table describes the reserved words for the class names used by the individual configuration information SIDs.

Table 7–1: Reserved words for the class names of configuration information SIDs

| No. | Applicable product | Class name <sup>#1</sup> | Description                   | Name to be specified <sup>#2</sup>              |
|-----|--------------------|--------------------------|-------------------------------|-------------------------------------------------|
| 1   | Common             | _HOST_                   | Indicates a host.             | The name of the host                            |
| 2   | JP1/AJS3           | _JP1AJS-M_               | Indicates JP1/AJS3 - Manager. | The name of the host running JP1/AJS3 - Manager |
| 3   |                    | _JP1AJS-A_               | Indicates JP1/AJS3 - Agent.   | The name of the host running JP1/AJS3 - Agent   |

| No. | Applicable product | Class name <sup>#1</sup> | Description                                                                                                                  | Name to be specified <sup>#2</sup>                                                                                |
|-----|--------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| 4   |                    | _JP1AJSMGR_              | Indicates JP1/AJS3 - Manager.                                                                                                | None                                                                                                              |
| 5   |                    | _JP1AJSAGT_              | Indicates JP1/AJS3 - Agent.                                                                                                  | None                                                                                                              |
| 6   |                    | _JP1AJSSCHE_             | Indicates the scheduler service of JP1/AJS3.                                                                                 | None                                                                                                              |
| 7   |                    | _JP1ROOTJOBNET_          | Indicates a root jobnet.                                                                                                     | The name of the root jobnet                                                                                       |
| 8   |                    | _JP1ROOTJOBNETDUMMY_     | Indicates that the preceding node or succeeding node is unknown in link information of a jobnet.                             | UNKNOWN                                                                                                           |
| 9   | JP1/AJS3<br>JP1/IM | _JP1SCHE_                | Indicates a scheduler service.                                                                                               | The name of the scheduler service                                                                                 |
| 10  |                    | _JP1JOBG_                | Indicates a job group.                                                                                                       | The name of the job group                                                                                         |

| 33  |                               | _NETWORKDEVICE_          | Indicates a network device.                        | Host name, IP switch name, or FC switch name  |
| 34  |                               | _JP1OA                   | Indicates JP1/OA.                                  | The name of the host running JP1/OA.          |
| 35  |                               | _JP1OA-A                 | Indicates a monitoring target of JP1/OA.           | The name of the monitoring target of JP1/OA   |
| 36  |                               | _JP1OAMGR_               | Indicates JP1/OA.                                  | None                                          |
| 37  |                               | _CONSUMER_               | Indicates a monitoring target (consumer).          | The name of the consumer                      |
| 38  |                               | _CONTAINERCLUSTER_       | Indicates a monitoring target (container cluster). | The name of the container environment cluster |
| 39  |                               | _CONTAINERNODE_          | Indicates a monitoring target (container node).    | The name of the container environment node    |
| 40  |                               | _SERVERCLUSTER_          | Indicates a monitoring target (cluster).           | The name of the cluster                       |
| 41  |                               | _HYPERVISOR_             | Indicates a monitoring target (hypervisor).        | The name of the hypervisor                    |
| 42  |                               | _VM_                     | Indicates a monitoring target (virtual machine).   | The name of the virtual machine               |
| 43  |                               | _STORAGE_                | Indicates a monitoring target (storage system).    | The name of the storage system                |

| No. | Applicable product | Class name <sup>#1</sup> | Description                                          | Name to be specified <sup>#2</sup>   |
|-----|--------------------|--------------------------|------------------------------------------------------|--------------------------------------|
| 44  |                    | _STORAGEVOLUME_          | Indicates a monitoring target (volume).              | The name of the volume               |
| 45  | JP1/SSO            | _JP1SSO-M_               | Indicates that the SID is related to an SSO manager. | The name of the host running JP1/SSO |
| 46  |                    | _JP1SSO-A_               | Indicates that the SID is related to an SSO agent.   | The name of the SSO agent host       |
| 47  |                    | _JP1SSOMGR_              | Indicates an SSO manager.                            | None                                 |
| 48  |                    | _JP1SSOAGT_              | Indicates an SSO agent.                              | None                                 |

#1

Each class name is 1 to 255 characters long.

#2

Each name must be 0 to 255 characters long, with the exception of the name specified for the object root node class, which must be 1 to 255 characters long.

The configuration information SID has, in addition to the value corresponding to the applicable class, additional information assigned to it in the form of a value specified for `value`. The following figure shows what the additional information looks like.

Figure 7–2: Example of additional information specified in a configuration information SID

`_JP1AJS-M_XXX/_HOST_XXX/_JP1SCHE_YYY," value" :{"label":ZZZ,...}`  
  
 additional information

The following table describes the additional information items specified in the configuration information SID.

Table 7–2: Additional information specified in the configuration information SID

| No. | Applicable product | Variable name    | Description                                                                                                                                                                                                                                                  |
|-----|--------------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Common             | component        | The component name. It is the <code>component</code> value of the <code>__configurationGet</code> method.<br>This information is specified in all configuration information SIDs.                                                                            |
| 2   |                    | jplResourceGroup | Specify a JP1 resource group name from 1 to 64 characters. The permitted characters are half-width alphanumeric characters and the following half-width symbols:<br>!#\$%&'()*+,-./@^_`{ }~<br>This variable can be omitted.                                 |
| 3   |                    | category         | Specify a category from 1 to 255 characters. The permitted characters are half-width alphanumeric characters. For the acceptable values, see <a href="#">Table 4-2 Category IDs that the category variable can accept</a> .<br>This variable can be omitted. |
| 4   |                    | subCategory      | Specify the abbreviated name of a product from 1 to 255 characters. The permitted characters are characters other than control characters. For JP1 products, this information is represented by a string starting with JP1/. This variable can be omitted.   |
| 5   |                    | visible          | Specify whether to show the component in the <b>Operating status</b> area. <ul style="list-style-type: none"> <li><code>true</code>: Show</li> <li><code>false</code>: Do not show</li> </ul> Specify <code>true</code> .                                    |

| No . | Applicable product | Variable name          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 6    |                    | label                  | Specify the display name of a component that is shown in the tree from 1 to 255 characters. The permitted characters are characters other than control characters. For JP1 products, this information is represented by a string starting with JP1/. This variable can be omitted.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 7    |                    | methods                | A list of plug-in functions that can work with the component through the plug-in. This information allows the function to be executed regardless of which product the plug-in belongs to. In order for this to work, it is important that you do not register a product-specific function. Make sure that the name of the function you register starts with an underscore (_).<br><br>The information for the client to identify whether the plug-in function can work with the node. Considering the scalability of the user plug-in, use <code>return</code> immediately without a plug-in that corresponds to a node causing an error if a method that is not found in <code>methods</code> is invoked. |
| 8    |                    | property               | Specify property information of each components in object format.<br>The number of elements you can specify ranges from 0 to 100. Property names can accept characters from 1 to 64 characters, other than control characters. Property values can accept characters from 1 to 255 characters, other than control characters. This variable can be omitted.<br><br>Example:<br><pre>"property":{"DataModelVersion":"yyy",...}</pre>                                                                                                                                                                                                                                                                        |
| 9    |                    | jplim_TrendData_labels | When referencing trend data, specifies the label name and label Value associated with SID in object format.<br>The number of elements that can be specified is 0 to 100. You can specify a property name that is from 1 to 255 control characters. The property Value can be from 1 to 2,595 non-control characters. This variable can be omitted.<br>Example of specification:<br><pre>"jplim_TrendData_labels":{"instance":"host1:9001"}</pre>                                                                                                                                                                                                                                                           |
| 10   | JP1/AJS            | jobExecAgentList       | Execution agent name information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## 7.1.2 Tree SID

A tree SID shows a path to a specific node in the system management tree. Specifically, it represents a path to one of the IM management nodes displayed in tree view.

A tree SID consists of the name of the class to which the component in question belongs and the component name relevant to the class (structured identifier), which, when put together with a slash (/), takes the form of a path to the corresponding node.

Unlike the configuration information SID, the tree SID must begin with `_ROOT_AllSystems`. The maximum number of hierarchies for the entire tree is 45 layers.

The following table lists classes used in a tree SID.

Table 7–3: Reserved words for the class names of the tree SID

| No. | Class name                 | Description                                                                              |
|-----|----------------------------|------------------------------------------------------------------------------------------|
| 1   | <code>_ROOT_</code>        | Indicates the root name of the system. Specify the root name of the system for the name. |
| 2   | <code>_SYSTEM_</code>      | Indicates a system. Specify the system name for the name.                                |
| 3   | <code>_HOST_</code>        | Indicates a host. Specify the host name for the name.                                    |
| 4   | <code>_CATEGORY_</code>    | Indicates a category. Specify the category name for the name.                            |
| 5   | <code>_SUBCATEGORY_</code> | Indicates a subcategory. Specify the subcategory name for the name.                      |
| 6   | <code>_OBJECT_</code>      | Indicates a management object. Specify the management object name for the name.          |
| 7   | <code>_HYPERVISOR_</code>  | Indicates a hypervisor name. Specify the host name of the hypervisor for the name.       |
| 8   | <code>_VM_</code>          | Indicates a VM. Specify the VM name for the name.                                        |

The following example illustrates the structure of a tree and tree SIDs.

Figure 7–3: Example illustrating the structure of a tree and tree SIDs

The following table describes the additional information for the tree.

Table 7–4: Additional information for the tree

| Variable name       | Description                                                                                                                                                                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>target</code> | The configuration information SID corresponding to the tree SID<br>When there is no configuration information SID corresponding to the tree SID, specify an empty array. The SID you specify must specify the SID that exists.                                                                                                   |
| <code>label</code>  | The display name of the component to be displayed on the tree<br>It inherits <code>label</code> of additional information for the SID or the information of <code>displayName</code> in the system node definition file ( <code>imdd_systemnode.conf</code> ).<br>If there is no such information, this variable can be omitted. |

| Variable name | Description                                                                                                                                                                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| resourceGroup | <p>The resource group</p> <p>It inherits label of additional information for the SID or the information of jplResourceGroup in the system node definition file (imdd_systemnode.conf).</p> <p>If there is no such information, this variable can be omitted.</p> |

For details about the system node definition file (imdd\_systemnode.conf), see *System node definition file (imdd\_systemnode.conf)* in *Chapter 2. Definition Files*.

### 7.1.3 JP1 Event SID

A JP1 event SID uniquely identifies each JP1 event.

The following table describes the classes of JP1 event SID.

Table 7–5: Reserved words for the class names of the JP1 event SID

| No. | Class name      | Description                                                                                                                                    |
|-----|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | _JP1IM          | Indicates a JP1IM event. Specify the IM manager host name for the name.                                                                        |
| 2   | _JP1IMSEQNO_    | Indicates a serial number in the integrated monitoring database. Specify the serial number in the integrated monitoring database for the name. |
| 3   | _JP1IMEVBSEQNO_ | Indicates a serial number in the event database. Specify the serial number in the event database for the name.                                 |

Example of the JP1 event SID

```
_JP1IM_imhost1/_JP1IMSEQNO_697/_JP1IMEVBSEQNO_7
```

### 7.1.4 Information retrieved from each product

Each product that links with JP1/IM - Manager (Intelligent Integrated Management Base) creates an SID from its configuration information retrieved with the adapter command and plug-in. The Intelligent Integrated Management Base manages created SIDs.

This section provides the types and formats of information retrieved from each product. The content of value depends on each product.

#### (1) Information retrieved from JP1/IM or JP1/Base

The following table lists the types and formats of the information retrieved from JP1/IM or JP1/Base.

Table 7–6: Types and formats of the information retrieved from JP1/IM or JP1/Base

| Type of information                                                       | Format                                                                                                              |
|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| The name of the host running JP1/IM - Manager (Integrated manager)        | {"sid": "_JP1IM_integrated-manager-host-name/_HOST_integrated-manager-host-name", "value": { ... }}, ...            |
| JP1/IM - Manager (Integrated manager) running on the host described above | {"sid": "_JP1IM_integrated-manager-host-name/_HOST_integrated-manager-host-name/_JP1IMMGR_", "value": { ... }}, ... |

| Type of information                                                                                                                                                                                | Format                                                                                                                                                                                                             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The host running the integrated manager and JP1/Base under the integrated manager                                                                                                                  | <code>{"sid": "_JP1IM_integrated-manager-host-name/_JP1BASE_Base-host-name/_HOST_Base-host-name", "value": {...}}, ...</code>                                                                                      |
| The integrated manager and JP1/Base under the integrated manager running on the host described above                                                                                               | <code>{"sid": "_JP1IM_integrated-manager-host-name/_JP1BASE_Base-host-name/_HOST_Base-host-name/_JP1BASEAGT_", "value": {...}}, ...</code>                                                                         |
| Log file traps and event log file traps performed on the host running the integrated manager and JP1/Base under the integrated manager                                                             | <code>{"sid": "_JP1IM_integrated-manager-host-name/_JP1BASE_Base-host-name/_HOST_Base-host-name/_JP1BASETRAP_", "value": {...}}, ...</code>                                                                        |
| The remotely monitored host under the integrated manager                                                                                                                                           | <code>{"sid": "_JP1IM_integrated-manager-host-name/_JP1IMRM_remotely-monitored-host-name/_HOST_remotely-monitored-host-name", "value": {...}}, ...</code>                                                          |
| Log file traps and event log file traps performed on the remotely monitored host under the integrated manager                                                                                      | <code>{"sid": "_JP1IM_integrated-manager-host-name/_JP1IMRM_remotely-monitored-host-name/_HOST_remotely-monitored-host-name/_JP1BASETRAP_", "value": {...}}, ...</code>                                            |
| The host running the base or relay manager under the integrated manager                                                                                                                            | <code>{"sid": "_JP1IM_integrated-manager-host-name/_JP1IMBASEMGR_base-/relay-manger-host-name/_HOST_base/relay-manger-host-name", "value": {...}}, ...</code>                                                      |
| JP1/IM - Manager (base or relay manager under the integrated manager) running on the host described above                                                                                          | <code>{"sid": "_JP1IM_integrated-manager-host-name/_JP1IMBASEMGR_base-/relay-manger-host-name/_HOST_base/relay-manger-host-name/_JP1IMMGR_", "value": {...}}, ...</code>                                           |

## 7.2 json objects

The following table lists json objects that can be accessed through the interface provided with the Intelligent Integrated Management Base.

Table 7–12: List of json objects

| Category                          | Object name                                                                           | Description                                                                                                                     | See                      |
|-----------------------------------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| Event                             | Event information                                                                     | An object to contain event information                                                                                          | <a href="#">7.2.1(1)</a> |
|                                   | Information for calling the monitor window of the linked product that issued an event | An object that represents the event information for calling the monitor window of the linked product                            | <a href="#">7.2.1(2)</a> |
|                                   | Event search condition                                                                | An object to contain event search conditions                                                                                    | <a href="#">7.2.1(3)</a> |
| IM management node                | IM management node tree information                                                   | An object to contain IM management node tree information                                                                        | <a href="#">7.2.2(1)</a> |
|                                   | IM management node                                                                    | An object to contain IM management node information                                                                             | <a href="#">7.2.2(2)</a> |
|                                   | IM management node link master                                                        | An object to contain IM management node link master information                                                                 | <a href="#">7.2.2(3)</a> |
| Trend data management             | Trend data                                                                            | Trend data objects handled by the Trend Data Management Service.                                                                | <a href="#">7.2.3(1)</a> |
|                                   | Label Set List                                                                        | A list object of label sets that can be obtained from Trend data Management Database through the Trend Data Management Service. | <a href="#">7.2.3(2)</a> |
| Auto execution of Response Action | Auto Response Action Definition                                                       | An object representing the information about auto Response Action definition.                                                   | <a href="#">7.2.4(1)</a> |
| Integrated agent Administration   | Integrated agent Info                                                                 | An object that represents information about the integration agent.                                                              | <a href="#">7.2.5(1)</a> |
| Dashboard                         | Dashboard Definition                                                                  | An object that represents information about a dashboard definition.                                                             | <a href="#">7.2.6(1)</a> |

### 7.2.1 Event

This section describes json objects for events.

#### (1) Event information object

##### Description

An object that contains event information

##### Format

```
{
  "sid": "JP1-event-SID",
  "value": [
    "event-attribute-name": "event-attribute-value", ...
  ],
  "title": [
    "event-attribute-name": "display-name-of-the-event-attribute", ...
  ]
}
```

```

    ],
    "type": [
        "event-attribute-name": "type-of-the-event-attribute", ...
    ],
    "monitor": [
        information-for-calling-the-monitor-window-of-the-linked-product-that-issued-an-event
    ]
}

```

## Members

The following table describes the members of this object.

**Table 7–13: Members of the event information object**

| No. | Member             | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|--------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | sid                | string    | Specifies the JP1 event SID that identifies the event uniquely. The format as follows:<br><div> <code>_JP1IM_manager-host-name/_JP1IMSEQNO_serial-number-in-the-integrated-monitoring-database/_JP1IMEVBSEQNO_serial-number-in-the-event-database</code> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2   | value              | Object[]  | Returns an array of pairs of event attributes and their values. If an attribute is not contained in the event, a string with the size of 0 bytes is returned as the attribute value.<br>The format of the list of event attributes and the attribute values returned by the <code>value</code> parameter is equivalent to that of values in the database, except for the time type event attribute <sup>#1</sup> and IP-address event attribute <sup>#2</sup> .<br>Event attributes of type time are returned in the ISO 8601 extended format ( <code>YYYY-MM-DDThh:mm:ssTZD</code> ).<br>When the event search API is run, this member returns event attributes that are specified with the <code>attrs</code> parameter.<br>When the event detailed information acquisition API is run, this member returns event attributes according to the settings in the definition file for extended event attributes. |
| 3   | title              | Object[]  | Returns the list of event attributes and their display names.<br>This member is returned when the event detailed information acquisition API is run. For details, see <a href="#">5.6.2 Event detailed information acquisition</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 4   | type <sup>#3</sup> | Object[]  | Returns the list of event attribute names and attribute types.<br>This member is returned when the event detailed information acquisition API is run. For details, see <a href="#">5.6.2 Event detailed information acquisition</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 5   | monitor            | Object[]  | Returns the information for calling the monitor window of the linked product that issued an event, if the event search API or event detailed information acquisition API is executed. For details, see <a href="#">7.2.1(2) Object of the information for calling the monitor window of the linked product that issued an event</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

#1

Time type event attributes are the registered timeframe (`B.TIME`), arrived timeframe (`B.ARRIVEDTIME`), start timeframe (`E.START_TIME`), and end timeframe (`E.END_TIME`). Those attributes are output in the ISO 8601 extended format (`YYYY-MM-DDThh:mm:ssTZD`). However, if start timeframe (`E.START_TIME`) and end timeframe (`E.END_TIME`) are non-numeric, or less than 0, they are output in string format.

#2

The event attribute of IP address type refers to the source IP address (`B.SOURCEIPADDR`) and the destination IP address (`B.DESTIPADDR`).

#3

The following table describes the attribute names and values returned by the `type` member:

| No. | type | Description                                                                                                                                                                                                               | Event attribute and relevant returned type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | None | String<br>The GUI is displayed in single-line text format.<br>Control characters (such as a line feed code) are replaced with space characters.                                                                           | Attributes that are not <code>text</code> , <code>html</code> , or <code>date</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Definition Files</i>.</p> |

### Important

In the REST API, the event attribute of a guide message is returned as an IM attribute (`E.@JP1IM_GUIDE`). The display name is shown as "ガイド" in Japanese and as `Guide` in English.

#### Event attributes of the consolidation start event

If the `consolidateEvent` request parameter of the event search API is set to `true`, the event attributes shown in the table below are set for the consolidation start event. They are not set for any event other than the consolidation start event. In addition, the event attributes of the consolidation start event are not output by the `jcoevtreport` command.

Table 7–14: Event attributes of the consolidation start event

| No. | Attribute                                        | Description                                                                                                                                                                                                                                 |
|-----|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <code>E.@JP1IM_CONSOLIDATION</code>              | Indicates whether the event is the consolidation start event. <ul style="list-style-type: none"> <li>• 1: consolidation start event</li> </ul>                                                                                              |
| 2   | <code>E.@JP1IM_CONSOLIDATION_STATUS</code>       | Indicates the status of the consolidation start event. <ul style="list-style-type: none"> <li>• 10: Normal/Resolved</li> <li>• 20: Warning/Notice/Information/Debug</li> <li>• 30: Error</li> <li>• 40: Emergency/Alert/Critical</li> </ul> |
| 3   | <code>E.@JP1IM_CONSOLIDATION_SEVERE_MIXED</code> | Indicates whether the consolidation event contains a mix of severe and non-severe events.                                                                                                                                                   |

| No. | Attribute                               | Description                                                                                                                                                                |
|-----|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |                                         | <ul style="list-style-type: none"> <li>• 0: Not mixed</li> <li>• 1: Mixed</li> </ul>                                                                                       |
| 4   | E.@JP1IM_CONSOLIDATION_DEALT_MIXED      | Indicates whether event statuses of the consolidation event are mixed. <ul style="list-style-type: none"> <li>• 0: Not mixed</li> <li>• 1: Mixed</li> </ul>                |
| 5   | E.@JP1IM_CONSOLIDATION_ACTCONTROL_MIXED | Indicates whether statuses of automatic actions of the consolidation event are mixed. <ul style="list-style-type: none"> <li>• 0: Not mixed</li> <li>• 1: Mixed</li> </ul> |

## (2) Object of the information for calling the monitor window of the linked product that issued an event

### Description

Is an object that represents the information for calling the monitor window of the linked product.

### Format

```
{
  "url": "URL-of-the-window-of-the-linked-product"
}
```

### Members

The following table describes the members of this object.

Table 7–15: Member of the object of the information for calling the monitor window of the linked product that issued an event

| No. | Member | Data type | Description                             |
|-----|--------|-----------|-----------------------------------------|
| 1   | url    | string    | URL of the window of the linked product |

## (3) Event search condition object

### Description

This object contains event search conditions. An event is determined to match an event search condition object if the event does not match any of the exclusion condition groups and matches at least one of the pass condition groups.

### Format

```
{
  "include": [pass-condition-group, ...],
  "exclude": [exclusion-condition-group, ...]
}
```

### Format of a pass or exclusion condition group

Specify an array of a pass or exclusion condition group. Specified event conditions are joined with the AND operator.

```
[
  { "key": "event-attribute-name", "ope": "comparison-condition", "val": "operand" }, ...
]
```

## Members

The following table describes the members of this object.

Table 7–16: Members of the event search condition object

| No. | Member  | Data type                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 1   | include | Object[]                  | Specify 0 to 5 pass condition groups for event search.<br>A pass condition group can contain 0 to 50 event conditions. For event conditions for extended attributes (specific information), a pass condition group can contain up to 5 conditions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 2   | exclude | Object[]                  | Specify 0 to 5 exclusion condition groups for event search.<br>An exclusion condition group can contain 0 to 50 event conditions. For event conditions for extended attributes (specific information), an exclusion condition group can contain up to 5 conditions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3   | key     | string                    | Specify the name of an event attribute that you want to compare. To specify a basic attribute, prefix the name with B . . To specify an extended attribute (common information or specific information), prefix the name with E . . This member is case-sensitive.<br>For the event attributes that are specifiable, see the <i>Attribute</i> column in <a href="#">Table 7-17 Combination of acceptable attribute names and comparison keywords</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 4   | ope     | string                    | Specify a comparison operator for the event attribute specified with key. As a comparison operator, you can specify one of the following values: BEGIN (begins with), IN (matches), NOTIN (does not match), SUBSTR (includes), NOTSUBSTR (does not include), REGEX (regular expression), and TRANGE (date and time). This member is case-sensitive.<br>The comparison conditions that can be specified for each event attribute are the same as those in the <i>Acceptable comparison keyword</i> column in <a href="#">Table 7-17 Combination of specifiable attribute names and comparison keywords</a> .<br>For details on the comparison conditions for the time type event attributes <sup>#</sup> , see <a href="#">Table 7-18 Comparison conditions for time type event attributes</a> and <a href="#">Table 7-19 List of time type event attributes</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 5   | val     | The value depends on key. | Specify a value (operand) to be compared against the value of the event attribute specified with key.<br>This member is case-sensitive. When multiple operands are allowed, specify them as an array of operands. When multiple operands are specified, the OR condition is used. However, when a regular expression is specified as a comparison keyword, the specification of multiple operands is not allowed.<br>Even if the operand accepts multiple specifications, an empty array or an array with null specified for an element cannot be specified.<br>When a half-width space character, a tab character, a line feed/carriage return character (CR or LF), or a percent sign (%) is used to specify an operand, it must be written as follows: <ul style="list-style-type: none"> <li>Half-width space character (0x20): %20</li> <li>Tab character (0x09): %09</li> <li>Line feed code (LF) (0x0a): %0a</li> <li>Carriage return code (CR) (0x0d): %0d</li> <li>Percent sign (%) (0x25): %25</li> </ul> You can specify a maximum of 4,096 bytes of operands per event condition and per event condition block (total length in bytes of all operands that are specified in the event condition block).<br>The comparison values (operands) that can be specified for each event attribute are the same as those in the <i>Operand</i> column in <a href="#">Table 7-17 Combination of acceptable attribute names and comparison keywords</a> .<br>Specify an array of operands if multiple operands are allowed. |

#

Time type event attributes are the registered timeframe (B . TIME), arrived timeframe (B . ARRIVEDTIME), start timeframe (E . START\_TIME), and end timeframe (E . END\_TIME).

**Table 7–17: Combination of acceptable attribute names and comparison keywords**

| N o. | Type            | Attribute                                      | Data type | Acceptable comparison keyword                                                                                                                                                         | Operand                                                                                                                                                                                                                                                                        |
|------|-----------------|------------------------------------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Basic attribute | Event ID (B . ID)                              | Numeric   | <ul style="list-style-type: none"> <li>Match</li> <li>Does not match</li> </ul>                                                                                                       | Multiple values are allowed. The maximum number of values you can specify is 100. Values must be specified in hexadecimal notation. The letters are case insensitive. However, letters in a regular expression are case sensitive. The acceptable range is from 0 to 7FFFFFFF. |
| 2    |                 | Registered reason (B . REASON)                 | Numeric   | <ul style="list-style-type: none"> <li>Match</li> <li>Does not match</li> </ul>                                                                                                       | Multiple values are allowed. The maximum number of values you can specify is 100.                                                                                                                                                                                              |
| 3    |                 | Source process ID (B . | No. | Type               | Attribute                         | Data type | Acceptable comparison keyword | Operand                                                                                                                           |
|-----|--------------------|-----------------------------------|-----------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 1   | Basic attribute    | Registered timeframe (B.TIME)     | Time      | Time                          | The operand can be specified in the same way as shown in <i>Table 7-18 Comparison conditions for time type event attributes</i> . |
| 2   |                    | Arrived timeframe (B.ARRIVEDTIME) | Time      | Time                          |                                                                                                                                   |
| 3   | Extended attribute | Start timeframe (E.START_TIME)    | Time      | Time                          |                                                                                                                                   |
| 4   |                    | End timeframe (E.END_TIME)        | Time      |                               |                                                                                                                                   |

## 7.2.2 IM management node

This section describes json objects for IM management node information.

## (1) IM management node tree object

### Description

An object that contains the information of an IM management node tree

### Format

```
{
  "meta":{
    "format":"file-type",
    "timestamp":"file-created-time"
    "componentName":"component-name",
    "hostName":"host-name",
    "version":"1"
  },
  "simtData":[
    {"sid":"IM-management-node-tree-SID"},...
  ]
}
```

### Members

The following table describes the members of this object.

Table 7–20: Members of the IM management node tree object

| No. | Member         | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----|----------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | meta           | array     | An array that stores file information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 2   | format         | string    | The file format. This is always set to <code>conf</code> . This attribute cannot be omitted.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 3   | timestamp      | string    | Returns the date and time when the file was created, as a UTC date time value in the ISO 8601 format. This attribute cannot be omitted. The time is based on the time of the JP1/IM - Manager server.                                                                                                                                                                                                                                                                                                                       |
| 4   | compornentName | string    | Specifies the name of the component from which IM management node information is retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 5   | hostName       | string    | Specifies the name of the host from which IM management node information is retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 6   | version        | string    | The version of the file. Always set this to 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 7   | simtData       | array     | An array that stores the SIDs of IM management nodes.<br>You can specify the SID of the IM management node for <code>target</code> , the label to be displayed for <code>label</code> , and the image file to be displayed as the node icon on the <b>Related node</b> tab for <code>iconName</code> , which together constitute the value of the tree SID.<br>For details about the names of image files, see 2.6.1 (7) <i>Icons for related nodes</i> in the <i>JP1/Integrated Management 3 - Manager GUI Reference</i> . |
| 8   | sid            | string    | Specifies the tree SID of the IM management node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### Output example

```
{
  "meta":{
    "format":"conf"
    "timestamp":"2018-11-11T00:00:00Z"
    "componentName":"/HITACHI/JP1/IMDD"
    "hostName":"host1"
  }
```

```

```

## (2) IM management node object

### Description

An object that contains IM management node information

### Format

```

{
  "meta":{
    "format":"file-type",
    "timestamp":"file-created-time"
    "componentName":"component-name",
    "hostName":"host-name",
    "version":"1"
  },
  "simtData":[
    {"sid":"IM-management-node-SID"}, ...
  ]
}

```

### Members

The following table describes the members of this object.

Table 7–21: Members of the IM management node object

| No. | Member    | Data type | Description                                                                                                                                                                                           |
|-----|-----------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | meta      | array     | An array that stores file information                                                                                                                                                                 |
| 2   | format    | string    | The file format. This is always set to <code>conf</code> .<br>This attribute cannot be omitted.                                                                                                       |
| 3   | timestamp | string    | Returns the date and time when the file was created, as a UTC date time value in the ISO 8601 format. This attribute cannot be omitted. The time is based on the time of the JP1/IM - Manager server. |

| No. | Member         | Data type | Description                                                                                                                                                                                                                                                               |
|-----|----------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | compornentName | string    | Specifies the name of the component from which IM management node information is retrieved.<br>It accepts alphanumeric characters and a forward slash (/).                                                                                                                |
| 5   | hostName       | string    | <ul style="list-style-type: none"> <li>For the IM management node object file<br/>Specifies the name of the host from which IM management node information is retrieved.</li> <li>For the IM management node object master file<br/>Always set this to master.</li> </ul> |
| 6   | version        | string    | The version of the file. Always set this to 1.                                                                                                                                                                                                                            |
| 7   | simtData       | array     | An array that stores the SIDs of IM management nodes.                                                                                                                                                                                                                     |
| 8   | sid            | string    | Specifies the SID of the IM management node.                                                                                                                                                                                                                              |

### Output example

```

}
```

## (3) IM management node link master object

### Description

An object that contains the information of an IM management node link master.

### Format

```
{
  "meta":{
    "format":"file-type",
    "timestamp":"file-created-time"
    "componentName":"component-name",
    "hostName":"host-name",
    "version":"1"
  },
  "links": [
    {
      "from": "preceding-node-SID",
```

```

        "to": "succeeding-node-SID",
        "type": "type-of-the-target"
    }, ...
]
}

```

## Members

The following table describes the members of this object.

Table 7–22: Members of the IM management node link master object

| No. | Member         | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|----------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | meta           | array     | An array that stores file information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2   | format         | string    | The file format. This is always set to <code>conf</code> . This attribute cannot be omitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 3   | timestamp      | string    | Returns the date and time when the file was created, as a UTC date time value in the ISO 8601 format. This attribute cannot be omitted. The time is based on the time of the JP1/IM - Manager server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## 7.2.3 Trend Data Management

### (1) Trend Data Object

#### Description

A json representing the trend data held by Trend data Management Database.

When the `jp1trendDataService.getTrendData` method is executed from the product plug-in, the trend data object is returned as the return data object via the trend data management service (Promscale).

For details of `jp1TrendDataService.getTrendData` method, see [4.5.17 jp1TrendDataService.getTrendData](#).

#### Format

```
{
  "status":"status",
  "data":{
    "resultType":"result-type",
    "result":[
      {"metric":{
        "Label-name":"label-value",
        ...
      }},
      "values":[
        [time,"value"],
        ...
      ]
    ]
  }
}
```

## Members

Members are listed in the following table.

Table 7–23: Trend data object members

| No. | Member             | Data type     | Description                                                                                           |
|-----|--------------------|---------------|-------------------------------------------------------------------------------------------------------|
| 1   | status             | string        | A string that represents the retrieved result.<br>If the acquisition is successful, "success" is set. |
| 2   | resultType         | string        | A string that represents the type of data retrieved.<br>Fixed "matrix" is set.                        |
| 3   | result             | array         | An array that represents the trend data.                                                              |
| 4   | metric             | array         | An array that contains the labels attached to the trend data.                                         |
| 5   | <i>label name</i>  | <i>string</i> | <i>The name of the label given to the trend data.</i>                                                 |
| 6   | <i>label value</i> | string        | The value of the label given to the trend data.                                                       |
| 7   | values             | array         | An array that represents the performance data for each time.                                          |
| 8   | time               | Numeric       | The time of the performance data (the number of seconds elapsed since January 1, 1970 00:00:00 UTC).  |
| 9   | values             | Numeric       | The value of the performance data.                                                                    |

## Output example

```
{
  "status": "success",
  "data": {
    "resultType": "matrix",
    "result": [
      { "metric": {
        "__name__": "foo",
        "job": "hoge"
      } },
      { "values": [
        [1617436800, "100"],
        [1617436830, "100"],
        [1617436860, "100"],
        [1617436890, "100"]
      ] }
    ]
  }
}
```

## (2) Label Set List Object

### Description

A json object that lists the label sets for trend data held by Trend data Management Database.

When you Execute `jplTrendDataService.getLabelList` method from product plugin, the label set list object is returned as a data object for the return Value through the Trend Data Management Service (Promscale).

For Detail of `jplTrendDataService.getLabelList` method, see [4.5.18 jplTrendDataService.getLabelList](#).

**Format**

```
{
  "status": "Status",
  "data": [
    {
      "Label name": "Label Value",
      ...
    },
    {
      "Label name": "Label Value",
      ...
    },
    ...
  ]
}
```

Within the above definition, the following part shows a single set of labels.

```
{
  "Label name": "Label Value",
  ...
},
```

**Members**

Members are listed in the following table.

Table 7–24: Trend data object members

| No. | Member      | Data type | Description                                                                                                             |
|-----|-------------|-----------|-------------------------------------------------------------------------------------------------------------------------|
| 1   | status      | string    | A character string representing the result of the acquisition.<br>If the acquisition is successful, "success" is Setup. |
| 2   | Label name  | string    | The name of the label attached to the trend data.                                                                       |
| 3   | Label Value | string    | The value of the label attached to the trend data.                                                                      |

**Output example**

```
{
  "status" : "success",
  "data" : [
    {
      "__name__" : "up",
      "job" : "prometheus",
      "instance" : "localhost:9090"
    },
    {
      "__name__" : "up",
      "job" : "node",
      "instance" : "localhost:9091"
    }
  ]
}
```

## 7.2.4 Auto execution of response action

### (1) Auto Response Action definition Object

#### Description

An json object representing information about automated Response action definition. The size of this object is limited to less than 10MB.

#### Format

```
{
  "meta":{
    "version":"Version information"
  },
  "actions":[
    {"actionGroup":"Action grouping",
     "actionId":"Action ID",
     "label":"Action name",
     "description":"Comment",
     "valid":"Enable /Disable",
     "conditions":[
       {"type":"type",
        "key":"Attribute name",
        "ope":"Operators",
        "val":["Attribute value",...]}
     ],
     ...
  ],
  "action":{
    "type":"Action type",
    "params":"Action Description"
  }
},
...
]
```

When specifying a character string in the items in the above definition, if " or \ is included as a normal character, it is preceded by \, and it is set to \", \\\.

#### Definitions

#### Members

Members are listed in the following table.

Table 7–25: Members of Auto Response Action Definition Objects

| No. | Member  | Data type | Needing to specify | Description                                                                                                                                  |
|-----|---------|-----------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | meta    | object    | Required           | Objects that Setup Common data for the entire auto response Action                                                                           |
| 2   | version | string    | Required           | Specify Version.<br>Specify 1 as the fixed Value.                                                                                            |
| 3   | actions | object[]  | Optional           | Array of auto Response Action Setup that Setup the conditions that trigger Response Action to Execute and Execute content of Response Action |

| No. | Member |             | Data type | Needing to specify | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|--------|-------------|-----------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |        |             |           |                    | The number of items that can be specified is 0 to 1000 (the default Value).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 4   |        | actionGroup | int       | Required           | <p>specifies the number of the Response Action grouping as an integer from 0 to 9.</p> <p>The size of the number in Response Action group is independent of the precedence of Execute conditional determination and Response Action's Execute condition.</p> <p>You can specify one execution of Response Action per group, allowing you to execute up to 10 Response Action at the same time for a single system status change.</p>                                                                                                                                                                                                                                                 |
| 5   |        | actionId    | int       | Required           | Specifies Action ID to be uniquely allocated for each automated ResponseAction Setup. Value can be an integer from 0 to 2,147,483,647.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 6   |        | label       | string    | Required           | Specifies Action name to identify the auto Response Action Setup as a character string from 1 to 50 bytes. You can specify any character other than the control character (0x00 to 0x1F, 0x7F to 0x9F).                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 7   |        | description | string    | Optional           | <p>Specify Comment (explanation of Response Action to Execute) for the auto Response Action Setup as a character string from 1 to 1040 bytes. You can specify any character other than the control character (0x00 to 0x1F, 0x7F to 0x9F).</p> <p>This field has no effect on auto execution of response Action.</p>                                                                                                                                                                                                                                                                                                                                                                 |
| 8   |        | valid       | boolean   | Optional           | <p>Specifies whether to Enable the applicable auto Response Action Setup.</p> <ul style="list-style-type: none"> <li>• True: Enable</li> <li>• False: Disabled</li> </ul> <p>By default, "true" is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 9   |        | conditions  | object[]  | Required           | <p>Specifies the criteria that triggers execution of Response Action.</p> <p>The number of conditions that can be specified is 1 to 256. If more than one execution condition is specified, it is determined that execution condition is Match when all event conditions are met (AND condition).</p>                                                                                                                                                                                                                                                                                                                                                                                |

■ Value that can be specified in execution criteria of Action

For Source IP address event conditions, in addition to IPv4 address conditions, you can specify IPv6 address conditions in IPv6 address notation (alphabetic characters in IPv6 notation must be specified in lowercase).

The following table lists IP address conditions that can be specified for Source IP address event conditions:

| Source IP address | Example of specification                | Can be specified? |
|-------------------|-----------------------------------------|-------------------|
| IPv4 addressing   | 11.22.33.44                             | Yes               |
| IPv6 addressing   | 0011:2233:4455:6677:8899:aabb:ccdd:eeff | Yes               |
|                   | 0011:2233:4455:6677:8899:AABB:CCDD:EEFF | No                |

| Source IP address    |                            | Example of specification | Can be specified? |
|----------------------|----------------------------|--------------------------|-------------------|
|                      |                            | 2012:7:8::a:b            | No                |
| Special IPv6 address | IPv4 projection addressing | ::ffff:11.22.33.44       | No                |
|                      | IPv6 projection addressing | ::11.22.33.44            | No                |

      "description":"To execute collecting data when an error is detected by a particular Event ID",
      "valid":true,
      "conditions":[
        {
          "type":"event",
          "key":"B.ID",
          "ope":"IN",

```

```

        "val":["00004860","00004861"]
    },
    {
        "type":"event",
        "key":"E.SEVERITY",
        "ope":"IN",
        "val":["Error","Emergency"]
    }
],
"action":{
    "type":"cmd",
    "params":{
        "host":"${event:EVHOST:}",
        "cmd":"\"C:\\Program Files (x86)\\Hitachi\\JP1IMM\\tools\\jim_log
\\\" -f C:\\temp -q",
        "envFile":"C:\\tmp\\envFile.txt"
    }
}
}
]
}

```

## 7.2.5 Integrated agent administration

### (1) Integrated agent Info object

#### Description

A json object representing integrated agent info.

#### Format

```

{
    "agentid": agent ID,
    "agenthost": integrated agent host name,
    "os": OS name,
    "installpath": Installation path,
    "imversion": version of integrated agent,
    "managerhost": Manager Host name,
    "registeredtime": registration date and time,
    "addons": [
        {
            "addonName": Function name,
            "enabled ": Status
        }, ...
    ]
}

```

#### Members

Members are listed in the following table.

Table 7–26: Members of integrated agent info object

| No. | Member  | Data type | Description                       |
|-----|---------|-----------|-----------------------------------|
| 1   | agentid | string    | Specifies ID of integrated agent. |

| No. | Member         | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|----------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | agenthost      | string    | Specifies Host name of integrated agent.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 3   | os             | string    | Specifies OS of the host for integrated agent.<br>(Ex: windows, linux)                                                                                                                                                                                                                                                                                                                                                                                                       |
| 4   | installpath    | string    | Specifies Installation path of JP1/IM - Agent installed on integrated agent host.                                                                                                                                                                                                                                                                                                                                                                                            |
| 5   | imversion      | string    | Specifies Version (VVRSS) of JP1/IM - Agent as a six-digit number.                                                                                                                                                                                                                                                                                                                                                                                                           |
| 6   | managerhost    | string    | Specifies Host name of integrated agent manager.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 7   | registeredtime | string    | Specifies UTC time in ISO 8601 format as the registration date and time of integrated agent data.<br>The registration date and time will be updated when JP1/IM - Agent is started after the following operations are performed: <ul style="list-style-type: none"> <li>• Installation of JP1/IM - Agent</li> <li>• Version upgrade install of JP1/IM - Agent</li> <li>• Delete JP1/IM - Agent on the JP1/IM agent list screen of the Integrated Operation Viewer</li> </ul> |
| 8   | addons         | object[]  | Specifies an array of add-on information objects.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 9   | addonName      | string    | Specify the add-on name.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 10  | enabled        | boolean   | Specify whether to Enable the add-on function. <ul style="list-style-type: none"> <li>• True: Enabled</li> <li>• False: Disabled</li> </ul>                                                                                                                                                                                                                                                                                                                                  |

### Output example

```
{
  "agentid": "RENEMzNENDg5RkQyNEM2OT",
  "agenthost": "agenthostA",
  "os": "windows",
  "installpath": "C:\\Program Files\\Hitachi\\jplima",
  "imversion": "130000",
  "managerhost": "managerhostA",
  "registeredtime": "2020-03-01T00:00:00Z",
  "addons": [
    {
      "addonName": "Windows metric collector(Windows exporter)",
      "enables": true
    }, ...
  ]
}
```

## 7.2.6 Dashboard

Describes a JSON object that shows dashboard information.

### (1) Dashboard Definition Object

#### Function

An object that represents information about a dashboard definition.

## Type

```
{
  "id": ID,
  "title": Titled,
  "memo": Tree SID,
  "data": Panels,
  "owner": owner,
  "scope": public scope,
  "createTime": Creation date and time,
  "updateTime": Updated time
}
```

When specifying a character string in the above definition, if you want to include "", "{", "}", "[", "]", and "\" as regular characters, use "\\\"", "\\{", "\\}", "\\[", "\\]", and "\\\".

## Member

Members are listed in the following table.

**Table 7–27: Dashboard definition object members**

| Item number | Member | Data type | Description                                                                                                                                                                                                                                            |
|-------------|--------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1           | id     | int       | Dashboard ID                                                                                                                                                                                                                                           |

## 7.3 Configuring the adapter command

This chapter describes the configuration of the adapter command.

Note that JP1/Base is needed for the execution environment of the adapter command.

### 7.3.1 Setting up the adapter command

#### (1) Setup

1. Execute the setup command provided by each linked product.
2. The adapter command settings file is generated in the following location:

In Windows:

*JP1/Base-installation-folder*#\plugin\conf

In UNIX:

/opt/jp1base/plugin/conf

#

The folders below are the default installation locations for each product. Note that *system-drive*: \ProgramData represents the location determined by the OS environment variable during installation, and thus it may vary depending on your environment.

In an x86 environment: *system-drive*: \Program Files\Hitachi\JP1Base

In an x64 environment: *system-drive*: \Program Files (x86)\Hitachi\JP1Base

#### Important

- In Windows, the installation directory of JP1/Base is retrieved from the following registry entry:  
HKEY\_LOCAL\_MACHINE\SOFTWARE\HITACHI\JP1BASE\PATHNAME\PATH00
- If there is a file with the same name at the location where the file is to be stored, the file is overwritten.
- Do not stop the JP1/Base service.

#### (2) Unsetup

1. Execute the unsetup command provided by each linked product.
2. Remove the adapter command settings file manually.

#### Important

- Do not stop the JP1/Base service.
- When you uninstall a linked product, the adapter command settings file is also uninstalled.

## 7.3.2 Adapter command settings file

This section describes the name of the adapter command settings file, a component identifier, and notes on the adapter command settings file.

### (1) Naming rule of the adapter command settings file

The following is the naming rule of the adapter command settings file:

`Adaptercomponent-identifier.conf`

For example, if the component identifier is `/HITACHI/JP1/BASE/GETHOSTNAME`, the adapter command settings file name will be `Adapter_HITACHI_JP1_BASE_GETHOSTNAME.conf`.

### (2) Component identifier

A component identifier is a string for identifying a component of each product. A specific component identifier is assigned to each component of the individual linked product.

If a product name specified by `product` in the target host definition file for configuration collection partially matches a component identifier, the Intelligent Integrated Management Base executes the adapter command plug-in of the component to collect configuration information.

`SYSTEM`, `DEFAULT`, and a string starting with `HITACHI` are reserved identifiers. Follow the rules below when creating a component identifier:

- Identifier size: Up to 240 bytes
- Available characters: ASCII numbers, uppercase alphabetic letters, and forward slash (/)

### (3) Setting items of the adapter command settings file

For details on the settings items in the adapter command settings file, see [Table 4-4 Setting items of the adapter command settings file](#).

### (4) Notes on the adapter command settings file

- Even if a correct absolute path to the adapter command is not specified as the path in the `cmdpath` attribute of the adapter command settings file, the `jddcreatetree` command does not cause an error. Make sure you verify that a correct path to the adapter command is specified in the development environment before operation.
- You do not have to enclose the path in double quotation marks or other characters even if the absolute path in the `cmdpath` attribute contains any space characters.
- A single row can contain a maximum of 4,096 characters.
- If there is more than one label with the same name, an error occurs.
- If a label is omitted, an error occurs.
- If even a single error exists in the file, the file is no longer valid.
- The file is terminated with the line feed character.
- The file can contain ASCII characters only.
- When you specify a label, a white space or tab character is not allowed at the beginning of the row.
- Any row containing white space or tab characters only is ignored.

## 7.4 IM management node tree generation function

The IM management node tree generation function is one of the functions to get IM management node related information. IM management node related information can be obtained through the three functions of system configuration information collection, IM management node link generation, and IM management node tree generation.

The system configuration information collection function collects system configuration information of a linked product using adapter commands and plug-ins. The IM management node link generation function generates relations between configurations, based on the collected configuration information. For details, see [4.4.4\(6\) \\_\\_createLink method](#).

The following table lists and describes the input and output information of the IM management node tree generation function.

Table 7–34: Input information of the IM management node tree generation function

| No. | Input information                                                                              | Description                                                                                                                                                                                                                                                           |
|-----|------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | System configuration information                                                               | System configuration information of a linked product that was collected using adapter commands and plug-ins.<br>The system configuration information is shown in the SID and additional information of the SID. For details on the SID, see <a href="#">7.1 SID</a> . |
| 2   | System node definition file ( <code>imdd_systemnode.conf</code> )                              | Definition information of the hierarchical structure consisting of the system, subsystems, and underlying given nodes.                                                                                                                                                |
| 3   | Category name definition file for IM management nodes ( <code>imdd_category_name.conf</code> ) | Definition information of the names and display orders of categories that appear in sunburst chart format or tree format.                                                                                                                                             |
| 4   | Host name definition file ( <code>imdd_host_name.conf</code> )                                 | Definition information for mapping alias names to actual host names, if a product in which an alias name can be assigned to a host name is added to the configuration of IM management nodes.                                                                         |

Table 7–35: Output information of the IM management node tree generation function

| No. | Input information | Description                                                                                                                                                                                                                                                                                                                                                           |
|-----|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Tree information  | Information necessary to show IM management nodes in sunburst chart format or in tree format.<br>The IM management node tree file ( <code>imdd_nodeTree.json</code> ) that contains tree information is generated.<br>The tree information is shown in the tree SID and additional information of the tree SID. For details on the SID, see <a href="#">7.1 SID</a> . |

For details on the system node definition file (`imdd_systemnode.conf`), the category name definition file for IM management nodes (`imdd_category_name.conf`), and the host name definition file (`imdd_host_name.conf`), see [System node definition file \(`imdd\_systemnode.conf`\)](#), [Category name definition file for IM management nodes \(`imdd\_category\_name.conf`\)](#), and [Host name definition file \(`imdd\_host\_name.conf`\)](#) in [Chapter 2. Definition Files](#).

The IM management node tree generation function has the three functions of system node generation, node generation, and tree SID conversion.

## 7.4.1 System node generation function

The function generates tree information from the root node to the system node, based on the system configuration information and the information in the system node definition file (`imdd_systemnode.conf`).

The following table shows the input and output information of the system node generation function.

Table 7–36: Input and output information of the system node generation function

| No. | Input information / Output information |                                                                   | Description                                                                                                                                                                                                                                                       |
|-----|----------------------------------------|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Input information                      | System configuration information                                  | System configuration information of a linked product that was collected with adapter commands and plug-ins. The system configuration information is shown in the SID and additional information of the SID. For details on the SID, see <a href="#">7.1 SID</a> . |
| 2   |                                        | System node definition file ( <code>imdd_systemnode.conf</code> ) | Definition information of the hierarchical structure consisting of the system, subsystems, and underlying given nodes                                                                                                                                             |
| 3   | Output information                     | Tree information from the root node to the system node            | Information necessary to show IM management nodes in sunburst chart format or in tree format. The tree information is shown in the tree SID and additional information of the tree SID. For details on the SID, see <a href="#">7.1 SID</a> .                     |

The system node generation function has the system node generation function using a file and one using a plug-in. Each of the functions is described below.

- System node generation function using a file

Based on the information on the system node contained in the system node definition file (`imdd_systemnode.conf`), the tree SID and additional information of the system node are generated. The tree SID and additional information of `All Systems` of the root node are also generated.

The following table lists the additional information to be generated of the root node and system node.

Table 7–37: Additional information of the root node and system node

| No. | Node       | Structured identifier |
|-----|------------|-----------------------|
| 1   | rootnode   | target                |
| 2   |            | label <sup>#</sup>    |
| 3   | systemnode | target                |
| 4   |            | resourceGroup         |
| 5   |            | label                 |

<sup>#</sup> Specify `All Systems`.

- System node generation function using a plug-in

If you create a system node other than the system node defined in the system node definition file, use the system node generation function using a plug-in to generate the tree SID and additional information of the system node.

For example, if a product that links with JP1/IM manages something similar to the concept of the JP1/IM system and the users have already been using the product, use a plug-in to generate a system node.

The following table shows what to do on the additional information of the newly created tree SID in relation to the additional information of the tree SID already created if the tree SID of the system node created with the plug-in is the same as the one of the system node created based on the system node definition file.

Table 7–38: Action on additional information when the tree SID is duplicated

| No. | Structured identifier | Action                                                           |
|-----|-----------------------|------------------------------------------------------------------|
| 1   | target                | add                                                              |
| 2   | label                 | label of the tree SID already generated takes precedence         |
| 3   | resourceGroup         | resourceGroup of the tree SID already generated takes precedence |

## 7.4.2 Node generation function

The function generates tree information of all nodes under the system node of a tree, joins it with the tree information from the root node to the system node generated by the system node generation function, and generates tree information of the entire tree.

The following table shows the input and output information of the node generation function.

Table 7–39: Input and output information of the node generation function

| No. | Input information / Output information |                                                                                    | Description                                                                                                                                                                                                                                                           |
|-----|----------------------------------------|------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Input information                      | System configuration information                                                   | System configuration information of a linked product that was collected using adapter commands and plug-ins.<br>The system configuration information is shown in the SID and additional information of the SID. For details on the SID, see <a href="#">7.1 SID</a> . |
| 2   |                                        | Tree information to the system node                                                | Tree information generated by the system node generation function                                                                                                                                                                                                     |
| 3   |                                        | Category name definition file for IM management nodes<br>(imdd_category_name.conf) | A file that defines the names and orders of IM management node categories for management groups when data collected by the Intelligent Integrated Management Base is shown in sunburst chart format or in tree format                                                 |
| 4   |                                        | Host name definition file (imdd_host_name.conf)                                    | Definition information for mapping alias names to actual host names, if a product in which an alias name can be assigned to a host name is added to the configuration of IM management nodes                                                                          |
| 5   | Output information                     | Tree information                                                                   | Information necessary to show IM management nodes in sunburst chart format or in tree format.<br>The tree information is shown in the tree SID and additional information of the tree SID. For details on the SID, see <a href="#">7.1 SID</a> .                      |

The node generation function consists of the node generation function using JP1/IM and the node generation function using a plug-in. Each of the functions is described below.

- Node generation function using JP1/IM

JP1/IM generates the tree SID and additional information of the nodes under the system node. The following table shows additional information of nodes under the system node to be generated.

Table 7–40: Additional information of nodes under the system node

| No. | Structured identifier |
|-----|-----------------------|
| 1   | target                |
| 2   | resourceGroup         |
| 3   | label                 |

- Node generation function using a plug-in

A plug-in can generate the tree SID of the entire tree. When a plug-in generates a node, use the `__createTreeNode` method. For details, see [4.4.4\(3\) `\_\_createTreeNode` method](#).

The following table shows what to do on the additional information of the newly created tree SID in relation to the additional information of the tree SID already created if the tree SID under the system node created by the plug-in is the same as the one under the system node created using JP1/IM.

Table 7–41: Action on additional information when the tree SID is duplicated

| No. | Structured identifier | Action                                                           |
|-----|-----------------------|------------------------------------------------------------------|
| 1   | target                | add                                                              |
| 2   | label                 | label of the tree SID already generated takes precedence         |
| 3   | resourceGroup         | resourceGroup of the tree SID already generated takes precedence |

## (1) Default tree SID

If a node does not meet the definition of the system node and is not generated by a plug-in, the tree nodes of the object root node and objects are generated according to the following rule for creating the default tree SID:

`_ROOT_AllSystems/_SYSTEM_type-of-the-object-root-node/_type-of-the-object-root-node_name-of-the-object-root-node/_CATEGORY_category-of-the-object/_SUBCATEGORY_subcategory-of-the-object/_OBJECT_name-of-the-object`

The following table shows the default tree SIDs.

Table 7–42: Default tree SIDs

| No. | IM management node type | Structured identifier name                                                                                                                              | label value                                                                                                                          | Creation condition                                                                                                                                                                           |
|-----|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | SYSTEM                  | Value of the <code>meta.objectRoot.defaultSystem.name</code> configuration information#<br>Type of the object root node if the above value is not found | Value of the <code>meta.objectRoot.defaultSystem.label</code> configuration information#<br>No value if the above value is not found | If the SID of configuration information contains the structured identifier of the object root node and <code>meta.objectRoot.defaultSystem#</code> of the configuration information is found |
| 2   | Object root node type   | Name of the object root node                                                                                                                            | label value in the configuration information                                                                                         | If the SID of configuration information contains the structured identifier of the object root node                                                                                           |
| 3   | CATEGORY                | Additional information's <code>category</code> value in the configuration information                                                                   | Name resolved by the category name definition file for IM management nodes based on the additional information's                     | If the additional information in the configuration information has <code>category</code>                                                                                                     |

| No. | IM management node type | Structured identifier name                                                                                                                       | label value                                     | Creation condition                                                                                                                                    |
|-----|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |                         |                                                                                                                                                  | category value in the configuration information |                                                                                                                                                       |
| 4   | SUBCATEGORY             | Additional information's subCategory name in the configuration information                                                                       | None                                            | If the additional information in the configuration information has category and subCategory                                                           |
| 5   | OBJECT                  | Name that joins <i>Class</i> and <i>Name</i> of a structured identifier under the object root node with the SID in the configuration information | label value in the configuration information    | If the SID of configuration information contains the structured identifier of the object root node and its subordinate structured identifier is found |

#: For details on `meta.objectRoot.defaultSystem`, see *List of configuration information to be returned in 4.4.4(1)* [\\_\\_configurationGet method](#).

The tree structure is shown in the following figure.

Figure 7–4: Tree structure

In the Intelligent Integrated Management Base, the tree structure is maintained in JSON format. This tree structure is referred to as a *tree object*. The following tree object depicts the tree structure shown in the figure above:

```
{
  "meta": {
    "format": "conf",
    "timestamp": "2018-11-11T11:11:11Z"
  }
}
```

```

    },
    "simtData":[
      {"sid": "_ROOT_AllSystem", "value": {"target": [], "label": ""}},
      {"sid": "_ROOT_AllSystem/_SYSTEM_SystemA", "value": {"target": [], "resourceGroup": ["userA"], "label": "System A"}},
      {"sid": "_ROOT_AllSystem/_SYSTEM_SystemA/_HOST_HostA", "value": {"target": [], "label": "Host A"}},
      {"sid": "_ROOT_AllSystem/_SYSTEM_SystemA/_HOST_HostA/_CATEGORY_Job", "value": {"target": [], "label": "Job"}},
      {"sid": "_ROOT_AllSystem/_SYSTEM_SystemA/_HOST_HostA/_CATEGORY_Job/_SUBCATEGORY_SubCategoryA", "value": {"target": [], "label": ""}},
      {"sid": "_ROOT_AllSystem/_SYSTEM_SystemA/_HOST_HostA/_CATEGORY_Job/_SUBCATEGORY_SubCategoryA/_OBJECT_ServiceA", "value": {"target": [], "label": "Service A"}},

      {"sid": "_ROOT_AllSystem/_HOST_HostB/_CATEGORY_Job/_OBJECT_ServiceB", "value": {"target": ["_JP1IM_IMMGR/_JP1BASE_HostB/_HOST_HostB/_JP1BASE_AGT_"], "label": "Service B"}}
    ]
  }

```

### Tip

The order in which the `simtData` objects are arranged signifies the order in which the components in the same layer appear in the window.

## 7.4.3 Tree SID conversion function

The function retrieves SID information from collected system configuration information and the system node definition file (`imdd_systemnode.conf`) and converts it into the tree SID.

Multiple tree SIDs are generated depending on SID patterns of the system node definition information as input information and the definition in the system node definition file (`imdd_systemnode.conf`).

For details about the system node definition file (`imdd_systemnode.conf`), see [System node definition file \(`imdd\_systemnode.conf`\)](#) in *Chapter 2. Definition Files*.

The following table lists tree SIDs to be generated.

Table 7–43: Tree SIDs to generated

| No. | Input information              |                                                                                                                                              | Category and subcategory information      | Tree SIDs to be generated                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Legend:**

S1/S2/...Sn: Tree SIDs that represent the root node and the system node

A1, A2, ..., An: Structured identifier

Ax: Structured identifier that contains HOST and object root node types

C, SC: Structured identifier that represents a category and subcategory

Y1, Y2, ..., Yn: Structured identifiers that represent object nodes

## Important

If a host other than the host with the name specified in the system node definition file (imdd\_systemnode.conf) or anything other than the name that corresponds to the object node type exists in the SID, it is placed under the root node, not the system node.

## 7.5 Sample plugin

This section describes to Sample plugin.

### 7.5.1 Assumed operation / configuration

Manage the management tool A that monitors the Manager-Agent method with the Intelligent Integrated Management Base.

The management tool A monitors the logs and the performance of the User program / OS on the monitored host. The monitoring result is reported from an agent of the management tool A to the manager, then the manager of the management tool issues a JP1 event and notifies it to JP1/IM.

Figure 7–5: Operation and configuration using management tool A

The following figure shows the tree structure when management tool A is managed by Intelligent Integrated Management Base.

Figure 7–6: the tree structure when management tool A is managed by Intelligent Integrated Management Base

## 7.5.2 Example for the management node SID of the management tool A

The following table shows example SID for Manager host A and Agent host B of Management tool A.

Table 7–44: SID for Manager host A and Agent host B of Management tool A

## 7.5.3 JP1 event issued by management tool A

The following is an example of the JP1 event issued by the management tool A, for an event occurred on the Agent host D.

Table 7–45: The JP1 event issued by the management tool A, for an event occurred on the Agent host D

| Event type         | Event ID   | B.SOURCESERVER | E.TOOLA_AGTHOST | E.UP_NAME |
|--------------------|------------|----------------|-----------------|-----------|
| ToolA-Agent Event  | 0x7FFF8000 | hostA          | hostD           | None      |
| OSMonitoring Event | 0x7FFF8001 | hostA          | hostD           | None      |
| UPMonitoring Event | 0x7FFF8002 | hostA          | hostD           | UP-3      |

## 7.5.4 Sample plugin

Following is a sample plug-in when managing the management tool A by the Intelligent Integrated Management Base.

```

| 13   | DC3   | Device Control 3 (Device control 3)                   |
| 14   | DC4   | Device Control 4 (Device control 4)                   |
| 15   | NAK   | Negative AcKnowledge (Negative acknowledgement)       |
| 16   | SYN   | SYNchronous idle (Synchronization signal)             |
| 17   | ETB   | End of Transmission Block (End of transmission block) |
| 18   | CAN   | CANcel (Cancel)                                       |
| 19   | EM    | End of Medium (End of medium)                         |
| 1A   | SUB   | SUBstitute (Substitution)                             |
| 1B   | ESC   | ESCape (Extended)                                     |
| 1C   | FS    | File Separator (File separator)                       |
| 1D   | GS    | Group Separator (Group separator)                     |
| 1E   | RS    | Record Separator (Record separator)                   |

| Code | Value | Description                                                                             |
|------|-------|-----------------------------------------------------------------------------------------|
| 1F   | US    | Unit Separator (Unit separator)                                                         |
| 7F   | DEL   | DELeTe (Delete)                                                                         |
| 80   | PAD   | PADding character (Padding character)                                                   |
| 81   | HOP   | High Octet Preset (High Octet Preset)                                                   |
| 82   | BPH   | Break Permitted Here (Break permission)                                                 |
| 83   | NBH   | No Break Here (Break prohibition)                                                       |
| 84   | IND   | INDeX (Index)                                                                           |
| 85   | NEL   | NEExt Line (New line)                                                                   |
| 86   | SSA   | Start of Selected Area (Start of selected area)                                         |
| 87   | ESA   | End of Selected Area (End of selected area)                                             |
| 88   | HTS   | Horizontal Tabulation Set (Horizontal tabulation set)                                   |
| 89   | HTJ   | Horizontal Tabulation with Justification (Horizontal tabulation set with justification) |
| 8A   | VTs   | Vertical Tabulation Set (Vertical tabulation set)                                       |
| 8B   | PLD   | Partial Line Down (Partial line down)                                                   |
| 8C   | PLU   | Partial Line Up (Partial line up)                                                       |
| 8D   | RI    | Reverse line feed (Previous page)                                                       |
| 8E   | SS2   | Single Shift 2 (Single character shift 2)                                               |
| 8F   | SS3   | Single Shift 3 (Single character shift 3)                                               |
| 90   | DCS   | Device Control String (Device control string)                                           |
| 91   | PU1   | Private Use 1 (Private use 1)                                                           |
| 92   | PU2   | Private Use 2 (Private use 2)                                                           |
| 93   | STS   | Set Transmit State (Transmission state setting)                                         |
| 94   | CCH   | Cancel CHaracter (Cancel character)                                                     |
| 95   | MW    | Message Waiting (Waiting for message)                                                   |
| 96   | SPA   | Start of Protected Area (Start of protected area)                                       |
| 97   | EPA   | End of Protected Area (End of protected area)                                           |
| 98   | SOS   | Start Of String (Start of string)                                                       |
| 99   | SGCI  | Single Graphic Character Introducer (Start of single graphic character)                 |
| 9A   | SCI   | Single Character Introducer (Start of single character)                                 |
| 9B   | CSI   | Control Sequence Introducer (Start of control sequence)                                 |
| 9C   | ST    | String Terminator (End of string)                                                       |
| 9D   | OSC   | Operating System Command (OScommand)                                                    |
| 9E   | PM    | Privacy Message (Private message)                                                       |
| 9F   | APC   | Application Program Command (AP command)                                                |

# 8

## **Lists of System-Monitoring Objects (for Central Scope)**

This chapter describes the system-monitoring objects provided by JP1/IM.

## 8.1 About system-monitoring objects

---

System-monitoring objects are provided by the system, and the basic setting items for each product are already defined.

For details about functions related to monitoring trees and monitoring objects to be described in this chapter, and how to view tables, see *5.2 Monitoring tree* in the *JP1/Integrated Management 3 - Manager Overview and System Design Guide*. Also, for details about how to set monitoring trees or monitoring objects, see *6.3 Using the GUI to create a monitoring tree* in the *JP1/Integrated Management 3 - Manager Configuration Guide*.

## 8.2 List of products for which system-monitoring objects are supported

The table below lists the products for which JP1/IM - Manager provides system-monitoring objects and, for each product, indicates whether the automatic generation function is supported.

### Support of the automatic generation function for products for which JP1/IM - Manager provides system-monitoring objects

Table 8–1: Products for which JP1/IM - Manager provides system-monitoring objects and the automatic generation function support status

| Product name                                         | Automatic generation function |
|------------------------------------------------------|-------------------------------|
| JP1/AJS2 07-00 or later, JP1/AJS3 09-00 or later     | Supported <sup>#3</sup>       |
| JP1/Cm2/SSO Version 7 or Version 8 <sup>#1, #2</sup> | Supported <sup>#3</sup>       |
| JP1/Cm2/SSO 07-00 or later <sup>#1, #2</sup>         | Supported <sup>#3</sup>       |
| JP1/PFM 07-00 or later                               | Supported <sup>#3</sup>       |
| JP1/PAM 07-00 or later                               | Not supported                 |
| JP1/Software Distribution 07-00 or later             | Not supported                 |
| HP NNM Version 7 or Version 8 <sup>#2</sup>          | Not supported                 |
| JP1/NNMi                                             | Not supported                 |
| JP1/IM - Central Console 07-00 or later              | Supported <sup>#3</sup>       |
| Cosminexus 06-00 or later                            | Supported <sup>#3</sup>       |
| HiRDB 07-02 or later                                 | Not supported                 |

#1: The product name for version 7 is JP1/PFM/SSO.

#2: To use the automatic generation function, JP1/Base Version 7 or Version 8 must be installed on the host where the linked product is installed.

#3: To use the automatic generation function, JP1/Base version 07-00 or later must be installed on the host where the linked product is installed. You also need an installed copy of JP1/IM - View with the same version as JP1/IM - Manager.

## 8.3 System-monitoring objects for JP1/AJS

The AJS Monitoring Object and Jobnet Monitoring (AJS) system-monitoring objects are provided For JP1/AJS.

### 8.3.1 AJS Monitoring system-monitoring object

Table 8–2: Overview of the system-monitoring object

| Item                 | Description                                                                   |                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Monitoring node type | AJS Monitoring Object                                                         |                                                                                                                                     |
| Purpose              | Monitoring of JP1/AJS itself for failures and for the jobnet execution status |                                                                                                                                     |
| Basic information    | Object name                                                                   | Complete name of the jobnet ( <i>scheduler-service-name</i> : / <i>jobnet-name</i> )<br>Example: AJSROOT1 : /Job_A/Order_Processing |
|                      | Host name                                                                     | Host name of the manager where JP1/AJS - Manager is installed<br>Example: host01                                                    |

Table 8–3: Status change conditions

| Status change condition    |         | Common condition <sup>#</sup> and individual condition |                   |                                                                               |
|----------------------------|---------|--------------------------------------------------------|-------------------|-------------------------------------------------------------------------------|
| Condition name             | Status  | Condition                                              |                   | Values to be compared                                                         |
| Jobnet warning event (AJS) | Warning | Jobnet warning event (AJS) <sup>#</sup>                | Event ID (B . ID) | 00004108,<br>00004122, 00004123                                               |
|                            |         | Object ID (E . OBJECT_NAME)                            |                   | Object name in the basic information                                          |
|                            |         | Event-issuing server name (B . SOURCESERVER)           |                   | Host name in the basic information                                            |
| Jobnet error event (AJS)   | Error   | Jobnet error event (AJS) <sup>#</sup>                  | Event ID (B . ID) | 00004104,<br>00004131, 00004142,<br>00004143, 00004144                        |
|                            |         | Object ID (E . OBJECT_NAME)                            |                   | Object name in the basic information                                          |
|                            |         | Event-issuing server name (B . SOURCESERVER)           |                   | Host name in the basic information                                            |
| System warning event (AJS) | Warning | System warning event (AJS) <sup>#</sup>                | Event ID (B . ID) | 00004154, 00004164,<br>00004171, 000041F1                                     |
|                            |         | Event-issuing server name (B . SOURCESERVER)           |                   | Host name in the basic information                                            |
| System error event (AJS)   | Error   | System error event (AJS) <sup>#</sup>                  | Event ID (B . ID) | 00004110,<br>00004130, 00004152,<br>00004162, 00004170,<br>000041F0, 000041F3 |
|                            |         | Event-issuing server name (B . SOURCESERVER)           |                   | Host name in the basic information                                            |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

## 8.3.2 Jobnet Monitoring (AJS) system-monitoring object

Table 8–4: Overview of the system-monitoring object

| Item                 | Description                        |                                                                                                                                               |
|----------------------|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Monitoring node type | Jobnet Monitoring (AJS)            |                                                                                                                                               |
| Purpose              | Monitoring of job execution status |                                                                                                                                               |
| Basic information    | Job execution host                 | Name of the host that executes the job<br>Example: jpl-agent                                                                                  |
|                      | Event-issuing server               | Name of the host where JP1/AJS - Manager is installed<br>Example: jpl-manager                                                                 |
|                      | Registration name                  | Complete name of the root jobnet ( <i>scheduler-service-name</i> : / <i>root-jobnet-name</i> )<br>Example: AJSROOT1 : /Job_A/Order_Processing |

Table 8–5: Status change conditions

| Status change condition |         | Common condition <sup>#</sup> and individual condition |                   |                                               |
|-------------------------|---------|--------------------------------------------------------|-------------------|-----------------------------------------------|
| Condition name          | Status  | Condition                                              |                   | Values to be compared                         |
| Job warning event (AJS) | Warning | Job warning event (AJS) <sup>#</sup>                   | Event ID (B . ID) | 00004109                                      |
|                         |         | Registration name (E . ROOT_OBJECT_NAME)               |                   | Registration name in the basic information    |
|                         |         | Execution host name (E . CO)                           |                   | Job execution host in the basic information   |
|                         |         | Event-issuing server name (B . SOURCESERVER)           |                   | Event-issuing server in the basic information |
| Job error event (AJS)   | Error   | Job error event (AJS) <sup>#</sup>                     | Event ID (B . ID) | 00004107                                      |
|                         |         | Registration name (E . ROOT_OBJECT_NAME)               |                   | Registration name in the basic information    |
|                         |         | Execution host name (E . CO)                           |                   | Job execution host in the basic information   |
|                         |         | Event-issuing server name (B . SOURCESERVER)           |                   | Event-issuing server in the basic information |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

## 8.4 System-monitoring objects for JP1/Cm2/SSO

The SSO Monitoring, category monitoring (SSO), and application monitoring (SSO) system-monitoring objects are provided for JP1/Cm2/SSO version 8 or earlier.

### 8.4.1 Settings for monitoring system-monitoring objects for JP1/Cm2/SSO version 8 or earlier

This subsection provides necessary settings for monitoring system-monitoring objects for JP1/Cm2/SSO version 8 or earlier. The following items must be set:

- Because JP1/Cm2/SSO version 8 or earlier does not issue JP1 events, you must use the JP1/Base function to convert SNMP traps (issued by JP1/Cm2/SSO for HP NNM version 7.5 or earlier) into JP1 events. During the conversion, you must use the SNMP trap conversion function of JP1/Base to set capturing of the variable binding of an SNMP trap.
- To monitor *application monitoring* (SSO), you must edit the definition file (`ssoapmon.def`) for JP1/Cm2/SSO version 8 or earlier so that the source name of the variable binding for an SNMP trap is captured.

### 8.4.2 SSO Monitoring system-monitoring object

Table 8–6: Overview of the system-monitoring object

| Item                 | Description                                                       |                                                                                                                      |
|----------------------|-------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| Monitoring node type | SSO Monitoring                                                    |                                                                                                                      |
| Purpose              | Monitoring of failures in JP1/Cm2/SSO version 8 or earlier itself |                                                                                                                      |
| Basic information    | Host name                                                         | Host name of a monitoring server where JP1/Cm2/SSO version 8 or earlier is installed<br>Example: <code>host01</code> |

Table 8–7: Status change conditions

| Status change condition  |        | Common condition <sup>#1</sup> and individual condition |                             |                                    |
|--------------------------|--------|---------------------------------------------------------|-----------------------------|------------------------------------|
| Condition name           | Status | Condition                                               |                             | Values to be compared              |
| System Alert event (SSO) | Alert  | System Alert event (SSO) <sup>#1</sup>                  | Event ID (B.ID)             | 00003A80                           |
|                          |        |                                                         | SNMP Object ID (E.SNMP_OID) | ---.15 <sup>#2</sup>               |
|                          |        | Event-issuing host name (E.SNMP_VARBIND6)               |                             | Host name in the basic information |
| System error event (SSO) | Error  | System error event (SSO) <sup>#1</sup>                  | Event ID (B.ID)             | 00003A80                           |
|                          |        |                                                         | SNMP Object ID (E.SNMP_OID) | ---.13 <sup>#2</sup>               |
|                          |        | Event-issuing host name (E.SNMP_VARBIND6)               |                             | Host name in the basic information |

#1: This is a common condition (condition commonly used in monitoring objects).

#2: --- is replaced with `.iso.org.dod.internet.private.enterprises.hitachi.systemAP.comet.sso.0`.

## 8.4.3 Category Monitoring (SSO) system-monitoring object

Table 8–8: Overview of the system-monitoring object

| Item                 | Description                                                                     |                                                                                                         |
|----------------------|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Monitoring node type | Category Monitoring (SSO)                                                       |                                                                                                         |
| Purpose              | Monitoring of the resource status monitored by JP1/Cm2/SSO version 8 or earlier |                                                                                                         |
| Basic information    | Category name                                                                   | Category name                                                                                           |
|                      | Event-issuing host name                                                         | Host name of a monitoring server where JP1/Cm2/SSO version 8 or earlier is installed<br>Example: host01 |
|                      | Host name                                                                       | Host name of a server monitored by JP1/Cm2/SSO version 8 or earlier<br>Example: host02                  |

Table 8–9: Status change conditions

| Status change condition    |        | Common condition <sup>#1</sup> and individual condition |                                |                                                  |
|----------------------------|--------|---------------------------------------------------------|--------------------------------|--------------------------------------------------|
| Condition name             | Status | Condition                                               |                                | Values to be compared                            |
| Resource Alert event (SSO) | Alert  | Resource Alert event (SSO) <sup>#1</sup>                | Event ID (B . ID)              | 00003A80                                         |
|                            |        |                                                         | SNMP Object ID (E . SNMP _OID) | --- . 24 <sup>#2</sup>                           |
|                            |        | Source name (E . SNMP _VARBIND12)                       |                                | Host name in the basic information               |
|                            |        | Event-issuing host name (E . SNMP _VARBIND11)           |                                | Event-issuing host name in the basic information |
|                            |        | Category name (E . SNMP _VARBIND2)                      |                                | Category name in the basic information           |
| Resource error event (SSO) | Error  | Resource error event (SSO) <sup>#1</sup>                | Event ID (B . ID)              | 00003A80                                         |
|                            |        |                                                         | SNMP Object ID (E . SNMP _OID) | --- . (21   23) <sup>#2</sup>                    |
|                            |        | Source name (E . SNMP _VARBIND12)                       |                                | Host name in the basic information               |
|                            |        | Event-issuing host name (E . SNMP _VARBIND11)           |                                | Event-issuing host name in the basic information |
|                            |        | Category name (E . SNMP _VARBIND2)                      |                                | Category name in the basic information           |

#1: This is a common condition (condition commonly used in monitoring objects).

#2: --- is replaced with .iso.org.dod.internet.private.enterprises.hitachi.systemAP.comet.sso.0.

## 8.4.4 Application Monitoring (SSO) system-monitoring object

Table 8–10: Overview of the system-monitoring object

| Item                 | Description                                                                        |
|----------------------|------------------------------------------------------------------------------------|
| Monitoring node type | Application Monitoring (SSO)                                                       |
| Purpose              | Monitoring of the application status monitored by JP1/Cm2/SSO version 8 or earlier |

| Item              | Description             |                                                                                                                                |
|-------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| Basic information | Event-issuing host name | Host name of a monitoring server where JP1/Cm2/SSO version 8 or earlier is installed<br>Example: host01                        |
|                   | Application name        | Name of an application monitored by JP1/Cm2/SSO version 8 or earlier<br>Example:JP1 / PFM                                      |
|                   | Host name               | Host name of a server whose resources are to be collected and monitored by JP1/Cm2/SSO version 8 or earlier<br>Example: host02 |

Table 8–11: Status change conditions

| Status change condition                        |        | Common condition <sup>#1</sup> and individual condition      |                                |                                                         |
|------------------------------------------------|--------|--------------------------------------------------------------|--------------------------------|---------------------------------------------------------|
| Condition name                                 | Status | Condition                                                    |                                | Values to be compared                                   |
| Application Alert event (SSO)                  | Alert  | Application Alert event (SSO) <sup>#1</sup>                  | Event ID (B . ID)              | 00003A80                                                |
|                                                |        |                                                              | SNMP Object ID (E . SNMP _OID) | --- . (109   112   115) <sup>#2</sup>                   |
|                                                |        | Source name (E . SNMP _VARBIND3)                             |                                | Host name in the basic information                      |
|                                                |        | Event-issuing host name (E . SNMP _VARBIND2)                 |                                | Event-issuing host name in the basic information        |
|                                                |        | Application name (E . SNMP _VARBIND1)                        |                                | Application name in the basic information               |
| Application error event (SSO)                  | Error  | Application Alert event (SSO) <sup>#1</sup>                  | Event ID (B . ID)              | 00003A80                                                |
|                                                |        |                                                              | SNMP Object ID (E . SNMP _OID) | --- . (108   110   111   113   116   118) <sup>#2</sup> |
|                                                |        | Source name (E . SNMP _VARBIND3)                             |                                | Host name in the basic information                      |
|                                                |        | Event-issuing host name (E . SNMP _VARBIND2)                 |                                | Event-issuing host name in the basic information        |

|                                                |        |                                                              | SNMP Object ID (E . SNMP _OID) | --- .304 <sup>#2</sup>                                  |
|                                                |        | Host name of a monitored machine (E . SNMP _VARBIND1)        |                                | Host name in the basic information                      |
|                                                |        | Event-issuing host name (E . SNMP _VARBIND4)                 |                                | Event-issuing host name in the basic information        |
| Process monitoring failure error event (SSO)   | Error  | Process monitoring failure error event (SSO) <sup>#1</sup>   | Event ID (B . ID)              | 00003A80                                                |
|                                                |        |                                                              | SNMP Object ID (E . SNMP _OID) | ---.303 <sup>#2</sup>                                   |
|                                                |        | Host name of a monitored machine (E . SNMP _VARBIND1)        |                                | Host name in the basic information                      |
|                                                |        | Event-issuing host name (E . SNMP _VARBIND4)                 |                                | Event-issuing host name in the basic information        |

#1: This is a common condition (condition commonly used in monitoring objects).

#2: --- is replaced with .iso.org.dod.internet.private.enterprises.hitachi.systemAP.comet.sso.0.

## 8.5 System-monitoring objects for JP1/PFM

The Agent Monitoring (PFM) system-monitoring objects are provided for JP1/PFM.

### 8.5.1 Settings for monitoring system-monitoring objects for JP1/PFM

This subsection explains the necessary settings for monitoring system-monitoring objects for JP1/PFM. The following items must be set:

- To manage events issued by JP1/PFM - Manager, you must specify the alarm settings of JP1/PFM - Manager in such a manner that a JP1 event is issued as an action of command execution when the alarm status changes (this is because the default setting does not issue JP1/events).

### 8.5.2 Agent Monitoring (PFM) system-monitoring object

Table 8–12: Overview of the system-monitoring object

| Item                 | Description                                   |                                                                               |
|----------------------|-----------------------------------------------|-------------------------------------------------------------------------------|
| Monitoring node type | Agent Monitoring (PFM)                        |                                                                               |
| Purpose              | Monitoring of the status of the JP1/PFM agent |                                                                               |
| Basic information    | Object ID                                     | Service ID of the JP1/PFM agent<br>Example: TA1host01                         |
|                      | Event-issuing server                          | Name of the host where JP1/PFM - Manager is installed<br>Example: pfm-manager |
|                      | Host name                                     | Name of the host where JP1/PFM - Agent is installed<br>Example: pfm-agent     |

Table 8–13: Status change conditions

| Status change condition      |         | Common condition <sup>#1</sup> and individual condition   |                                 |                                               |
|------------------------------|---------|-----------------------------------------------------------|---------------------------------|-----------------------------------------------|
| Condition name               | Status  | Condition                                                 |                                 | Values to be compared                         |
| Resource error event (PFM)   | Error   | Resource error event (PFM) <sup>#2</sup>                  | Event level (E . SEVERITY)      | Error                                         |
|                              |         |                                                           | Product name (E . PRODUCT_NAME) | /PFM/ALARM_EVENT                              |
|                              |         | Object ID (E . OBJECT_ID)                                 |                                 | Object ID in the basic information            |
|                              |         | Name of the host where the alarm occurred (E . JPC_AGENT) |                                 | Host name in the basic information            |
|                              |         | Event-issuing server name (B . SOURCESERVER)              |                                 | Event-issuing server in the basic information |
| Resource warning event (PFM) | Warning | Resource warning event (PFM) <sup>#1</sup>                | Event level (E . SEVERITY)      | Warning                                       |
|                              |         |                                                           | Product name (E . PRODUCT_NAME) | /PFM/ALARM_EVENT                              |

| Status change condition |        | Common condition <sup>#1</sup> and individual condition   |                                               |
|-------------------------|--------|-----------------------------------------------------------|-----------------------------------------------|
| Condition name          | Status | Condition                                                 | Values to be compared                         |
|                         |        | Object ID (E . OBJECT_ID)                                 | Object ID in the basic information            |
|                         |        | Name of the host where the alarm occurred (E . JPC_AGENT) | Host name in the basic information            |
|                         |        | Event-issuing server name (B . SOURCESERVER)              | Event-issuing server in the basic information |

#1: This is a common condition (condition commonly used in monitoring objects).

#2: The JP1/PFM service is identified by the product ID and function ID contained in the service ID. The following services are supported:

- Service whose product ID is not P (PFM - Manager)
- Service whose function ID is A (Agent Collector)

## 8.6 System-monitoring objects for JP1/PAM

The Metric Monitoring (PAM) and Object Monitoring (PAM) system-monitoring objects are provided for JP1/PAM.

### 8.6.1 Metric Monitoring (PAM) system-monitoring object

Table 8–14: Overview of the system-monitoring object

| Item                 | Description                                |                                                         |
|----------------------|--------------------------------------------|---------------------------------------------------------|
| Monitoring node type | Metric Monitoring (PAM)                    |                                                         |
| Purpose              | Monitoring of the metric status of JP1/PAM |                                                         |
| Basic information    | Host name                                  | Name of the host monitored by JP1/PAM<br>Example: host1 |

Table 8–15: Status change conditions

| Status change condition    |         | Common condition <sup>#</sup> and individual condition |                   |                                    |
|----------------------------|---------|--------------------------------------------------------|-------------------|------------------------------------|
| Condition name             | Status  | Condition                                              |                   | Values to be compared              |
| Metric error event (PAM)   | Error   | Metric error event (PAM) <sup>#</sup>                  | Event ID (B . ID) | 00004602,<br>00004604, 0000460B    |
|                            |         | Host name (E . PAM_HOSTNAME)                           |                   | Host name in the basic information |
| Metric warning event (PAM) | Warning | Metric warning event (PAM) <sup>#</sup>                | Event ID (B . ID) | 00004600,<br>00004603, 00004609    |
|                            |         | Host name (E . PAM_HOSTNAME)                           |                   | Host name in the basic information |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

### 8.6.2 Object Monitoring (PAM) system-monitoring object

Table 8–16: Overview of the system-monitoring object

| Item                 | Description                                            |                                                         |
|----------------------|--------------------------------------------------------|---------------------------------------------------------|
| Monitoring node type | Object monitoring (PAM)                                |                                                         |
| Purpose              | Monitoring of the status of objects managed by JP1/PAM |                                                         |
| Basic information    | Host name                                              | Name of the host monitored by JP1/PAM<br>Example: host1 |

Table 8–17: Status change conditions

| Status change condition  |        | Common condition <sup>#</sup> and individual condition |                   |                       |
|--------------------------|--------|--------------------------------------------------------|-------------------|-----------------------|
| Condition name           | Status | Condition                                              |                   | Values to be compared |
| Object error event (PAM) | Error  | Object error event (PAM) <sup>#</sup>                  | Event ID (B . ID) | 00004620, 00004625    |

| Status change condition |        | Common condition <sup>#</sup> and individual condition |                                    |
|-------------------------|--------|--------------------------------------------------------|------------------------------------|
| Condition name          | Status | Condition                                              | Values to be compared              |
|                         |        | Host name (E . PAM_HOSTNAME)                           | Host name in the basic information |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

## 8.7 System-monitoring objects for JP1/Software Distribution

The SD Monitoring and Distribution Job Monitoring (SD) system-monitoring objects are provided for JP1/Software Distribution.

### 8.7.1 SD Monitoring system-monitoring object

Table 8–18: Overview of the system-monitoring object

| Item                 | Description                                                         |                                                                                                  |
|----------------------|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Monitoring node type | SD Monitoring                                                       |                                                                                                  |
| Purpose              | Monitoring of JP1/Software Distribution Manager itself for failures |                                                                                                  |
| Basic information    | Host name                                                           | Host name of the manager where JP1/Software Distribution Manager is installed<br>Example: host01 |

Table 8–19: Status change conditions

| Status change condition         |          | Common condition <sup>#</sup> and individual condition |                   |                                    |
|---------------------------------|----------|--------------------------------------------------------|-------------------|------------------------------------|
| Condition name                  | Status   | Condition                                              |                   | Values to be compared              |
| Critical system event (NETM/DM) | Critical | Critical system event (NETM/DM) <sup>#</sup>           | Event ID (B . ID) | 00010401                           |
|                                 |          | Event-issuing server name (B . SOURCESERVER)           |                   | Host name in the basic information |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

### 8.7.2 Distribution Job Monitoring (SD) system-monitoring object

Table 8–20: Overview of the system-monitoring object

| Item                 | Description                                                                          |                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Monitoring node type | Distribution Job Monitoring (SD)                                                     |                                                                                                  |
| Purpose              | Monitoring of the execution status of distribution jobs by JP1/Software Distribution |                                                                                                  |
| Basic information    | Host name                                                                            | Host name of the manager where JP1/Software Distribution Manager is installed<br>Example: host01 |

Table 8–21: Status change conditions

| Status change condition                              |        | Common condition <sup>#</sup> and individual condition            |                   |                                    |
|------------------------------------------------------|--------|-------------------------------------------------------------------|-------------------|------------------------------------|
| Condition name                                       | Status | Condition                                                         |                   | Values to be compared              |
| Distribution job error event (Software Distribution) | Error  | Distribution job error event (Software Distribution) <sup>#</sup> | Event ID (B . ID) | 00010403                           |
|                                                      |        | Event-issuing server name (B . SOURCESERVER)                      |                   | Host name in the basic information |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

## 8.8 JP1/NNMi-type system-monitoring objects

The NNMi monitoring (NNMi) and node monitoring (NNMi) system-monitoring objects are provided for JP1/NNMi.

### 8.8.1 Settings for monitoring system-monitoring objects for JP1/NNMi

This subsection explains the settings required when monitoring JP1/NNMi-type system-monitoring objects. When monitoring NNMi incidents issued by JP1/NNMi, management incidents and SNMP traps are not differentiated.

When using NNMi monitoring (NNMi) or node monitoring (NNMi), set the extended attribute (NNMI\_FAMILY\_UK) for the JP1 event converted from the NNMi incident issued by JP1/IM - EG for NNMi.

If you do not set the NNMI\_FAMILY\_UK extended attribute, you cannot perform monitoring by using NNMi monitoring (NNMi) or node monitoring (NNMi).

For details about setting the NNMI\_FAMILY\_UK extended attribute and NNMi incidents, see the *Job Management Partner 1/Integrated Management 3 - Event Gateway for Network Node Manager i Description, User's Guide and Reference*.

### 8.8.2 NNMi Monitoring system-monitoring object

Table 8–22: Overview of the system-monitoring object

| Item                 | Description                                |                                                                         |
|----------------------|--------------------------------------------|-------------------------------------------------------------------------|
| Monitoring node type | NNMi Monitoring                            |                                                                         |
| Purpose              | Monitoring of JP1/NNMi itself for failures |                                                                         |
| Basic information    | Host name                                  | Host name of the manager where JP1/NNMi is installed<br>Example: host01 |

Table 8–23: Status change conditions

| Status change condition      |          | Common condition <sup>#</sup> and individual condition           |                 |                       |
|------------------------------|----------|------------------------------------------------------------------|-----------------|-----------------------|
| Condition name               | Status   | Condition                                                        |                 | Values to be compared |
| System alert event (NNMi)    | Alert    | System alert event (NNMi) <sup>#</sup>                           | Event ID (B.ID) | 00006100              |
|                              |          | Name of the node where the event occurred (E.NNMI_SRC_NODE_NAME) |                 | Host name             |
| Critical system event (NNMi) | Critical | Critical system event (NNMi) <sup>#</sup>                        | Event ID (B.ID) | 00006100              |
|                              |          | Name of the node where the event occurred (E.NNMI_SRC_NODE_NAME) |                 | Host name             |
| System warning event (NNMi)  | Warning  | System warning event (NNMi) <sup>#</sup>                         | Event ID (B.ID) | 00006100              |

| Status change condition |        | Common condition <sup>#</sup> and individual condition           |                       |
|-------------------------|--------|------------------------------------------------------------------|-----------------------|
| Condition name          | Status | Condition                                                        | Values to be compared |
|                         |        | Name of the node where the event occurred (E.NNMI_SRC_NODE_NAME) | Host name             |

<sup>#</sup>: This is a common condition (condition used in common by monitoring objects).

### 8.8.3 Node Monitoring (NNMi) system-monitoring object

Table 8–24: Overview of the system-monitoring object

| Item                 | Description                                             |                                                                 |
|----------------------|---------------------------------------------------------|-----------------------------------------------------------------|
| Monitoring node type | Node Monitoring (NNMi)                                  |                                                                 |
| Purpose              | Monitoring of the status of nodes monitored by JP1/NNMi |                                                                 |
| Basic information    | Host name                                               | Host name of the node monitored by JP1/ NNMi<br>Example: host01 |

Table 8–25: Status change conditions

| Status change condition       |          | Common condition <sup>#</sup> and individual condition           |                 |                                    |
|-------------------------------|----------|------------------------------------------------------------------|-----------------|------------------------------------|
| Condition name                | Status   | Condition                                                        |                 | Values to be compared              |
| Network alert event (NNMi)    | Alert    | Network alert event (NNMi) <sup>#</sup>                          | Event ID (B.ID) | 00006100                           |
|                               |          | Name of the node where the event occurred (E.NNMI_SRC_NODE_NAME) |                 | Host name in the basic information |
| Critical network event (NNMi) | Critical | Critical network event (NNMi) <sup>#</sup>                       | Event ID (B.ID) | 00006100                           |
|                               |          | Name of the node where the event occurred (E.NNMI_SRC_NODE_NAME) |                 | Host name in the basic information |
| Network warning event (NNMi)  | Warning  | Network warning event (NNMi) <sup>#</sup>                        | Event ID (B.ID) | 00006100                           |
|                               |          | Name of the node where the event occurred (E.NNMI_SRC_NODE_NAME) |                 | Host name in the basic information |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

## 8.9 System-monitoring objects for HP NNM

The NNM Monitoring and Node Monitoring (NNM) system-monitoring objects are provided for HP NNM version 8 or earlier.

### 8.9.1 NNM Monitoring system-monitoring object

Table 8–26: Overview of the system-monitoring object

| Item                 | Description                                                   |                                                                                            |
|----------------------|---------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| Monitoring node type | NNM Monitoring                                                |                                                                                            |
| Purpose              | Monitoring of HP NNM version 8 or earlier itself for failures |                                                                                            |
| Basic information    | Host name                                                     | Host name of the manager where HP NNM version 8 or earlier is installed<br>Example: host01 |

Table 8–27: Status change conditions

| Status change condition     |          | Common condition <sup>#1</sup> and individual condition        |                                |                                                                                                                                                                                                                                                             |
|-----------------------------|----------|----------------------------------------------------------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Condition name              | Status   | Condition                                                      |                                | Values to be compared                                                                                                                                                                                                                                       |
| System alert event (NNM)    | Alert    | System alert event (NNM) <sup>#1</sup>                         | Event ID (B . ID)              | 00003A80                                                                                                                                                                                                                                                    |
|                             |          |                                                                | SNMP Object ID (E . SNMP _OID) | ~.(50790429 58851330 59179066 59179227 59179229 59179230 40000020) <sup>#2</sup>                                                                                                                                                                            |
|                             |          | Name of the node where the event occurred (E . SNMP _VARBIND2) |                                | Host name in the basic information                                                                                                                                                                                                                          |

| System warning event (NNM) | Warning | System warning event (NNM) <sup>#1</sup>                    | Event ID (B.ID)             | 00003A80                                                            |
|                            |         |                                                             | SNMP Object ID (E.SNMP_OID) | ~.(40000027   58982399   59179065) <sup>#2</sup>                    |
|                            |         | Name of the node where the event occurred (E.SNMP_VARBIND2) |                             | Host name in the basic information                                  |

#1: This is a common condition (condition commonly used in monitoring objects).

#2: Replace ~ with .iso.org.dod.internet.private.enterprises.hp.nm.openView.hpOpenView.0.

## 8.9.2 Node Monitoring (NNM) system-monitoring object

Table 8–28: Overview of the system-monitoring object

| Item                 | Description                                                                |                                                                                   |
|----------------------|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Monitoring node type | Node Monitoring (NNM)                                                      |                                                                                   |
| Purpose              | Monitoring of the status of nodes monitored by HP NNM version 8 or earlier |                                                                                   |
| Basic information    | Host name                                                                  | Host name of the node monitored by HP NNM version 8 or earlier<br>Example: host01 |

Table 8–29: Status change conditions

| Status change condition      |          | Common condition <sup>#1</sup> and individual condition     |                             |                                                                        |
|------------------------------|----------|-------------------------------------------------------------|-----------------------------|------------------------------------------------------------------------|
| Condition name               | Status   | Condition                                                   |                             | Values to be compared                                                  |
| Critical network event (NNM) | Critical | Critical network event (NNM) <sup>#1</sup>                  | Event ID (B.ID)             | 00003A80                                                               |
|                              |          |                                                             | SNMP Object ID (E.SNMP_OID) | ~.58916868 <sup>#2</sup>                                               |
|                              |          | Name of the node where the event occurred (E.SNMP_VARBIND2) |                             | Host name in the basic information                                     |
| Network warning event (NNM)  | Warning  | Network warning event (NNM) <sup>#1</sup>                   | Event ID (B.ID)             | 00003A80                                                               |
|                              |          |                                                             | SNMP Object ID (E.SNMP_OID) | ~.(40000083   40000084   40000085   50790400   58916865) <sup>#2</sup> |
|                              |          | Name of the node where the event occurred (E.SNMP_VARBIND2) |                             | Host name in the basic information                                     |

#1: This is a common condition (condition commonly used in monitoring objects).

#2: Replace ~ with .iso.org.dod.internet.private.enterprises.hp.nm.openView.hpOpenView.0.

## 8.10 System-monitoring objects for JP1/IM - Manager

The IM Monitoring system-monitoring object is provided for JP1/IM - Manager.

### 8.10.1 IM Monitoring system-monitoring object

Table 8–30: Overview of the system-monitoring object

| Item                 | Description                                        |                                                                                 |
|----------------------|----------------------------------------------------|---------------------------------------------------------------------------------|
| Monitoring node type | IM Monitoring                                      |                                                                                 |
| Purpose              | Monitoring of JP1/IM - Manager itself for failures |                                                                                 |
| Basic information    | Host name                                          | Host name of the manager where JP1/IM - Manager is installed<br>Example: host01 |

Table 8–31: Status change conditions

| Status change condition   |         | Common condition <sup>#</sup> and individual condition |                   |                                                                                                                |
|---------------------------|---------|--------------------------------------------------------|-------------------|----------------------------------------------------------------------------------------------------------------|
| Condition name            | Status  | Condition                                              |                   | Values to be compared                                                                                          |
| System warning event (IM) | Warning | System warning event (IM) <sup>#</sup>                 | Event ID (B . ID) | 000020E6,<br>000020E7, 00003F91                                                                                |
|                           |         | Event-issuing server name (B . SOURCESERVER)           |                   | Host name in the basic information                                                                             |
| System error event (IM)   | Error   | System error event (IM) <sup>#</sup>                   | Event ID (B . ID) | 00002010, 00002011,<br>00002012, 00002020,<br>00002021, 000020A0,<br>000020E2, 000020E5,<br>000020E8, 00003F90 |
|                           |         | Event-issuing server name (B . SOURCESERVER)           |                   | Host name in the basic information                                                                             |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

## 8.11 System-monitoring objects for Cosminexus

The Logical Server Monitoring (Cosminexus) and J2EE Application Monitoring (Cosminexus) system-monitoring objects are provided for Cosminexus.

### 8.11.1 Logical Server Monitoring (Cosminexus) system-monitoring object

Table 8–32: Overview of the system-monitoring object

| Item                 | Description                                                                   |                                                                      |
|----------------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------|
| Monitoring node type | Logical Server Monitoring (Cosminexus)                                        |                                                                      |
| Purpose              | Monitoring of JP1 events related to failures at the server level <sup>#</sup> |                                                                      |
| Basic information    | Domain name                                                                   | Domain name of the Cosminexus server<br>Example: DOM001              |
|                      | Logical host name                                                             | Name of the logical host monitored by Cosminexus<br>Example: APSV001 |

<sup>#</sup>: JP1 events whose event level is `Warning` or higher are monitored.

Table 8–33: Status change conditions

| Status change condition                     |           | Common condition <sup>#</sup> and individual condition   |                 |                                            |
|---------------------------------------------|-----------|----------------------------------------------------------|-----------------|--------------------------------------------|
| Condition name                              | Status    | Condition                                                |                 | Values to be compared                      |
| Logical server emergency event (Cosminexus) | Emergency | Logical server emergency event (Cosminexus) <sup>#</sup> | Event ID (B.ID) | 00012000, 00012080                         |
|                                             |           | Domain name (E.DOMAIN_NAME)                              |                 | Domain name in the basic information       |
|                                             |           | Logical server name (E.LOGICAL_SERVER_NAME)              |                 | Logical host name in the basic information |
| Logical server alert event (Cosminexus)     | Alert     | Logical server alert event (Cosminexus) <sup>#</sup>     | Event ID (B.ID) | 00012001, 00012081                         |
|                                             |           | Domain name (E.DOMAIN_NAME)                              |                 | Domain name in the basic information       |
|                                             |           | Logical server name (E.LOGICAL_SERVER_NAME)              |                 | Logical host name in the basic information |
| Logical server critical event (Cosminexus)  | Critical  | Logical server critical event (Cosminexus) <sup>#</sup>  | Event ID (B.ID) | 00012002, 00012082                         |
|                                             |           | Domain name (E.DOMAIN_NAME)                              |                 | Domain name in the basic information       |
|                                             |           | Logical server name (E.LOGICAL_SERVER_NAME)              |                 | Logical host name in the basic information |
| Logical server error event (Cosminexus)     | Error     | Logical server error event (Cosminexus) <sup>#</sup>     | Event ID (B.ID) | 00012003, 00012083                         |

| Status change condition                   |         | Common condition <sup>#</sup> and individual condition |                 |                                            |
|-------------------------------------------|---------|--------------------------------------------------------|-----------------|--------------------------------------------|
| Condition name                            | Status  | Condition                                              |                 | Values to be compared                      |
| Logical server warning event (Cosminexus) | Warning | Domain name (E.DOMAIN_NAME)                            |                 | Domain name in the basic information       |
|                                           |         | Logical server name (E.LOGICAL_SERVER_NAME)            |                 | Logical host name in the basic information |
|                                           |         | Logical server warning event (Cosminexus) <sup>#</sup> | Event ID (B.ID) | 00012004, 00012084                         |
|                                           |         | Domain name (E.DOMAIN_NAME)                            |                 | Domain name in the basic information       |
|                                           |         | Logical server name (E.LOGICAL_SERVER_NAME)            |                 | Logical host name in the basic information |
|                                           |         |                                                        |                 |                                            |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

## 8.11.2 J2EE Application Monitoring (Cosminexus) system-monitoring object

Table 8–34: Overview of the system-monitoring object

| Item                 | Description                                                                        |                                                                                                  |
|----------------------|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Monitoring node type | J2EE Application Monitoring (Cosminexus)                                           |                                                                                                  |
| Purpose              | Monitoring of JP1 events related to failures at the application level <sup>#</sup> |                                                                                                  |
| Basic information    | Domain name                                                                        | Domain name of the Cosminexus server<br>Example: DOM001                                          |
|                      | Logical host name                                                                  | Name of the logical host monitored by Cosminexus<br>Example: APSV001                             |
|                      | J2EE application name                                                              | Name of the J2EE application on the logical host that is monitored by Cosminexus<br>Example: API |

<sup>#</sup>: JP1 events whose event level is `Warning` or higher are monitored.

Table 8–35: Status change conditions

| Status change condition                       |           | Common condition <sup>#</sup> and individual condition     |                 |                                                |
|-----------------------------------------------|-----------|------------------------------------------------------------|-----------------|------------------------------------------------|
| Condition name                                | Status    | Condition                                                  |                 | Values to be compared                          |
| J2EE application emergency event (Cosminexus) | Emergency | J2EE application emergency event (Cosminexus) <sup>#</sup> | Event ID (B.ID) | 00012090, 000120D0                             |
|                                               |           | Domain name (E.DOMAIN_NAME)                                |                 | Domain name in the basic information           |
|                                               |           | Logical server name (E.LOGICAL_SERVER_NAME)                |                 | Logical host name in the basic information     |
|                                               |           | J2EE application name (E.APPLICATION_NAME)                 |                 | J2EE application name in the basic information |

#: This is a common condition (condition commonly used in monitoring objects).

## 8.12 System-monitoring objects for HiRDB

The HiRDB Monitoring system-monitoring objects are provided for HiRDB.

### 8.12.1 Settings for monitoring system-monitoring objects for HiRDB

This subsection provides necessary settings for monitoring system-monitoring objects for HiRDB. The following items must be set:

- To manage HiRDB-related events, you must specify settings in such a manner that the failure information managed by HiRDB is issued as JPI events (this is because the default setting does not issue JPI events).

### 8.12.2 HiRDB Monitoring system-monitoring object

Table 8–36: Overview of the system-monitoring object

| Item                 | Description                             |                                                              |
|----------------------|-----------------------------------------|--------------------------------------------------------------|
| Monitoring node type | HiRDB Monitoring                        |                                                              |
| Purpose              | Monitoring of HiRDB itself for failures |                                                              |
| Basic information    | Host name                               | Name of the host where HiRDB is installed<br>Example: host02 |
|                      | HiRDB identifier                        | Identifier for identifying HiRDB<br>Example: PDB1            |

Table 8–37: Status change conditions

| Status change condition |           | Common condition <sup>#</sup> and individual condition |                                 |                                           |
|-------------------------|-----------|--------------------------------------------------------|---------------------------------|-------------------------------------------|
| Condition name          | Status    | Condition                                              |                                 | Values to be compared                     |
| HiRDB emergency event   | Emergency | HiRDB emergency event <sup>#</sup>                     | Product name (E . PRODUCT_NAME) | /HITACHI/HiRDB                            |
|                         |           |                                                        | Event level (E . SEVERITY)      | Emergency                                 |
|                         |           | Event-issuing server name (B . SOURCESERVER)           |                                 | Host name in the basic information        |
|                         |           | Registration name (E . ROOT_OBJECT_NAME)               |                                 | HiRDB identifier in the basic information |
| HiRDB alert event       | Alert     | HiRDB alert event <sup>#</sup>                         | Product name (E . PRODUCT_NAME) | /HITACHI/HiRDB                            |
|                         |           |                                                        | Event level (E . SEVERITY)      | Alert                                     |
|                         |           | Event-issuing server name (B . SOURCESERVER)           |                                 | Host name in the basic information        |
|                         |           | Registration name (E . ROOT_OBJECT_NAME)               |                                 | HiRDB identifier in the basic information |
| HiRDB critical event    | Critical  | HiRDB critical event <sup>#</sup>                      | Product name (E . PRODUCT_NAME) | /HITACHI/HiRDB                            |

| Status change condition |         | Common condition <sup>#</sup> and individual condition |                                 |                                           |

|                         |         |                                                        | Event level (E . SEVERITY)      | Error                                     |
|                         |         | Event-issuing server name (B . SOURCESERVER)           |                                 | Host name in the basic information        |
|                         |         | Registration name (E . ROOT_OBJECT_NAME)               |                                 | HiRDB identifier in the basic information |
| HiRDB warning event     | Warning | HiRDB warning event <sup>#</sup>                       | Product name (E . PRODUCT_NAME) | /HITACHI/HiRDB                            |
|                         |         |                                                        | Event level (E . SEVERITY)      | Warning                                   |
|                         |         | Event-issuing server name (B . SOURCESERVER)           |                                 | Host name in the basic information        |
|                         |         | Registration name (E . ROOT_OBJECT_NAME)               |                                 | HiRDB identifier in the basic information |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

## 8.13 System-monitoring objects for JP1/ServerConductor

The Physical Host Monitoring (System Manager) system-monitoring objects are provided for JP1/ServerConductor.

### 8.13.1 Settings for monitoring system-monitoring objects for JP1/ServerConductor

This subsection provides necessary settings for monitoring system-monitoring objects for JP1/ServerConductor. The following items must be set:

- To manage events related to a physical host managed by JP1/ServerConductor, you must set an alert detected by the manager service of JP1/ServerConductor to be issued as a JP1 event (this is because the default setting does not issue JP1 events).

### 8.13.2 Physical Host Monitoring (System Manager) Monitoring system-monitoring object

Table 8–38: Overview of the system-monitoring object

| Item                 | Description                                                                     |                                                                      |
|----------------------|---------------------------------------------------------------------------------|----------------------------------------------------------------------|
| Monitoring node type | Physical Host Monitoring (System Manager)                                       |                                                                      |
| Purpose              | Monitoring of failures related to physical hosts managed by JP1/ServerConductor |                                                                      |
| Basic information    | Host name                                                                       | Name of a physical host managed by System Manager<br>Example: host02 |

Table 8–39: Status change condition

| Status change condition       |           | Common condition <sup>#</sup> and individual condition                |                               |                                    |

|-----------------------------|---------|-------------------------------------------------------------------------|---------------------------------|------------------------------------|
| Condition name              | Status  | Condition                                                               |                                 | Values to be compared              |
|                             |         |                                                                         | Event level (E . SEVERITY)      | Critical                           |
|                             |         | Name of a physical host managed by JP1/ServerConductor (E . HSM_SERVER) |                                 | Host name in the basic information |
| Physical host error event   | Error   | Physical host error event <sup>#</sup>                                  | Product name (E . PRODUCT_NAME) | /HITACHI/SYSTEM_MANAGER            |
|                             |         |                                                                         | Event level (E . SEVERITY)      | Error                              |
|                             |         | Name of a physical host managed by JP1/ServerConductor (E . HSM_SERVER) |                                 | Host name in the basic information |
| Physical host warning event | Warning | Physical host warning event <sup>#</sup>                                | Product name (E . PRODUCT_NAME) | /HITACHI/SYSTEM_MANAGER            |
|                             |         |                                                                         | Event level (E . SEVERITY)      | Warning                            |
|                             |         | Name of a physical host managed by JP1/ServerConductor (E . HSM_SERVER) |                                 | Host name in the basic information |

<sup>#</sup>: This is a common condition (condition commonly used in monitoring objects).

# 9

## Monitoring Tree Models (for Central Scope)

This chapter describes the structure of monitoring trees that are generated automatically.

## 9.1 Templates used to generate monitoring trees automatically

---

The configuration of an automatically-generated monitoring tree varies depending on the template selected in the Auto-generation - Select Configuration window. The following templates are provided by Central Console:

- Work-oriented tree template
- Server-oriented tree template

Monitoring tree models are defined for each template. Use the definitions collected from each host to generate monitoring trees automatically according to the monitoring tree model.

## 9.2 Monitoring tree model for the work-oriented tree

The following figures show the monitoring tree model that is generated when the work-oriented tree template is selected for generating a monitoring tree automatically.

### Monitoring tree model generated when the work-oriented tree template is selected

Figure 9–1: Monitoring tree model (work-oriented tree template)

Figure 9–2: Monitoring tree model (work-oriented tree template)

Legend:

- Monitoring group name : Monitoring group
- Monitoring object name : Monitoring object
- Range generated when the linkage has been set up

### 9.3 Monitoring tree model for the server-oriented tree

The following figures show the monitoring tree model that is generated when the server-oriented tree template is selected for generating a monitoring tree automatically.

#### Monitoring tree model generated when the server-oriented tree template is selected

Figure 9–3: Monitoring tree model (server-oriented tree template)

Legend:

Monitoring group name : Monitoring group  
Monitoring object name : Monitoring object

: Range generated when the linkage has been set up

Figure 9–4: Monitoring tree model (server-oriented tree template)
